(*c.*) Resting larvæ, or *Cysticercus* (*telæ*) *cellulosæ* (scolex). }
(*d.*) Immature tapeworm.
(*e.*) Strobila, or sexually mature *Tænia solium*.
(*f.*) Proglottis (cucurbitinus) = free segment = deuterozooid.

—Cobbold, *Entozoa*, pp. 221, 222.

How long a T. can naturally exist in an intestinal canal, is not known; but there is doubtless a period at which the parasite spontaneously separates from the intestinal mucous membrane of its host—a period probably coinciding with the shedding and non-renewal of the circlet of hooks. When this separation occurs, the whole length of the worm is expelled, in the same manner as if the parasite had been first killed by the administration of a vermifuge medicine. From this history of the structure and life-history of this organism, which applies with slight difference in minor points to all other tapeworms, we proceed to describe the injurious effects which the worm in its adult and larval stages produces on man, and the precautions which should be taken to prevent its entrance into the system; while the discussion of the means of expelling it when it has once found a lodgment in the intestinal canal, will be postponed to the article on VERMIFUGES.

The common T. may cause disease, and even death, by its aggressions, either in the adult or in

the larval stage of its existence. A mature T. in the intestinal canal may give rise to a series of anomalous symptoms, including 'vertigo, noises in the ears, impairment of sight, itching of the nose and anus, salivation, dyspepsia, and loss of appetite, colic, pains over the epigastrium and in different parts of the abdomen, palpitation, syncope, the sensation of weight in the abdomen, pains and lassitude in the limbs, and emaciation.'—Davaine, *Traité des Entozoaires*, &c., p. 103. Many cases are on record in which hysterical fits, chorea, epilepsy, convulsions of various kinds, and even mania, have been induced by the irritation excited by this parasite, and have ceased at once on its removal. But distressing as these symptomatic phenomena may be, their injurious effects are trifling as compared with the troubles which follow the deposition and growth of the larval form within the body, especially when the cysticerci find a home in the more important vital organs. There are at least a hundred cases on record in which the cysticercus has caused death by its development within the human brain. In the present state of our knowledge, it is impossible to diagnose these cases; and even if a correct diagnosis were possible, nothing could be done in the way of treatment. Epilepsy, with or without mania or imbecility, is commonly, but not invariably present in these cases. 'Cysticerci,' says Dr Cobbold, 'may develop themselves in almost any situation in the human body, but they occur most frequently in the subcutaneous, areolar, and intermuscular connective tissue; next, most commonly in the brain and eye, and lastly, in the substance of the heart and other viscera of the trunk.'—*Entozoa*, p. 226. The *adult form of the worm* enters the system as the cysticercus of measly pork, and to eat raw or underdone measly pork is an almost certain means of introducing this parasite into the body. It is satisfactory to know that the temperature of boiling water is quite sufficient to destroy the vitality of the measles; and that in ordinary salted pork, and in hams, they are destroyed by the action of the salt in the one case, and of the combined salt and smoke in the other. Sausages, into which it is to be feared measly pork too often finds its way, are rendered safe if they are cooked till no pink, raw-like, fleshy look can be seen in their centre. Butchers are especially liable to T., in consequence of their touching and cutting measly pork, and then accidentally transferring the cysticercus by the hand, or even by the knife, to the mouth; and by indiscriminately using the same knife for various meats, both butchers and cooks may readily disseminate the infection over various articles of food. The *larval worm* may gain access into the human body by our swallowing the mature eggs of the tapeworm. Those who, as students of this department of natural history, handle fresh tapeworms, are perhaps especially liable to this misfortune; but, says Dr Cobbold, 'our neighbours, who devour choice salads, also run a certain amount of risk, not only as regards this entozoon, but as respects several others. The vegetables may be manured with night-soil containing myriads of tapeworm eggs, or they may be watered with fluid filth into which these eggs have been cast. In such cases, one or more tapeworm ova may be transferred to our digestive organs, unless the vegetables are carefully cleansed before they appear on the table. In the same way, one perceives how fallen fruits, all sorts of edible plants, as well as pond, canal, or even river water, procured from the neighbourhood of human habitations, are liable to harbour the embryos capable of gaining an entrance to our bodies. It thus becomes evident also how one individual suffering from tapeworm may infect a whole neighbourhood, rendering the swine measly, these animals in their turn spreading the disease far and wide.' Such a person may also prove dangerous—even fatal to his neighbours directly (without the intervention of a pig), by ejecting mature proglottides, from which thousands of eggs may escape, some of which may readily come in contact with human food or drink, make their way into the stomach, and from thence get into the circulation, and finally to the brain, where they cause convulsions and death. The most remarkable case on record of what may be termed a *measly* man, is one described, in 1864, by Delore, in the *Gazette Méd. de Paris*, and quoted by Dr Cobbold. He died at the age of 77, from pulmonary catarrh, old age, and fractured neck of the thigh-bone; and on examining his body after death, no less than 2000 cysticerci were found, of which 111 occurred in the nervous centres.

The T. that ranks next in importance to the *Tænia solium* is the *Tænia mediocanellata*, which was first established as a distinct species by Küchenmeister only a few years ago. It exceeds the *T. solium* both as regards length, breadth, and the thickness of the individual segments; the head is also somewhat larger, abruptly truncated at the crown, destitute of a proboscis and a hook-apparatus—hence this species has been described as the *hookless tapeworm*—but furnished with very large sucking-discs, surrounded by much dark pigment, which gives the head a blackish appearance. The specific name of *mediocanellata* has reference to an interesting and almost specific character in connection with the water-vascular system, into which we have not space to enter.

Fig. 4.

Head of *Tænia mediocanellata*, magnified about 35 diameters.

(From Cobbold.)

Leuckart has proved by experiment that the measles or cysticerci which produced this worm are to be found in the muscles and internal organs of cattle. He administered proglottides of *T. mediocanellata* to three calves, a sheep, and a pig. In the two last-named animals, they produced no effect, as was shewn by their post-mortem examination; while in the calves they produced a kind of leprosy, which has since been characterised as 'acute cestoid tuberculosis,' and which proved fatal if too large a dose of eggs was administered. On examining one of these animals after its restoration to health—48 days after the eggs were swallowed—he found numerous cysticercus-vesicles, larger and more opalescent than those of the pig, lodged within the muscles; and as the heads of the contained cysticerci exhibited the distinctive peculiarities presented by the head of the adult worm, 'we are supplied with the most unequivocal evidence that man becomes infested with this second form of tapeworm by eating imperfectly cooked veal and beef.' Hitherto, the two above-described species have commonly been included under *T. solium*, from want of due examination, especially of the head. Dr Cobbold believes that their respective frequency will ultimately be found pretty well on a par, though probably the *T. solium* will maintain a slight ascendency, in consequence of the relative cheapness of pork. 'Admitting occasional exceptions,' he observes, 'the hooked worm infests the poor, and the hookless worm the rich. This circumstance

accords with the fact, that the lower classes subsist chiefly upon pork, whilst the wealthier prefer mutton, veal, and roast-beef.'—*Entozoa*, p. 243. It gives rise to the same symptoms as the *T. solium*.

The next five tapeworms infesting man may be passed over without notice, as being of very rare occurrence. *Tænia acanthotrias* is only known from a single case, in which, in the larval stage, it was found in the muscles of a woman. The last species we shall describe, the *T. echinococcus*, is, in its larval condition, probably more fatally injurious to the human race than all the other species of entozoa put together. In its mature (strobila) condition, in which it is found only in the dog and wolf, it seldom exceeds the fourth of an inch in length, and develops only four segments, including that of the head. The final segment, when sexually mature, equals in length the three anterior ones, and contains as many as 5000 eggs. The proscolex or embryo forms large proliferous vesicles, in which the scolices or larvæ (known also as acephalocysts, echinococci, echinococcus heads or vesicles, pill-box hydatids, &c.) are developed by gemmation internally. The eggs develop in their interior a six-hooked embryo, and these embryos are introduced into our bodies with food or water into which the eggs have been carried. 'With an especial liking for the liver,' says Dr Cobbold, 'they bore their way into this organ, or are carried along the circulating current to other organs. In these situations, they sooner or later become transformed into simple vesicular, bladder-like bodies, commonly called acephalocysts or hydatids.' Instead, however, of displaying the head, neck, and body of a cysticercus, the vesicle retains a globular figure. Its growth is slow, and many months elapse before echinococci are developed within our bodies, after we have swallowed the proper T. eggs and their contained embryos. There have been great differences of opinion amongst physiologists as to the mode of development of these echinococci; but the following is probably the current view. The inner surface of the vesicle presents after a time slight papillæ or prominences, which, as they enlarge and become oval, are eventually scoleciform, and contain a cavity filled with a limpid fluid. This scolex-like development produces in its interior a brood of scolices or echinococcus heads, or, in other words, becomes gradually transformed into the so-called 'brood-capsules' of helminthologists. It is almost impossible to explain the nature of these brood-capsules, with young echinococci in their interior, without the aid of such diagrams and illustrations as are given by Cobbold in his chapter on *T. echinococcus*. In the fully developed state, the echinococci vary from $\frac{1}{80}$th to $\frac{1}{100}$th of an inch in diameter. The rostellum supports a double curve of hooks, those in the smaller row varying in size from $\frac{1}{1040}$th to $\frac{1}{1780}$th of an inch, whilst those of the larger series are from $\frac{1}{830}$th to $\frac{1}{1780}$th of an inch. Below the hooks are four suckers, and the general appearance of the body is finely granulated, from its containing calcareous particles. These hooklets are so characteristic and important in diagnosis, that we give a highly magnified representation of them. It often happens that the discovery under the microscope of a few of these little hooks at once decides the nature of an otherwise mysterious tumour. Of 373 cases of the parasite occurring in man, collected by Davaine (who devotes more than one-third of his *Traité des Entozoaires* to this subject), 165 affected the liver, 40 the lungs, 30 the kidneys, 20 the brain, and 17 the bones, while the remainder were spread over other parts; and of 136 cases collected by Cobbold, 51 affected the liver. No less than 35 of these 51 cases recovered. 'Four of them were complete natural cases; two others being also temporarily cured in the same way. All the rest were cured by surgical operations.' It is impossible to state with accuracy the degree or prevalence of hydatids in Great Britain, or the extent to which it proves fatal. In Iceland, this disease is endemic to such a degree that about one-sixth of the population are affected with it. It produces a long illness, terminating with a painful death, and no means of cure have yet been discovered. Its prevalence in that island may be rationally accounted for. Firstly, every peasant has, on an average, six dogs, all of which are probably infested by the mature T.; and secondly, there being only six legally authorised medical men, the great majority of the population (over 10,000 persons, scattered over 1500 sq. m.) are in the hands of quacks, whose principal treatment consists in the administration of *fresh dog-excrement!*

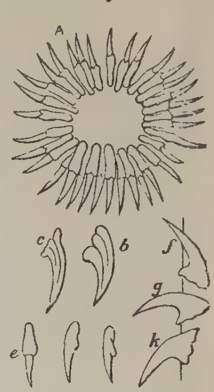

Fig. 5.

A, magnified view of the circle of hooklets, seen upon its under surface, thirty-four in number; *b*, *c*, lateral views of the separate hooklets; *e*, hooklets seen on the inferior or concave border; *f*, *g*, *h* illustrates the movements and position of the hooklets, the vertical line running through the fixed point of each of the three hooks.

Our authority for this astounding specimen of homœopathic treatment is Leuckart, whose admirable popular essay, *On the Newest Discoveries regarding Human Intestinal Worms, and their Importance in Relation to Hygiene*, in the *Conversations Jahrbuch*, 1863, is deserving of the most careful study. For an excellent abstract of the remarkable series of experiments—extending from 1851 to the present day—by which the relationship between the so-called cystic worms and the cestoid worms was established, we may refer the reader to Aitken's *Science and Practice of Medicine*, vol. i.; while for the subject of T. generally, the highest authorities are the works of Küchenmeister and Siebold, translated by the Sydenham Society; Davaine's *Traité des Entozoaires;* Weinland's *Essay on the Tapeworms of Man;* Leuckart's *Das Menschlichen Parasiten* (not yet completed); and Cobbold's *Entozoa*, 1864, a work equally remarkable for the vast amount of original research which it contains, and for the beauty and correctness of the illustrations.

TAPEWORMS, although rare amongst horses and cattle, are common in dogs and sheep, causing irritability of the bowels, and an unthrifty appearance. For dogs, no remedy answers so well as powdered areca nut, of which 30 grains suffice for a dog weighing about 20 lbs. It is best given after ten or twelve hours' fasting, in a little soup or milk, and should be followed in a few hours by a dose of castor oil. Neither areca nut nor any of the approved remedies used in men, prove effectual in sheep; and one of the best prescriptions for them consists of 40 drops of oil of turpentine, a drachm of powdered green vitriol, and an ounce of common salt, given mixed in a little milk or gruel, or, where their bowels are confined, in linseed oil. A daily allowance of linseed cake and sound dry food should likewise be given with the grass or roots, and pieces of rock-salt left within the animal's reach.

TAPIO'CA. See MANIOC and CASSAVA.

TA'PIR (*Tapirus*), a genus of the *Perissodactyle* division of the *Ungulata;* having a bulky form, with moderately long legs; the fore-feet four-toed, the hind-feet three-toed; the skin thick, the hair short; the tail very small; the neck thick; the ears short; the eyes small; the muzzle elongated; the nose prolonged into a short, flexible proboscis, which, however, does not terminate in an organ of touch and prehension, like that of the elephant; six incisors, two canine teeth, and fourteen molars in each jaw, the molars separated from the canine teeth by a wide interval. The best known species is the AMERICAN T. (*T. Americanus*), which is about the size of a small ass, and is common in almost all parts of South America, its range extending as far south as the Strait of Magellan, although it suddenly ceases to be found at the Isthmus of Darien. Its colour is a uniform deep brown, but the young are beautifully marked with yellowish fawn-coloured stripes and spots. The skin of the neck forms a thick rounded crest on the nape, with a short mane

Malayan Tapir (*Tapirus Malayanus*), and Young.

of stiff hair. The T. inhabits deep recesses of the forest, and delights in plunging and swimming in water. It feeds chiefly on young shoots of trees, fruits, and other vegetable substances; but is ready to swallow almost anything that comes in its way. Pieces of wood, clay, and pebbles are often found in its stomach. It sometimes commits great ravages in cultivated grounds; a large herd of tapirs sallying forth from the forest by night, trampling and devouring all that they find in the fields. The T. is a very powerful animal, and, protected by its thick hide, forces its way through the forest where almost no other quadruped can. When assailed by the jaguar, it seeks to get rid of him by rushing through thick underwood, and if it can reach water, is often successful by plunging in and diving. It is inoffensive, never attacking man; but when hard pressed by dogs, makes a violent resistance, and inflicts severe bites. It is very easily tamed, and becomes extremely familiar; but its large size makes it a troublesome pet. Its hide is useful, and its flesh is eaten, although rather dry.—The MALAYAN T. (*T. Malayanus* or *Indicus*) is found in Malacca, Sumatra, &c. It is larger than the American T., and its proboscis is rather longer in proportion. The neck has no mane. The colour is glossy black, except the back, rump, and sides of the belly, which are white. The colours do not pass gradually one into another, but the line of separation is marked, giving the animal a very peculiar appearance. The habits of this species are very similar to those of the American T., and it is equally capable of domestication. The young are striped and spotted as in that species.—A third species is found in the mountainous parts of South America, and two in Central America and Mexico.

The remains of tapirs have been found in Miocene and subsequent strata. In all, about twelve species have been determined. Tapir-like animals are common in Eocene beds. Ten species of *Palæotherium* (q. v.) have been described. *Lophiodon*, of which fifteen species have been observed, differs from *Palæotherium* in the structure of the teeth of the lower jaw —and from other peculiarities in the same organs, *Coryphodon* (containing three species) has been separated from both genera.

The T. is a remarkable exception to the generalisation deduced from the comparison of the later Tertiary mammals with those living in the same districts at the present day, viz., that there is a close correspondence between the fauna of the two periods. The Pliocene and Post-pliocene bears, hyenas, tigers, elephants, &c., of Europe and Asia are represented by living species of the same of nearly allied genera. The recent sloths, armadilloes, and prehensile-tailed monkeys of South America were preceded by closely related forms in the later Tertiary period; as were also the marsupials of Australia. Several species of T. have been found in Europe, but they have left no representatives nearer than Eastern Asia and South America.

TAPPING is an operation which is most commonly performed on the abdomen, but occasionally on the chest and head. Tapping of the abdomen gives great relief when the abdomen becomes inconveniently distended with fluid contained in the peritoneal sac, or, in the case of the female, in an ovarian cyst. A small incision is then made about two inches below the navel, through which the cutting surfaces of the trochar—the instrument used in this operation—are passed. By arrangements into which we need not enter, the fluid escapes through this instrument. The wound made by the trochar in the abdomen will, in ordinary cases, heal in a few days.

Tapping of the chest is an operation which is occasionally required for the relief of empyema and other effusions in the cavity of the pleura. Tapping of the head has been occasionally found successful in hydrocephalus. Tapping of the pericardium has been practised in cases of pericardial dropsy, but it is an operation not to be recommended under any circumstances.

TA'PTI, a river of the British presidency of Bombay, India, rises in the Saugur and Nerbuddah territories, in lat. about 21° 46′ N., flows west through Scindhia's dominions and the districts of Candeish and Surat to its mouth in the Gulf of Cambay, 17 miles below the town of Surat. It is 441 miles in length; but can hardly be said to be navigable, for even small vessels of from 40 to 50 tons burden cannot ascend higher than Surat.

TAR is a well-known substance, for which it is difficult to frame a definition, since it varies in composition, colour, and consistence, and is derived from all three kingdoms of nature. In various parts of the world, it occurs as a natural mineral product, and is known under the various names of bitumen, asphalt, petroleum, natural tar. See NAPHTHA. As an animal product, a species of tar is obtained from the destructive distillation of bones employed in preparing bone-black. The distillate, which possesses a most offensive odour, separates into a heavier layer of black animal tar—commonly known as *bone-oil*, or *Dippel's Animal Oil*—and a lighter layer of watery solution of sesquicarbonate of ammonia, commonly known as *bone-liquor*, and much employed in the preparation of various salts

of ammonia. This animal tar is chiefly used for the lubrication of machinery. The vegetable kingdom is, however, the most important source of tar. On submitting wood to destructive distillation in closed vessels, we obtain a large number of products, which are described in the article WOOD, DISTILLATION OF; some are gaseous and some liquid, and of the latter one portion is soluble and the other insoluble in water. This insoluble portion constitutes wood-tar, and is composed of a mixture of various liquids holding solid matters in solution or in suspension. Amongst its most important constituents, Professor Miller mentions several forms of hydrocarbon, such as toluol, $C_{14}H_8$; xylol, $C_{16}H_{10}$; cymol, $C_{20}H_{14}$; and eupion, besides a number of oxidised compounds, including creasote, $C_{24}H_{16}O_4$, picamar, and kapnomar, $C_{20}H_{11}O_2$; whilst among the solid portions are resinous matters resembling colophony, and a waxy substance named paraffin, and many other substances, such as naphthalin, cedriret, pittacal, pyrene, $C_{30}H_{12}$; chrysene, $C_{12}H_4$; and pyroxanthin. (When the formula is not given, the exact composition of the substance is not determined with certainty.) The *Stockholm tar*, which is so widely used in ship-building, and the *American tar*, which is almost equally celebrated, are chiefly prepared from the resinous wood of the pine, and especially of the root of the tree. The specific gravity of ordinary tar is about 1·040. Peat yields a tar very similar to wood-tar. Coal yields, on distillation in closed vessels, even a larger number of products of distillation than are yielded by wood. In addition to numerous gaseous products, the liquid portions contain water and various forms of hydrocarbon, which collectively form the liquid known as *coal-naphtha;* besides which there is a large quantity of a dark viscous matter known as *coal-tar.* The mixture of naphtha and tar is described in this work under the title of GAS-TAR. The distillation of coal-tar is conducted on an extensive scale as a separate branch of trade. For a description of the operation, we must refer to Professor Miller's *Organic Chemistry* (2d ed., pp. 650, 651), from which work we extract the following remarks on the compounds present in this substance: 'Of the substances contained in coal-tar, some are basic, and some acid, but the principal portion consists of neutral or indifferent bodies. The bases include ammonia, aniline, picoline, quinoline, and pyridine. Among the acids, the acetic is present in small amount; but the most important is phenic acid, the carbolic acid of Runge. This chemist also mentions two other acids named *rosolic* and *brunolic* acids. The neutral substances contain several hydrocarbons, including benzol, toluol, cumol, and cymol, which are among the liquid constituents; while naphthalin, anthracene, chrysene, and pyrene are amongst those which are solid at ordinary temperatures.' When either wood-tar or coal-tar is submitted to distillation, the solid brown or black residue left in the retort constitutes *pitch.*

Wood-tar, under the title of *Pix liquida*, is included in the Pharmacopœia, in which its characters are given as follow: 'Thick, viscid, brownish black, of a well-known peculiar aromatic odour. Water agitated with it acquires a pale-brown colour, sharp empyreumatic taste, and acid reaction.' Tar was more used in medicine in former times than at present. Bishop Berkeley's commendatory essay on the use of tar-water in diseases of the chest and kidneys, is well known to all literary students (see Chambers's *Book of Days*, vol. i. p. 108). Since his time the inhalation of tar-vapour has been highly recommended in cases of phthisis; and tar-capsules are still occasionally prescribed in cases of relaxed mucous membrane. In the present day, tar is, however, seldom used except as a local stimulant in chronic cutaneous diseases.

In modern commerce, there are two kinds of wood-tar known—that made in the north of Europe from the wood of *Pinus sylvestris*, and the North American, which is made from *Pinus rigida*, *P. tæda*, *P. Australis*, &c. The distillation is usually performed in a very rude manner: a funnel-shaped hole is dug in a bank, about 6 or 8 feet in diameter at the upper part, and not more than 18 inches at the lower. At the bottom of the hole is placed an iron pan, having a long spout or pipe, which is made to pass through the bank; the hole is then filled up with billets cut from the roots and branches of the pine-trees, which, after being kindled at the top, are covered over incompletely with turf. The wood is thus charred from above downwards; and the tar, mixed with various other products, flows off at the bottom through the spout into a receiver. A somewhat similar product is obtained in the distillation of coal for gas, and in the distillation of bones in forming animal charcoal. Formerly, the chief value of these materials was as a preservative coating for exposed wood-work, ships' sails, ropes, &c., in consequence of their very highly antiseptic properties. A better knowledge of their chemical history has, however, much increased their value. The imports of wood-tar into Great Britain exceed five millions of gallons, besides which, nearly two millions more are made from coal and bones in gas and charcoal works. The total value of this product amounts to upwards of £400,000 per annum.

TA'RA, or **TARO** (*Colocasia macrorhiza*), a plant of the natural order *Araceæ*, of the same genus with the Cocco (q. v.), or Eddoes, and cultivated for its roots, which are a principal article of food in the South Sea Islands. The roots are 12 to 16 inches long, and as much in girth. They are washed to take away their acridity, which is such as to cause excoriation of the mouth and palate. They are cooked in the same way as bread-fruit, the rind being first scraped off. A pleasant flour is made of tara. Many varieties are cultivated. The plant has no stalk; broad, heart-shaped leaves spring from the root; and the flower is produced in a spathe. The leaves are used as spinach.

TARA FERN (*Pteris esculenta*), a species of Brake (q. v.), the root (rhizome) of which was one of the principal articles of food of the New Zealanders, before the settlement of New Zealand by British colonists. This fern comes to perfection only in good soils, and there the plant is 10 feet high. Plants three years old furnish the best roots, which are about an inch in circumference. The root, being dug up, is cut in pieces about 9 inches long, and placed in stacks, carefully protected from rain, but through which a current of air blows. Fresh fern-root is not good; it is the better of being a year above ground. Before being cooked, it is steeped in water, and dried in the sun. It is then roasted. A large quantity of a very pleasant flour is obtained from it by beating on a stone, the fibre alone being thus left.

TARA'NNON SHALE, the upper member of the Llandovery formation of the Silurian Rocks (q. v.). It consists of shales, or pale, sometimes purple, slates with very few fossils.

TA'RANTISM may be defined a leaping or dancing mania, originating in, or supposed to originate in, an animal poison. The name is supposed to be derived from the ground-spider, *Tarantula* (q. v.), which conveyed the poison into the human body by its bite. The gesticulations, contortions, and cries somewhat resembled those observed in St

Vitus's Dance, and other epidemic nervous diseases of the middle ages, with which tarantism was contemporaneous; but the affection differed from these in its origin, in the cachexia present, in the elegance of the movements of the victims, in their partiality for red colours, bright and luminous surfaces, their passion for music, and in their restoration depending upon the use of instrumental or vocal music as a remedy. Although the sufferers were subjected to extraordinary treatment, such as being buried up to the neck in earth, the success of music was so universal and invariable, that a class of tunes and songs was composed, called *Tarentella*, to be employed in the cure of the tarantati. These have lingered long after the extinction of the malady, and may still be heard in the wilder districts of Italy. While it is highly probable that the physical symptoms were due to the bite of spiders, the mental disturbances and muscular *agitation* should be traced to the secondary effects of these upon the nervous system and imagination. It appeared in various parts of Italy, but was most prevalent in Apulia, where the insects abound. No age or class appears to have been exempt, for we read of a philosophic bishop who allowed himself to be bitten by a tarantula, dancing, &c. as fast and furiously as the peasantry.—Hecker, *Epidemics of Middle Ages*, p. 110; Madden, *Phantasmata, or Illusions and Fanaticisms*, vol. i. p. 415; Milligen, *Curiosities of Medical Experience*, p. 88.

TARA'NTO (anc. *Tarentum*), a town of Southern Italy, province of Terra d'Otranto, is situated on a rocky islet, formerly an isthmus, between the Mare Piccolo (Little Sea), an extensive harbour on the east or landward side of the town, and the Mare Grande (Great Sea), or Gulf of Taranto, on the west. The natural channel between the two 'seas' has been spanned by a long bridge of seven arches, rendering the Mare Piccolo quite useless as a harbour, and forcing ships to anchor in the outer roads, which are much exposed to south and south-west winds. The principal buildings of T. are a cathedral dedicated to St Cataldo, a native of Raphoe in Ireland, who was first Bishop of T.; a fine episcopal palace; a castle and fortifications erected by Charles V., and commanding both seas; and two hospitals. The streets are as narrow and dark as those of an oriental city. T. has manufactures of velvets, linens, and cottons, but little commerce. The Mare Piccolo, however, is still famous (as of yore) for its immense abundance of shell-fish, and a considerable portion of the population (which amounts to about 30,000) derives its subsistence from the oyster and mussel fisheries.

Ancient Tarentum, however, was a far more famous and splendid city than its modern representative. Founded by a body of Spartan emigrants about 708 B. C., it grew and prospered for centuries in happy obscurity. Its territory was not perhaps very fertile, but its pasturage was of the finest, and its olive groves were unsurpassed. Yet it was not these things that ultimately made it the sovereign city of Magna Græcia; this rank it attained through the supreme excellence of its harbour (the Mare Piccolo), ample and secure beyond all the other harbours of Lower Italy. Gradually it became the chief emporium of the Græco-Italian trade, and long after all the rest of the colonial cities in Magna Græcia had fallen into decay, Tarentum was 'blooming alone' in undiminished prosperity. We may pass over its earlier history, noticing only the fact, that in the 4th c. B. C., it had for its *strategos*, or general (seven times), the philosopher and geometer Archytas, under whom it became the headquarters of the Pythagorean sect, and was honoured with a visit from Plato, who was the guest of Archytas during his residence there. But while in the very acmé of its greatness, it provoked a quarrel with Rome (q. v.), 281 B. C., in which, though aided by the gallantry of Pyrrhus (q. v.), king of Epirus, it was utterly crushed, after a struggle of less than ten years; and though its natural advantages hindered it from sinking into such absolute insignificance as other cities of Magna Græcia, it was never after a place of great importance. Under the Empire, it was quite overshadowed by Brundusium on the Adriatic, but rose again during the Gothic wars, and passed into the hands of the Saracens and Greeks, from the latter of whom it was wrested by Robert Guiscard, the Norman, in 1063. Since then, it has shared the fortunes of the kingdom of Naples. Few relics of the classic Tarentum are extant, the chief being bits of an amphitheatre, a circus, and traces of some of the temples.

TARA'NTULA (*Lycosa tarantula*), a species of spider, of a genus to which the name Wolf-spider is often given, a native of the south of Europe. It derives its name from the city of Taranto, in Italy, where it is very plentiful. It is one of the largest of

Tarantula Spider (*Lycosa tarantula*).

European spiders, of a somewhat elongated shape, with rather long legs. It is one of those spiders which seek their prey by hunting. Its bite is much dreaded, and has been supposed to cause the disease called *Tarantism* (q. v.).—Several species of spider nearly allied to the T. are found in different parts of the south of Europe. One of them (*Lycosa Narbonnensis*) frequents dry uncultivated grounds in the south of France, and makes a little pit in the ground, near the entrance of which it sits watching for prey. The prey is carried into the pit to be devoured. The female shews great affection for her young.

TARARE, a thriving and important manufacturing town of France, in the dep. of Rhone, stands at the foot of Mount Tarare, one of the highest summits of the Beaujolais range, 21 miles north-west of Lyon. Formerly unimportant, it is now a rich and flourishing town, the inhabitants of which are engaged in the manufacture of muslins, cloth, silk, and merino fabrics, and in embroidering and bleaching. The muslins of T. are famous for their fineness. See TARLATAN. Pop. 14,569.

TARASCON, a town of France, in the dep. of Bouches-du-Rhone, 13 miles south-west of Avignon by railway. The church of St Martha dates from the year 1187, and is so called after Martha, the sister of Lazarus, and the patron saint of the town. Woollen and silk fabrics, and brandy and vinegar, are manufactured. Pop. 13,489.

TARA'XACUM, or Dandelion (q. v.) Root, is employed to a considerable extent in medicine. The roots should be gathered in August and September, when the juice is most abundant. There is no very satisfactory analysis of this juice, but it is said to contain mannite, resin, sugar, gum,

caoutchouc, and a crystallisable matter termed *taraxicine*, on which its active properties probably depend. This medicine may be prescribed with advantage in the form of extract, decoction, or juice in chronic diseases of the liver, and in certain forms of dyspepsia and skin-disease which are accompanied by derangement of the biliary organs. In very large doses, it has a diuretic and slightly aperient action.

TARAZO'NA, a town of Spain, in the province of Zaragoza, 52 miles west-north-west of the city of that name, on the Queyles, a tributary of the Ebro. It stands on a wind-blown plain, exposed to bleak winds from the Sierra de Moncayo on the south and from the Pyrenees on the north. It is the see of a bishop; and contains a cathedral with a slender brick spire and rich interior, a bishop's palace, and a Moorish *Alcazar*. Pop. upwards of 6000, mainly engaged in agriculture.

T. is the ancient *Turiaso;* and here a few Roman troops routed a Celtiberian army. It became a municipium under the Romans; and under the Goths, by whom it was fostered, it became famous for its steel.

TARBAGATAI', a frontier town of Chinese Turkestan, 170 miles east of the eastern extremity of Lake Balkash, in lat. 46° 44′ N., long. 82° 28′ E. It stands at the foot of the mountains of the same name, in a plain watered by the Imil, and with extensive meadows and pasture-grounds in the vicinity. The inhabitants consist of 3000 exiled Chinese, 1000 of a Chinese garrison, and a number of Mongolian merchants. The trade with Russia is important.

TARBES, a town in the south of France, capital of the dep. of Hautes-Pyrénées, stands on the left bank of the Adour, 23 miles east-south-east of Pau. It is a station on the *Chemin de fer du Midi*, and the centre of communication with all parts of the Pyrenees, the lofty line of which bounds the prospect on the south. The modern cathedral is the principal and indeed the only notable building. There is here a *haras*, or government stud, for the improvement of the breed of horses. T. is the seat of an active general trade. Pop. 14,768.

T. dates from the time of the Romans, and its bishopric was founded in the year 420.

TARDIGRADA. See SLOTH.

TARE (*Ervum*), a genus of plants of the natural order *Leguminosæ*, sub-order *Papilionaceæ*, distinguished from *Vicia* (see VETCH), to which it is nearly allied, by a capitate stigma, downy all over. It contains only a few species of weak climbing plants, natives of the temperate parts of the Eastern Hemisphere. One of these is the LENTIL (q. v.).—Two (*E. hirsutum* and *E. tetraspermum*), generally known by the name of TARE, are common in cornfields and hedges in Britain. They have very small flowers and pods; the leaves are pinnate, and the leaflets small. They afford nourishing food for cattle, but the quantity is so small that they are not worthy of cultivation, and are chiefly known as a nuisance in cornfields. A species of T. (*E. sativum*), with an upright branching habit, is cultivated in some parts of Europe for its herbage, which is used for feeding cattle. The bulk of herbage is small, but its nutritious character is thought to compensate for this. The leaves have from 8 to 14 pair of leaflets. The plant thrives well in poor sandy soils.—It is not supposed that the *Tare* of the New Testament has any affinity to these plants: it is doubtful what it is, but it appears not improbable that it is the DARNEL (q. v.).

TARE AND TRET, certain deductions usually made from the gross weight of goods. *Tare* is the weight of the box, cask, bag, or wrapping in which the goods are contained; and the amount is obtained either by weighing the empty package itself, by taking an average of a few similar packages of equal size, or by mutually agreeing upon a certain proportion of the gross weight. The remainder, after deducting the tare, is the *net weight*. Another deduction, at the rate of 4 lbs. for every 104 lbs., or $\frac{1}{26}$th of the net weight, is then made, as an allowance for waste through dust, &c., and is called *tret*. Some other allowances of minute magnitude as draft, cloff, &c., are occasionally made after tret, but they are falling into disuse.

TA'RGET (root uncertain, but the word, in some form, found in all European languages), in its modern sense, is the mark for aiming at in practising with the cannon, rifle, or bow and arrow. In its more ancient meaning, a target or targe was a shield, circular in form, cut out of ox-hide, mounted on light but strong wood, and strengthened by bosses, spikes, &c. Of modern targets, the simplest is that used for Archery (q. v.). With regard to rifle targets, the spread of the Volunteer movement and the numerous rifle-matches have caused ranges to be constructed over the whole country. The necessities are: a butt, artificially constructed or cut in the face of a hill, to prevent wide balls from scattering—a marker's shot-proof cell, near the targets—and a range of such length as can be procured.

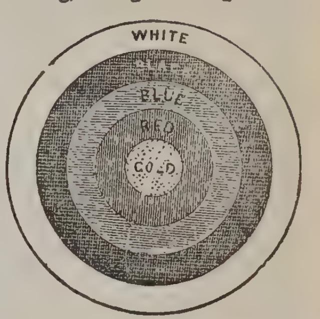

Fig. 1.—Archery Target.

The sizes of targets used by the British army are as follows: for firing up to 300 yards, the target is 6 feet high by 4 feet broad, with a bull's-eye 2 feet high by 1 foot broad; centre, 4 feet high by 2 feet broad. Up to 600 yards, the target is 6 square feet, bull's-eye, 2 square feet; centre, 4 square feet. Up to 800 yards, the target is 6 feet by 8; bull's-eye, 2 feet high, 3 feet broad; centre, 4 feet high, 6 feet broad. The marker signals the 'hits' from his box, denoting a bull's-eye by a red-and-white flag, a centre by a blue flag, and an outer by a white flag. If he shew a red flag, it is to cease firing while he inspects the target. In scoring, the outer counts 2; centre, 3; and bull's-eye, 4. A red flag should fly on the butt during the whole time of practice, to warn passers-by to keep off the range. Some of the targets used by the National Rifle Association at Wimbledon are different from those used by the army. The bull's-eye of the target used up to 300 yards is 8 inches square; centre, 2 feet square. The target up to 600 yards is the same

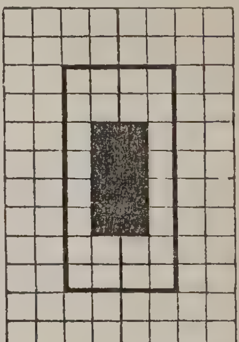

Fig. 2.
Target for distances up to 300 yards.

as in the army. For distances up to 1100 yards, the target is 6 feet high by 12 feet broad; bull's-eye, 3 square feet; centre, 6 square feet. The

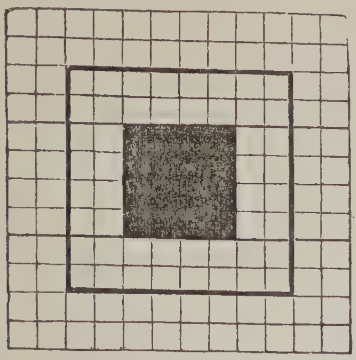

Fig. 3.—Target for distances up to 600 yards.

system of signalling is that invented by Captain Hill of Brentwood, Essex. The mantelet, or butt for the marker, is placed close up to one side of the target, a little in front; the marker is protected from the splash of the bullet by a shield, he having

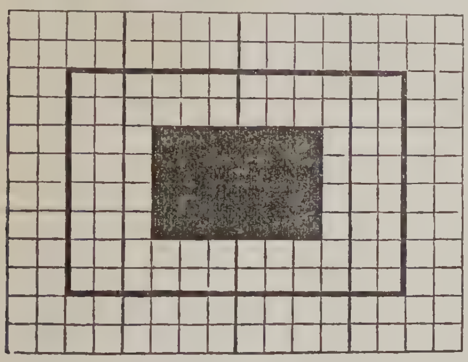

Fig. 4.—Target for distances up to 900 yards.

a full view of the target through a small pane of thick glass, wiping out each shot-mark, through a slit in the shield, with a brush placed on the end of a pole; at the same time, the value of the shot is shewn by a coloured disc attached to the pole.

Various descriptions of targets have been made by which the value of the shooting is denoted by electric apparatus, or by signals worked by machinery placed behind the target. In artillery practice, targets of considerable size are used at long ranges. The usual practice is over the sea; targets are then painted on the sides of old vessels, or are floated by buoys. For trying the power of ordnance, solid targets are constructed to resemble the sides of iron-plated ships, portions of fortification, &c.

TARGOWI'TZ, or TARGOWICZA, in Russia, a small town in the government of Kiev (q. v.), on the borders of Kherson, was the scene (May 1792) of a confederation ('plot' as the patriots had it) of the five Polish nobles (Potocki, Branecki, Bzeureski, and two others of little note) who were adverse to the constitution of 3d May 1791. They were incited to this traitorous conduct towards their country by Catharine II., and after their conduct had been fully unveiled, they were declared traitors to their country, and only escaped death by precipitate flight to Russia, where they were munificently rewarded for the treason which had given the czarina a pretext for executing the second partition of Poland (q. v.).

TA'RGUM (Chaldee, from *tirgem*, a word of uncertain origin, designating to translate, explain), the general term for the Aramaic Versions of the Old Testament, which became necessary when after, and perhaps during the Babylonian Exile, Hebrew began to die out as the popular language, and was supplanted by 'Chaldee,' an idiom, or rather a family of idioms, on which we have spoken under SHEMITIC LANGUAGES.

The origin of the Targum itself is shrouded in mystery. The first signs of it—as an already fixed institution—have been found by some in the book of Nehemiah, and according to tradition, Ezra and his coadjutors were its original founders. However this be, there can be no doubt that its beginnings belong to a comparatively early period. The Mishna (q. v.) contains a number of strict injunctions respecting it, and also respecting a certain guild of Meturgemans (whence dragoman) or interpreters, who had sprung up as professional followers of those learned men who, at a previous period, had volunteered their services in the translation and paraphrastic interpretation, both activities, as we said, implied by the term. At first, and indeed for many centuries, the Targum was not committed to writing, for the same reason that the 'Oral Law' itself was not at first intended ever to become fixed as a code for all times. In the course of time, however, both had to yield to circumstances, and their being written down, was considered preferable to their being utterly forgotten, of which there was no small danger. Yet a small portion only of the immense mass of oral Targums that must have been produced, has survived. All that is now extant are three distinct Targums on the Pentateuch, a Targum on the Prophets, Targums on the Hagiographa, viz., on Psalms, Job, Proverbs, the five 'Megilloth' (Song of Songs, Ruth, Lamentations, Esther, Ecclesiastes), two Targums on Esther, one on Chronicles, one on Daniel, and one on the apocryphal pieces of Esther. The most important of the three Pentateuch Targums is the one named after Onkelos (q. v.), probably a corruption of Akylas, whose Greek version had become so popular that this Chaldee version was honoured with being called after it. In its present shape, this translation dates probably from the end of the 3d or beginning of the 4th c. A.D., although snatches of it were collected and written down more than a hundred years earlier. We have spoken of its language and its general character already under ONKELOS, and may here briefly state that it is composed in an Aramaic closely resembling that of Daniel, and that it is as excellent a translation 'for the people,' which it meant to be, as can well be conceived. Occasionally, when the subject imperatively demands it, it introduces some paraphrastic by-work, and it only deviates from the text where the divine dignity would have appeared to suffer in the eyes of the multitude by a literal interpretation. Its value for exegetical purposes is no less great than it would be for linguistic and antiquarian purposes, were it more explored with that view than has been the case as yet.

The two other Targums on the Pentateuch, hitherto known as Targum Jonathan ben Uzziel, and Targum Jerushalmi, are merely recensions of one and the same version—the name of the first recension being merely a perpetuated error of a single scribe—which owes its origin to Palestine or Syria (Onkelos being of Babylonian origin), and cannot well have been redacted before the 7th c. A.D. There is no doubt that originally this 'Jerusalem Targum' embraced

the whole of the Old Testament, as did the Babylonian; but nothing has survived beyond these two recensions of the Pentateuch, the first complete, the second in a fragmentary condition: the former probably intended as an emendation of Onkelos, chiefly in the direction of homiletic paraphrase and legendary lore, and the latter as a further emended emendation of single portions. As a version, this Targum is of small importance; but it is invaluable as a storehouse of allegories, parables, sagas, and the like popular poetry of its time. Its language and grammar are exceedingly corrupt; it abounds, moreover, with foreign—Greek, Latin, Persian, and Arabic—terms; and its general use lies more in the direction of Jewish literature itself, as well as of archæology and antiquities of the early Christian centuries, than in that of a direct interpretation of the Bible text itself. The Targum on the Prophets is generally and erroneously ascribed to Jonathan ben Uzziel, an eminent master of the law at the time of Hillel the Elder; the fact being that, except one spurious Talmudical passage, in which mention is made of his having translated the Prophets, this Targum is everywhere else, from the Talmud down to the authorities of the 10th c. A.D., ascribed to one R. Joseph, president of a Babylonian academy in the 4th century. And it would indeed seem as if this statement were completely in accordance with the real facts—if not the writing, but the collection and final redaction of this Targum is ascribed to him. Respecting the nature of this version, it may be said that, while being tolerably literal in the first—historical—books, it gradually becomes a mere framework of Midrash (q. v.) or Haggada, which it introduces at every turn and at great lengths. It further contains historical bits, disguised, or rather typified, and some lyrical pieces of rare poetical value. In language and general manner, it resembles Onkelos, with which it is of one growth, place, and date, and of which it forms only a kind of continuation.

To the same Joseph 'the Blind' to whom the redaction of the foregoing Targum is probably due, is further ascribed a Targum on the Hagiographa. But between him and the Hagiographical Targums lie, at the least, 600 years; their date being approximately given as about 1000 A.D. Certain distinctions between the different books must further be made. The Targums on Psalms, Job, and Proverbs were probably contemporaneous compositions due to Syria. The two former are made more paraphrastic than the last, which resembles closely the Syriac version. The paraphrase on the five 'Megilloth'—a very late production indeed—is principally a collection of more or less poetical fancies, traditions, and legends, to which the single verse in hand merely seems to furnish the key-note. There is, we need not add, but very little to be found in them of what originally must have formed the Targum on these books; nor is there the slightest hint to be found as to who was the real author or editor of their present form. That it was one man's work, is probable enough, from a certain unity of design and style noticeable in all of them. Their dialect lies somewhat between the East and West Aramaic. The Targum on the Book of Chronicles—almost unknown until the 17th c.—also belongs to a late period, and was probably composed in Palestine. There are some useful philological, historical, and chiefly geographical hints to be gleaned from it, but nothing more; least of all can it be used exegetically. A Persian version of a Targum on Daniel (unedited) is all that has been discovered on that book as yet. It was probably composed in the 12th c., the influence of the early Crusades being plainly visible in it. On the paraphrase of the apocryphal pieces of Esther, we shall not dwell here, any more than on the scanty fragments of a 'Palestinian Targum' that are found either interspersed in the general (Babylonian) Targum, or as independent pieces. It seems probable that more of this Palestinian version will come to light some day, as authorities of a few centuries back still quote from it rather largely. At present, however, their quotations are nearly all that remains.

Very little—we might say, next to nothing—has been done as yet to utilise this most important branch of Aramaic literature; in fact, not even an attempt at anything like a critical edition has been made, although it would be difficult to find a more corrupt text than that offered by the MSS. and single printed portions. Some parts have been done into Latin, English, German, &c. The ed. pr. of Onkelos is dated Bologna, 1482; that of the Targum on the Prophets, Leiria, 1494.

TARI'FA, a seaport town of Spain, 20 miles south-west of Gibraltar. It is the most southern town of Europe, is surrounded by tower-embattled walls, and communicates by a causeway with a small island, on which stand a fortress and lighthouse. The town is the most thoroughly Moorish in Andalucia; it is quadrangular in shape, and its streets are narrow and dark. Tunny and anchovy fisheries are actively carried on. Pop. 8100.

T., the Carthaginian *Josa*, and the Roman *Julia Traducta*, received its present name from the Moors, who are said to have called it after Tarif (= Tarik ?) Ibn Malik, who landed there to reconnoitre previous to the conquest of the country. See MUZA; RODERIC. It was successfully defended in 1811 by 2500 troops (mostly British) against a French force of 10,000 men, under Victor and Laval.

TA'RIFF (from *Tarifa* (q. v.), where, during the rule of the Moors in Spain, duties were collected), a table or catalogue, generally drawn up in alphabetical order, of the duties, drawbacks, bounties, &c., charged or allowed on different kinds of merchandise, as settled by authority, or agreed to between different states. The principles of the tariffs of different countries depend on their respective commercial policy, and on the fluctuating interests and wants of the community. According to the presently existing British tariff, only 22 kinds of merchandise are subject to an import duty, and none to an export duty.

TA'RLATAN, a thin gauze-like fabric of cotton, used for ladies' ball-dresses, &c. It is usually dyed or printed in colours. Tarare, in France, is the chief centre of this manufacture, whence it is largely exported to Great Britain and other countries. Switzerland alone competes with France in the production of tarlatan, but those of the latter country far surpass the former in fineness.

TARN, a dep. in the south of France, bounded on the N. by the deps. of Aveyron and Tarn-et-Garonne, receives its name from the river Tarn. Area, 2216 sq. m.; pop. (1872) 352,718. The surface is in general elevated, and in the south and south-east are the Montagnes Noires and the Monts de l'Espinous, branches of the Cévennes. The rock of Montalet, the principal summit, is 4430 feet high. Wooded mountains, vine-clad hills, beautiful valleys, and fertile or grass-producing tracts, are the principal features of the landscape. The chief river is the Tarn, an affluent of the Garonne (q. v.), and which has a westward course of 200 miles. A fifth part of the surface is covered with forests, chiefly of oak and beech. The dep. is for the most part agricultural, and the most improved methods are in use. Eleven million gallons of wine are made in

average years. T. is divided into four arrondissements: Albi, Castres, Gaillac, and Lavaur. Albi is the capital.

TARN-ET-GARONNE, a small dep. in the south of France, bounded on the S.-E. by the dep. of Tarn. Area, 1435 sq. m.; pop. (1872) 221,610. The principal river is the Garonne, which flows north-west, and its affluents, the Tarn and Aveyron. The surface is marked by plateaux, about 1000 feet in average altitude; the highest hills do not rise above 1600 feet. The climate is beautiful, healthy, and temperate. Cereals are raised in great quantities. Of wine, 11,000,000 gallons are produced. The dep. is divided into the three arrondissements of Montauban, Castelsarrasin, and Moissac. Montauban is the capital.

TARNO'POL, a town of Austria, in Galicia, charmingly situated on the left bank of the Sered, 80 miles east-south-east of Lemberg. Agriculture employs the great mass of the inhabitants, and the horse-market held here periodically is the most important in Galicia. Horse-races also take place. Pop. 17,210.

TA'RNOW, a town of Austrian Galicia, near the right bank of the Dunajec, a navigable tributary of the Vistula, and 49 miles east of Cracow by the Vienna and Lemberg Railway. It is the seat of a Catholic bishop, contains a theological college, and a beautiful cathedral, in which are numerous monuments of marble, surmounted by statues, enriched with *bassi rilievi*, and rising to from 60 to 70 feet in height. Several industries are actively carried on, and there is a good general trade. Pop. (including suburbs) 16,400.

TARPAU'LIN, a large sheet of the coarsest kind of linen or hempen cloth, saturated with tar to render it waterproof. It is used for covering loaded wagons, the hatchways of ships, and similar things, as a temporary protection from wet.

TARPEI'AN ROCK (Lat. *Rupes Tarpeia*, or *Mons Tarpeius*), the name originally applied to the whole of the Capitoline Hill (see CAPITOL), but latterly confined to a portion of the southern part of the hill, the following being the legend commonly related in connection with it. In the time of Romulus, Tarpeia (a vestal virgin), the daughter of Sp. Tarpeius, governor of the Roman citadel on the Capitoline, covetous of the golden ornaments on the Sabine soldiery, and tempted by their offer to give her what they wore on their left arms, opened a gate of the fortress to the Sabine king, Titus Tatius, who had come to revenge the rape of the Sabine women. 'Keeping their promise to the ear,' the Sabines crushed Tarpeia to death beneath their shields, and she was buried in the part of the hill which bears her name. Subsequently, it was not unusual for persons condemned on the charge of aspiring to restore the monarchy, or of treason to the state generally, to be hurled from the T. R.—e. g., the famous Manlius, the saviour of the Capitol during the invasion of the Gauls.

TARQUI'NIUS, the family name of two kings of Rome, with whose history, or rather with the legends regarding whom, the fortunes of the city are closely interwoven. The story goes that Demaratus, a Corinthian noble, emigrated from Greece, and settled at Tarquinii, in Etruria, where he married an Etruscan wife, by whom he had two sons, Aruns and Lucumo. Aruns died during his father's lifetime, but Lucumo married into one of the noblest Etruscan families. His wife, named Tanaquil, was a bold, ambitious, and wise woman. By her advice, Lucumo resolved to go to Rome. He set out, accompanied by a large train of followers, and as he approached the Janiculum, an eagle swooped down, and snatching off his cap, carried it up to a great height, then descending, placed it on his head again. Tanaquil, who was deeply skilled in the science of augury, prophesied from this omen the highest honours for her husband, who was hospitably received at Rome, and soon after admitted to the rights of citizenship, whereupon he took the name of L. Tarquinius, or, according to Livy, L. Tarquinius Priscus. The Roman monarch, Ancus Marcius, appointed him guardian of his children; and on the death of the former, the senate and the citizens unanimously elected him to the vacant throne. His reign was a glorious one. Against the Latins, Sabines, and (according to Dionysius) the Etruscans, he waged successful war, forcing the whole of the twelve sovereign cities of Etruria to recognise his supremacy, and do him homage. But the works that he executed at home are even more renowned than his exploits abroad. To L. Tarquinius Priscus (*Priscus* is commonly translated the 'Elder;' but Niebuhr objects to this translation as involving an anachronism, and notices the fact that *Priscus* is a common cognomen among the Romans) are ascribed the construction of the magnificent *Cloacæ*, or sewers (see, however, CLOACA MAXIMA), which remain uninjured to this day; the laying out of the Circus Maximus and the Forum; the institution of the great or Roman games; and (some say) the building of the Capitoline temple (see CAPITOL). The legend also represents him as effecting certain political and sacerdotal changes. See ROME. T. was assassinated after a reign of 38 years, at the instigation of the sons of Ancus Marcius, who considered themselves as best entitled to the throne, and dreaded lest he should use his influence to get his favourite and son-in-law, Servius Tullius, chosen as his successor. But their crime did not avail them, for, through the dexterity of Tanaquil, Servius was elected to the vacant throne, and signalised himself not only by his military exploits, but also by great organic changes in the Roman constitution (see article ROME for an account of the 'Servian Reform'). T. left two sons, L. Tarquinius Superbus and Aruns, both of whom married daughters of Servius Tullius; and two daughters, one of whom married Servius Tullius himself and the other M. Brutus, by whom she became mother of L. Brutus, first consul of the Roman Republic.

L. TARQUINIUS SUPERBUS, son of the preceding, having murdered his father-in-law, Servius Tullius, at the instigation of his wife, is represented in the legend as audaciously usurping the vacant throne; but as the whole drift of his legislative policy was to abolish the reforms of Servius, there can be little doubt that the real significance of this part of his career lies in the fact, that it indicates a successful reaction, on the side of the patricians, against the more liberal and progressive policy of the preceding age. That the younger T., at least, is a historical character seems to be pretty generally allowed. The incidents of his career are so numerous and coherent, and the impress of his name and character is so deeply stamped on the national memory, that he cannot be regarded as a wholly imaginary personage. Analyse the story how we may, there will always remain a residuum of insoluble fact, not essentially at variance with the character of the tragic tradition. As far as we can gather from the ancient annals, the usurpation of T. was probably achieved by the help of an enterprising section of the nobles, who clung tenaciously to their privileges, and could not endure the constitutional recognition of the *plebs*. It does not appear that the whole of the senators connived at or even approved of T.'s

procedure. We are expressly told that he drove numbers of those whom he mistrusted into exile; in other words, he persecuted and banished the adherents of the Servian policy of conciliation. Like a Turkish tyrant, he surrounded himself with a body-guard—another indication of the original insecurity of his position, and strengthened himself by foreign alliance, marrying his daughter to Octavius Mamilius, Prince of Tusculum. By means of subtle and unscrupulous intrigues, he obtained or consolidated the Roman hegemony in Latium; offered sacrifice in the name of all the Latins at the Alban Mount; fused the contingents of the latter with the Roman legion; put to death as traitors such of their chiefs as opposed him (e. g., Turnus Herdonius); and, at the head of the combined forces, penetrated into the Volscian marshes, and subdued the natives. On his return, he completed the building of the Capitol, which the Elder T. had begun, and deposited in the vaults the Sibylline books he had curiously acquired. See Sibyl. He next conquered the town of Gabii (where many of the banished nobles had found shelter), through an elaborate stratagem, in which his son Sextus played the principal part. But his lavish expenditure both in war and peace necessitated the imposition of heavy taxes, and murmurs of discontent were heard among the people. The patience both of plebs and patricians was beginning to give way. Coincident with this state of things, a fearful omen was beheld: from the altar in the royal palace crept forth a serpent, and devoured the entrails of the victim. T. sent two of his sons, Titus and Aruns, to Delphi to consult the oracle. They were accompanied by their cousin, L. Junius Brutus (q. v.), who had long feigned himself a fool in order to save his life, for T. had killed his father and brother in order to possess himself of their great wealth. On their return, they found that the king had opened war upon the Rutuli, and was besieging Ardea, whereupon they joined the Roman camp. Here occurred, between Sextus and Collatinus, the famous dispute about the virtues of their respective wives, which led to the rape of Lucretia. The details of this legend are so familiar that it is unnecessary to recount them. Suffice it to say that it roused such a storm of indignation, that the people of Collatia (where the shameful deed was done) rose in arms, and renounced their allegiance to Tarquinius. Brutus carried the news to Rome, and the senate, fired with a righteous anger, deposed the tyrant; finally, the army before Ardea also revolted. T. and his sons were obliged to flee, and an aristocratic republic was constituted at Rome. Three different attempts were made to restore T. by force: first, by his own Etruscan kinsmen of Tarquinii; second, by Lars Porsena (q. v.) of Clusium; and third, by his son-in-law, Octavius Mamilius, 'prince of the Latian name,' all of which, according to the legend, failed; and at length T., utterly baffled and beaten, retired to Cumæ, where he died, a wretched and childless old man, for all his sons had met death before him.

TA'RRAGON. See Artemisia.

TARRAGO'NA, a seaport of Spain, chief city of the modern province of the same name, stands on the Mediterranean shore, at the mouth of the Francoli, 60 miles west of Barcelona. It consists of two portions—the upper (the ancient) and the lower (the modern) towns. The former stands on a hill 720 feet high, and is girdled with ramparts. The lower town, completely separated from the higher by a line of works, is regular and open, and is defended by two forts. The beautiful cathedral, in Gothic and Norman, and which dates from the middle of the 12th c., is the principal edifice. Of its industries, brandy-distilling and the manufacture of olive oil are the chief. The harbour is safe for the vessels that visit Tarragona. Population about 19,500.

T., called by the Romans *Tarraco*, was founded by the Phœnicians (who called it *Tarchon*, citadel), and afterwards became the capital of the Roman province of Tarraconensis. Among the Roman antiquities are the remains of an amphitheatre, which has been used as a quarry; a magnificent aqueduct, 96 feet high, and 700 feet long—still in use—and near the town the Tower of the Scipios, much decayed. T. was taken and cruelly sacked, in June 1813, by the French under Suchet.

TA'RRYTOWN, a village of New York, U. S., on the east bank of the Hudson River, 27 miles north of New York city. It is beautifully situated on a lake-like expansion of the river, called the Tappanzee, surrounded with fine scenery, and filled with elegant residences. It has 6 churches and 4 academies, and is noted as the scene of the capture of Major André. Pop. (1880) 3025.

TA'RSHISH, probably the same as *Tartessus*, a city and emporium of the Phœnicians in Spain, somewhere near the mouth of the Guadalquivir. It is frequently mentioned in Scripture, notably so in connection with the prophet Jonah, who took ship for T. when he sought to 'flee from the presence of the Lord.'

TA'RSIA-WORK, a beautiful kind of marquetry made in Italy. It is produced by inlaying pieces of coloured wood so as to represent figures and landscapes. That of Sorrento is very celebrated; and lately, many fine pieces of this work have been made in Perugia. It is usually applied to the decoration of cabinet-work.

TA'RSUS, anciently the chief city of Cilicia, and one of the most important in all Asia Minor, situated on both sides of the navigable river Cydnus, in the midst of a beautiful and productive plain, and about 18 miles from the sea. It was a great emporium for the traffic carried on between Syria, Egypt, and the central region of Asia Minor. In the time of the Romans, two great roads led from T., one north across the Taurus by the 'Cilician Gates,' and the other east to Antioch by the 'Amanian' and 'Syrian Gates.' T., judging from its name, was probably of Assyrian origin; but the first historical mention of it occurs in the *Anabasis* of Xenophon, where it figures as a wealthy and populous city, ruled by a prince tributary to Persia. In the time of Alexander the Great, it was governed by a Persian satrap; it next passed under the dominion of the Seleucidæ, and finally became the capital of the Roman province of Cilicia. At T, Antony received Cleopatra, when she sailed up the Cydnus, with magnificent luxury, disguised as Aphrodite. Under the early Roman emperors, T. was as renowned for its culture as for its commerce, Strabo placing it, in respect to its zeal for learning, above even Athens and Alexandria. It was the birthplace of the Apostle Paul, who received the greater part of his education here; and here the Emperor Julian was buried. Gradually, during the confusions that accompanied the decline of the Roman and Byzantine power, it fell into comparative decay; but even yet, it is—under the name of *Tarso* or *Tersus*—the most considerable place in the south-east of Asia Minor, has a pop. of 30,000 (in winter); and exports corn, cotton, wool, copper, gall-nuts, wax, goats' hair, skins, hides, &c.

TA'RTAN, or PLAID, a pattern woven in cloth, in which bands of different colours are woven or printed side by side, both the warp and weft way

of the material, thus giving the well-known checkered pattern. This is probably the oldest pattern ever woven; at all events, the so-called shepherd's plaid of Scotland is known to have a very remote antiquity amongst the eastern nations of the world. The plaid pattern admits of a very great variety of modifications, by the introduction of different colours, and by varying the amount of each colour employed. These coloured plaids were in great favour in the Highlands of Scotland, where each clan wore a particular kind as its distinctive dress.

TA′RTAR, a mixture of bitartrate of potassium and tartrate of calcium (see TARTARIC ACID), is a deposit formed from wine, and known in its crude form as Argol (q. v.). About 900 tons annually of this substance are imported into Great Britain, from the chief wine-producing countries of Europe and the Cape of Good Hope.

The word *Tartar*, which gives the name to tartaric acid, is derived from the Greek *Tartaros*, hell. 'It is called *Tartar*,' says Paracelsus, 'because it produces oil, water, tincture, and salt, which burn the patient as Tartarus does.'

TARTAR, CREAM OF. See TARTARIC ACID.

TARTAR, FOLIATED EARTH OF, an old name for acetate of potash, in consequence of the foliated satiny masses in which that salt occurs.

TARTAR OF THE TEETH is a deposit of salts of lime and organic matter from the saliva, and usually occurs most abundantly on the inferior incisors. If it is suffered to accumulate, it causes inflammation and absorption of the gum, and gradual loosening of the teeth. The accumulating of this substance may usually be prevented if due attention is paid to the cleaning of the teeth. 'The teeth,' says Dr Druitt, 'should be cleaned at least twice a day with a soft tooth-powder (precipitated chalk is best) and a little soap. The hairs of the tooth-brush should be soft, and not too closely set, so that they may penetrate the better into the interstices of the teeth.' When the tartar has accumulated to any extent, it must be removed by the *scaling instruments* of the dentist.

TARTAR, SOLUBLE, a term applied by some chemists to neutral tartrate of potash, and by others to borotartaric acid. See TARTARIC ACID.

TARTA′RIC ACID. Ordinary tartaric acid, $C_4H_6O_6.H_2O$, is usually seen in the form of colourless, transparent, oblique, rhombic prisms, which are not affected by the action of the air, have an agreeable acid taste, and are soluble in water and alcohol. The crystals when gently warmed become strongly electric, the opposite sides of the crystals exhibiting the opposite forms of electricity. On heating tartaric acid to about 340°, it fuses; and at a slightly higher temperature, it becomes successively changed, without losing weight, into two metameric acids, *metatartaric* and *isotartaric* acids, the former of which is bibasic and the latter monobasic. At about 374°, two atoms of the acid lose one equivalent of water, and *ditartaric acid*, $C_8H_{10}O_{11}.H_2O$, is formed. If the same temperature be maintained a little longer, half the basic water is expelled, and *tartrelic acid*, $C_4H_4O_5.H_2O$, is formed; and finally, all the basic water is driven off, and *anhydrous tartaric acid*, or *tartaric anhydride*, $C_4H_4O_5$, remains in the form of a white porous mass insoluble in water, alcohol, or ether. If, however, it be allowed to remain long moist, it gradually becomes converted into crystallised tartaric acid. Finally, on distilling tartaric acid in a retort at a temperature of 400° and upwards, it is decomposed into certain gases and empyreumatic oily matters, water, and acetic, pyruvic (or pyroracemic), and pyrotartaric acids.

Oxidising agents, such as peroxide of lead or nitric acid, readily act upon tartaric acid, and convert it into formic and carbonic acids; and when fused with caustic potash, it splits up into acetic and oxalic acids. It is one of the strongest of the organic acids.

This acid occurs abundantly in the vegetable kingdom both in the free and combined state. It is found as a free acid in tamarinds, grapes, the pine-apple, &c.; and in combination with potash and lime in tamarinds, grapes, mulberries, and the unripe berries of mountain-ash, and in small quantity in the juice of many other vegetables. It is, however, from Argol (q. v.), a product of the fermentation of grape-juice, that the tartaric acid of commerce is obtained. The details of the process may be briefly described as follows: Argol, or crude bitartrate of potassium, is dissolved in boiling water, and chalk is added as long as effervescence occurs. An insoluble tartrate of calcium is precipitated, and tartrate of potassium remains in solution. This tartrate of potassium is converted, by the addition of chloride of calcium, into insoluble tartrate of calcium and soluble chloride of potassium. The tartrate of calcium obtained by these two operations, if treated with sulphuric acid, readily yields free tartaric acid in solution, with sulphate of calcium as a precipitate. The filtered liquid, when cooled and evaporated, yields tartaric acid in crystals.

Tartaric acid is used in large quantity by calico-printers and dyers for the removal of certain mordants, and is much employed in medicine in the preparation of effervescing draughts and for other purposes.

Tartaric acid is tetratomic, and for the most part dibasic, two of the hydrogen-atoms being easily replaced by metals, and the other two by alcoholic acid radicles. With monatomic metals it forms acid, neutral, and double salts; thus with potassium it forms acid tartrate of potassium ($C_4H_5KO_6$), neutral salts of potassium ($C_4H_4K_2O_6$), and tartrate of sodium and potassium, or Rochelle salt ($C_4H_4KNaO_6.4H_2O$). With diatomic metals it forms neutral salts and double salts, viz., neutral tartrate of barium ($C_4H_4Ba_4O_6$), and tartrate of barium and potassium ($C_8H_8Ba''K_2O_{12}$). With triatomic metals it forms a peculiar class of salts, best known in the case of antimony, the acid tartrate of which is $C_4H_5(SbO)O_6$, tartrate of potash, and antimony (tartar emetic) ($C_4H_4K(SbO)O_6$), and neutral tartrate of antimony ($C_4H_4(SbO)_2O_6$). The neutral tartrates of the alkali metals are very soluble in water, but all tartrates are insoluble in alcohol. The neutral tartrates of the earth metals and heavy metals are mostly of sparing solubility in water.

Tartrate of potassium, $C_4H_4K_2O_6$, a soluble salt, which crystallises with difficulty, and is formed in preparing tartaric acid from *bitartrate of potassium*, $C_6H_5KO_6$. This salt is prepared from argol by extraction with boiling water, which dissolves about one-sixth of its weight. As it is much more insoluble in cold water, of which it requires 240 parts, it crystallises readily as the hot solution cools. The snowy white rhombic prisms which are thus deposited constitute *cream of tartar*. When heated to redness in a covered crucible, a charred mass, consisting of carbonate of potassium and charcoal in a fine powder, remains, and is used in the laboratory for reducing operations under the title of *black flux;* and if cream of tartar is deflagrated with twice its weight of nitre, *white flux*, also a reducing agent, consisting solely of carbonate of potassium, is obtained. *Tartrate of potassium and sodium* has been already described in the article ROCHELLE SALT. *Tartrate of potassium and iron*, or *Ferrum tartaratum*, $C_4H_4K(FeO)O_6$, and *Tartrate of ammonium and iron*, or *Ammonio-tartrate of iron*, $C_4H_4(NH^4)(FeO)O_2$, although the

latter is not included in the Pharmacopœia, are excellent medicinal preparations of iron. For the method of preparing them, the reader is referred to Neligan's *Medicines*, 6th ed. p. 658, &c. They occur in the form of brilliant, semi-transparent, reddish-brown scales, and are soluble in about their own weight of water at 60°. *Tartrate of potassium and boron*, known also as *soluble tartar* (although the term has also been applied to tartrate of potassium), or *soluble cream of tartar*, $C_4H_4K(BO)O_6$, has been employed medicinally, but is not now used. *Tartrate of antimony and potassium*, known also as *tartarised antimony* and *tartar emetic*, $C_4H_4K(SbO)O_6.\frac{1}{2}H_2O$, is one of the most valuable articles in the whole *Materia Medica*. This salt, obtained by a process which is given in the Pharmacopœia, occurs in the form of square prisms, which are soluble in about 15 parts of cold water and in 2 parts of boiling water. This salt is somewhat efflorescent, and when dried at 212°, loses all its water of crystallisation; its solution slightly reddens litmus, throws down an orange-coloured sulphide of antimony, if a current of sulphuretted hydrogen is passed through it, and has a very peculiar nauseous, metallic taste.

There is no very delicate test for tartaric acid. Its presence in a moderately strong solution may be detected by the addition of acetate of potassium, when a sparingly soluble bitartrate is soon separated, especially if the mixture be well stirred. All the tartrates on charring emit a peculiar odour resembling that of burned sugar.

A remarkable metameric modification of tartaric acid is known as *racemic* or *paratartaric acid*, or *uvic acid*, $C_4H_6O_6$. It is a frequent associate of tartaric acid, but is especially abundant in the grapes of the Vosges district. While in most respects it exhibits a close resemblance to tartaric acid (the two acids having the same composition, yielding, when exposed to heat, the same products, and their salts corresponding in the closest manner), it may be distinguished and separated from it by the following points of difference. It crystallises more readily from solution; it contains two equivalents of water of crystallisation; it is less soluble in alcohol; and the racemate of calcium is soluble in hydrochloric acid, and is precipitated unchanged on adding ammonia. Its most important difference, however, is, that its solution does not rotate the plane of polarisation, while a solution of ordinary tartaric acid exerts a well-marked right-handed rotation.

The brilliant researches of M. Pasteur on the optical and chemical properties of tartaric and racemic acids, have opened up a new and most important field of investigation in relation to the molecular composition of organic bodies. We shall give the briefest possible abstract of his remarkable discoveries, and must refer for fuller information to his numerous Memoirs in the *Comptes Rendus*, *Annales de Chimie*, and other French scientific journals. He has proved that racemic acid is a mixture of ordinary tartaric acid (to which, from its optical property, he applies the term *dextro-racemic acid*) and of an acid which produces left-handed rotation, to which he gives the name *lævo-racemic acid*. (These acids are also known as *dextro-tartaric* and *lævo-tartaric acids*.) He found that, by saturating racemic acid with soda and ammonia, and allowing this solution to crystallise slowly, two varieties of crystals are obtained, which may be distinguished by their form, in the same way as the image and the reflection of the image in a mirror differ; or as right-handed and left-handed. If the two kinds of crystals are separated, and then dissolved, each solution is found to act powerfully on polarised light, but in opposite directions. On separating these acids from their bases, and mixing equal parts of concentrated solutions of each, racemic acid is again formed, which exerts no action on a polarised ray. M. Pasteur has subsequently made the discovery, that racemic acid may be artificially produced by the action of heat upon certain compounds of tartaric acid (such as tartrate of cinchonine or tartaric ether), which are capable of resisting a high temperature. The formation of racemic acid in this way is accompanied by the production of another modification of tartaric acid, which he calls *inactive tartaric acid*, which, like racemic acid, has no action on polarised light, but, unlike it, cannot be resolved into dextro and lævo racemic acids.

Tartaric acid and the tartrates, in their relation to medicine, are of considerable importance. Pure *tartaric acid*, in small doses diluted largely with water, forms a good refrigerant drink in febrile and inflammatory affections, and is much employed for this purpose in hospitals, &c., as being cheaper than citric acid. It has been stated that persons addicted to habitual drunkenness have been reclaimed by the following treatment. A few crystals of the acid are dissolved in two small tumblers of water, and taken in the morning fasting, an hour intervening between the tumblers. The painful feeling of sinking and craving of the stomach, of which such persons usually complain, is said to be removed by these acid draughts. Under the name of *acidulated drops*, lozenges composed of this acid, sugar, and oil of lemons, are largely employed in mild sore throats and colds. The principal medical use, however, of tartaric acid is in the preparation of effervescent draughts, when added to alkaline carbonates; and in the composition of Seidlitz Powders (q. v.). *Tartrate of potassium* is a mild but efficient purgative in doses of from two to six drachms, which is perhaps hardly so much used as it deserves. In passing through the system, it becomes converted into carbonate, and thus renders the urine alkaline. *Acid tartrate*, or *bitartrate of potassium*, commonly known as *cream of tartar*, in full doses, acts as a sharp purgative, but is generally prescribed with some of the milder vegetable cathartics. When administered in small repeated doses (from a scruple to a drachm), in a large quantity of water, it largely increases the secretion of urine, and is consequently of great service in dropsy. It may be agreeably given in either of the following forms: (1) *Imperial*, which is prepared by dissolving a drachm of cream of tartar in a pint of boiling water, and flavouring with lemon-peel and sugar. In incipient dropsy, a couple of tumblers of this mixture, with half a glass of good hollands in each, are strongly recommended by Dr Neligan as an after-dinner drink. The proportion of cream of tartar to the pint of water may be gradually increased to two drachms. (2) *Cream of tartar whey* is prepared by boiling 100 grains of the salt in a pint of new milk, and removing the curds by straining. Either of these drinks may be safely taken to any extent agreeable to the patient. *Tartrate of iron and potash*, the *Ferrum tartaratum*, or *Tartarated iron*, of the Pharmacopœia, is a mild chalybeate tonic, which, in consequence of its somewhat sweet taste, is well adapted for children. It occurs in transparent scales of a deep garnet colour, is soluble in water, and sparingly soluble in spirit. The dose varies from five grains to a scruple, three times a day, either given with honey or treacle, or dissolved in some aromatic water. The *wine of iron* (*Vinum Ferri* of the *Pharm. Brit.*) consists of sherry with tartrated iron in solution. Each drachm ought to contain one grain of the salt. The *tartrate of iron and ammonia*, or *ammonio-tartrate of iron*, closely resembles in its action the tartrate of iron and potash. Although

not in the *Pharm. Brit.*, it is 'an excellent preparation of iron, void of all astringency. Its not disagreeable taste, its solubility in water, its compatibility with the alkaline carbonates, and the permanency of its composition, give it an advantage over most of the other preparations of iron. It is peculiarly suited as a tonic for those derangements of the uterine organs in which ferruginous salts are indicated.'—Neligan's *Medicines*, 6th ed. p. 645. The dose is from five to eight grains, and it may be prescribed in the form of powders, pills, or solution; or made into a bolus with honey. *Tartar emetic*, in doses of from $\frac{1}{12}$th to $\frac{1}{8}$th of a grain, frequently repeated, acts as a diaphoretic or sudorific; nausea sometimes accompanies the diaphoresis, but it has the advantage of increasing the tendency to perspiration. The addition of the compound tincture of lavender tends to prevent the supervention of vomiting. Tartar emetic in these small doses is of great service in febrile disorders, in the hæmoptysis of phthisis, in obstinate cutaneous diseases, &c. *Antimonial wine* consists of sherry holding tartar emetic in solution in the proportion of two grains to the ounce. The dose, to produce a diaphoretic action, is 20 or 30 minims every hour. If we require an expectorant action—as in acute pneumonia or bronchitis—the salt should be given in still smaller doses, as from $\frac{1}{16}$th to $\frac{1}{12}$th of a grain. Tartar emetic, in doses of two or three grains, dissolved in water, acts as a powerful emetic, and at the same time produces much nausea and depression, and not unfrequently purging. The vomiting seldom occurs till about twenty minutes after the draught has been taken. If tartar emetic is thus given at the commencement of febrile or inflammatory affections, it will often cut short the impending disease. With this view, it is employed in continued fever, croup, hooping-cough, &c. It used to be given to relax the muscular system, in cases of strangulated hernia and dislocation; but chloroform is far better for these objects. In cases of poisoning, it is inferior to sulphate of zinc. It is expedient to take the emetic dose in parts, as too powerful an effect is thus prevented. Two grains, which are generally sufficient, must be dissolved in eight ounces of water, of which a quarter should be taken every ten minutes till vomiting ensues. The patient should walk gently about his room between the doses. If a large dose (of one, two, or even three grains) be repeated every second hour, the nausea, vomiting, and purging (which often follows a full dose) cease after two or three such doses, and the main action seems to be exerted in depressing the circulation and lowering the pulse. Hence, tartar emetic given in this way is a direct sedative or contra-stimulant, and is of great service in pneumonia and pleurisy. 'As a contra-stimulant,' says Neligan, 'tartar emetic is given in doses of from half a grain to two grains every hour or second hour, dissolved in one or at most two ounces of orange-flower water. The first dose or two should not exceed half a grain, and the patient should not be permitted to drink, so as, if possible, to avoid the production of vomiting. When once a tolerance of the medicine is produced in the system, the quantity taken may be rapidly increased.'—*Op. cit.*, p. 418. Lastly, tartar emetic, when applied to the skin, produces a crop of pustules, which ulcerate, and discharge purulent matter. In consequence of this property, tartar emetic, either in the form of ointment or of saturated solution, is often employed as a counter-irritant in various affections of the viscera of the chest and abdomen, in diseases of the joints, &c. The *ointment* is applied by rubbing about half a drachm on the skin night and morning. In two or three days, pustules begin to appear, when the further application of the ointment should be temporarily suspended. The saturated solution is a cleaner preparation than the ointment, and acts more speedily. It is applied by means of pledgets of lint soaked in it. Tartar emetic, in excessive doses, or in small repeated doses, acts as an irritant poison. Dr Taylor has reported 37 cases of poisoning by this agent, of which 16 were fatal. The smallest fatal dose was in a child *three-quarters of a grain*, and in an adult *two grains*, but in the last case there were circumstances which favoured the fatal action of the poison. The symptoms occurring in chronic poisoning by this salt are 'great nausea, vomiting of mucus and liquids, great depression, watery purging, followed often by constipation of the bowels, small contracted and frequent pulse, loss of voice and muscular strength, coldness of the skin, with clammy perspiration, and death from complete exhaustion.' A considerable number of cases are on record in this country in which murder has been perpetrated by the slow action of tartar emetic. The most important of them are referred to by Dr Taylor in his *Medical Jurisprudence*, pp. 146 and 250, to which must be added the Pritchard case in Glasgow (1865). The *Pharmaceutical Journal* for October 1865 contains directions, by Messrs T. and H. Smith of Edinburgh, for preparing an antidote to be prescribed after a large dose of tartar emetic has been taken. The ingredients are solution of perchloride of iron and calcined magnesia.

TA'RTARS, or, more properly, TATARS, was originally a name of the Mongolic races, but came to be extended to all the tribes brought under Mongolic sway by Genghis Khan and his successors, including Tungusic and Turkic races. The term is therefore not to be considered as ethnological, though all, or almost all, the peoples included under it, in its widest sense, belong to the Turanian family, but is rather to be understood in the same sense as the term 'Franks' used by Mohammedans. In the classification of languages, Tataric has become the distinctive name of that class of Turanian languages of which the Turkish is the most prominent member, while the Mongolic form a separate class. See TURANIAN LANGUAGES.

TA'RTARUS (Gr. *Tartaros;* the name is probably onomatopœic, the reduplication being designed to express something *terrible* or disagreeable, like *Barbaros*, *Karkaron*, and many other words), according to Homer, is a deep and sunless abyss, as far below Hades as earth is below heaven, and closed in by iron gates. Into T., Zeus hurled those who rebelled against his authority, as, e. g., Kronos and the Titans. Afterwards the name was employed sometimes as synonymous with Hades or the underworld generally, but more frequently to denote the place where the wicked were punished after death—Lowest Hell, in fact. A noticeable feature about these punishments is their congruity with the nature of the offences perpetrated. See HEAVEN and HELL.

TA'RTARY (properly TATARY) is the name under which, in the middle ages, was comprised the whole central belt of Central Asia and Eastern Europe, from the Sea of Japan to the Dnieper, including Mantchuria, Mongolia, Eastern Turkestan, Independent Turkestan, the Kalmuck and Kirghis steppes, and the old khanates of Kasan, Astrakhan, and the Crimea, and even the Cossack countries; and hence arose a distinction of T. into European and Asiatic. But latterly the name T. had a much more limited signification, including only that tract bounded on the N. by Siberia, and on the S. by China and Tibet, along with Independent Turkestan; and at the present day, many writers apply it as a synonym for Turkestan (q. v.).

TARTRA'LIC ACID. See TARTARIC ACID.

TARTRE'LIC ACID. See TARTARIC ACID.

TARTUFFE, the name of the chief character in Molière's most celebrated comedy, which has become a synonym in all languages for a hypocritical pretender to religion. The original of the character was most probably a certain Abbé de Roquette, a parasite of the Prince de Conti. The name is said to have suggested itself to Molière on the occasion of a visit to the papal nuncio, where he saw the pious and solemn countenances of the nuncio's courtiers suddenly lighted up with ecstatic animation by the appearance of a seller of truffles—in Italian, *tartuffoli*. This play excited a greater commotion than perhaps any other production of the kind ever did. It was written in 1664; but before it was brought on the public stage, partial representations of it in private companies had made its character known, and raised the alarm of the priests, who believed themselves to be specially satirised therein. Uniting with the many enemies whom Molière had already made for himself by lashing physicians, fops, and fools of all kinds, they used every means in their power to prevent the public representation of the play. The Archbishop of Paris threatened with excommunication all actors who should take any part in the performance, and even those who should only read it; and one dignitary went so far as to declare that Molière—whom he called a devil in human form—was deserving of the stake. It was not till 1669 that Molière succeeded in getting the play publicly acted in presence of Louis XIV.; and then it had an uninterrupted run for three months, to the great vexation of all hypocrites.

TASHKE'ND, a town (till 1865) of the khanat of Khokan, in Independent Turkestan, 92 miles north-north-west of Khokan, the capital, is situated on the north bank of the Saralka, a small feeder of the Djirhik River, an impetuous torrent, which empties itself into the Sir-Daria. It is the chief commercial town in the khanat, is the centre of the transit-trade between Bokhara, Khokan, and Chinese Tartary, and has extensive trading relations with Orenburg and Petropavlovsk. This commercial eminence renders it one of the most important cities of Central Asia. Vambery (*Travels in Central Asia* during 1863), who supplies us with the above information, does not describe the town or estimate its population; but from older authorities we learn that, like most of the cities of Central Asia, it stands in a fertile plain, is protected by a high wall of sun-dried bricks, 12 miles in circumference, through which entrance is obtained by 12 gates. Within the walls are numerous gardens and vineyards, interspersed among the houses; the houses themselves are built of mud, and thatched with reeds. The streets are narrow and dirty. The chief buildings are the castle—which is fortified, and is now the residence of the governor—various mosques, colleges, old temples, and a bazaar. The chief manufactures are gunpowder, silk and cotton goods, and iron. By a census taken in 1871 the population was 78,125. T. is also important in a military point of view, as the key to the khanats of Khokan and Bokhara, and mainly for this reason was long coveted by Russia. It was captured by the Russians in 1854, but soon relinquished; was retaken June 15, 1865, and the state of Khokan was annexed to Russia.

TASMA'NIA, formerly VAN DIEMEN'S LAND, a considerable island in the South Pacific Ocean, between the parallels of 40° 40'—43° 40' S. lat., and between 144° 30'—148° 30' E. long, lying to the south ot, and separated from Australia by Bass's Strait. Its greatest length, from Cape Grim, on the north-west, to Cape Pillar, on the south-east, is 240 miles; and its greatest breadth from east to west, 200 miles; its area, including the adjacent islands, about 26,300 sq. miles. The capital is Hobart Town, with a pop. of 19,449, situated at the base of Mount Wellington, on the western shore of the estuary of the river Derwent. The second chief town is Launceston, with a pop. of 10,359, situated at the head of the estuary of the Tamar, formed by the junction of the North and South Esk rivers. In the year 1870, the population consisted of—males, 52,853; females, 46,475; a total of 99,328 souls. In 1881 the total population amounted to 115,705, of whom 61,162 were males, and 54,543 were females. Hobart Town and Launceston are connected by the electric telegraph, and by a railway 133 miles in length. A line 45 miles long also connects Launceston and Deloraine, and a line of 30 miles connects Deloraine with the Mersey.

Physical Features.—The south-eastern coast of T. is deeply indented by the estuaries of the Derwent and Huon, Storm Bay, the inlet of Pitt Water, and Frederick Henry Bay. The last is protected on the south-east by Tasman's Peninsula, reserved as a penal settlement for the colony. The chief indentations on the west coast are Macquarie Harbour (formerly a penal settlement, but now uninhabited), and Port Davey. On the east coast are Oyster Bay, between Freycinet's Peninsula and the mainland; and Spring Bay, sheltered on the east by Maria Island. On the north coast, besides the estuary of the Tamar, there are numerous smaller harbours and rivers, accessible to vessels of from 30 to 300 tons. The chief of these are Circular Head, Port Sorell, and the rivers Mersey, Forth, Leven, Don, and Inglis. The scenery is of a bold mountainous character, varied by deep narrow valleys, extensive undulating tracts of country, and open plains of limited extent. Among the principal mountains are Ben Lomond (5002 feet), Cradle Mount (5069 feet), Ironstone Mount (4736 feet), Mount Barrow (4644 feet), Mount Wellington (4166 feet), with many others exceeding 4000 feet in height. Embosomed among the central mountains, at an average height of about three thousand feet, are numerous lakes, with a united area of about 170 sq. m., which feed the greater part of the rivers draining the south-east slope of the island. With the exception of the reclaimed lands, the basaltic plains, and limited tracts which are unfavourable to the growth of timber trees, the whole island is more or less densely wooded. The vast forests of the western portions of the north and south coasts are extensively utilised for timber, and in the former, the work of reclaiming the rich heavily-timbered lands is rapidly progressing. But the major part of the western half of the island is entirely uninhabited, its soil, climate, and inaccessible position offering little inducement to the settler.

Geology and Mineralogy.—A geological survey of Tasmania was commenced in 1859. The bed-rocks of the western districts of the island, from Bass's Strait to South-west Cape, consist of vast bands of slates, schists, and quartz rock, belonging to the Azoic or Metamorphic series. Next to these come Lower Palæozoic slates, with conglomerates and dark compact limestones, the latter highly charged with Silurian fossils. Unconformably upon the upturned edges of these rocks lie Upper Palæozoic sandstones, mudstones, limestones, and conglomerates, also traversed by dykes and masses of greenstone and basalt, and with these, reaching an altitude of 4000 feet above the sea-level. In the south-east districts, from the South Esk River on the north to the Huon on the south-west, the lower rocks are entirely absent, or

concealed beneath the Upper Palæozoic beds. In the north-east district, the lower rocks again make their appearance, associated with granite and greenstone, and occasionally traversed by dykes and veins of the true auriferous quartz. Here, again, they are overlaid by Upper Palæozoic rocks, extensively denuded, and exposing seams of coal from 2 feet to 14 feet thick, at various elevations. Tertiary rocks are sparingly distributed. At the mouth of the river Inglis, on the north coast, are beds of a whitish freestone, attaining in places a thickness of 120 feet, and containing recent shells, with extinct species of *Trigonia*, *Terebratula*, *Cypræa*, *Voluta*, &c. Tertiary lignites are found in the sandy clays of the valleys of the Derwent and Tamar, with impressions of leaves of unknown trees and plants. Over the greater part of the basin of the South Esk, comprising an area of more than 1000 sq. m., extensive deposits of clays, sands, and quartz drift are met with. No distinct traces of glacial action have been observed; but the thick beds of gravel, and the boulders, which must have travelled many miles from their parent rock, afford evidence of some powerful transporting agency, and were probably deposited in their present sites by the action of icebergs slowly drifting northwards at some period prior to the last general elevation of the land.

The igneous rocks are everywhere present in great variety. The islands of the Furneaux group in Bass's Strait are chiefly of granite, and form the connecting links which join the north-east angle of T. to the Great Dividing Range of Eastern Australia. The auriferous drifts of Fingal have for years given fair returns to a limited number of miners, and its quartz reefs and deep leads will yield gold in paying quantities, when enterprise and skill have been properly brought to bear upon them. Gold is also found in minute particles everywhere in the quartz drift of the South Esk basin, and on the north and west coasts; but the mode of its occurrence, and the geological indications, preclude the expectation that it will ever be profitably extracted. Silver, tin, and antimony have been occasionally met with in the gold drifts. Copper occurs in thin veins, associated with galena, on the north coast, near the river Leven, and galena has been found elsewhere in the primitive limestones. Red and brown hæmatites, containing a large percentage of iron, occur at various points on the north coast, in large masses and lodes. Coal is worked in several parts of the island, chiefly for local consumption. The older limestones yield fine varieties of marble, and excellent building-stone is obtained from the green-stones, basalts, and Palæozoic sandstones.

Botany.—The flora of T. has been fully described in the botany of the antarctic voyages by Hooker and others. The majority of the species are common to Australia and Tasmania. Of those which are peculiar to the latter, many are limited to particular localities. The most widely diffused genera are the Eucalypti and Acaciæ, the former yielding the ordinary timber of the colony. The Blue Gum (*Eucalyptus globulus*) reaches a height of 350 feet, with a corresponding girth. The Blackwood (*Acacia melanoxylon*) and the Huon Pine (*Dacrydium Franklinii*) also yield valuable timber, which, together with the hardwoods from the Eucalypti, is largely exported to the neighbouring colonies. A species of Beech (*Fagus Cunninghamii*), locally known as the myrtle, and growing in great abundance in some parts of the island, also produces a highly valuable timber, which has not yet received the attention which it merits. There are many beautiful shrubs and plants, but the flowers are usually small and inconspicuous. All the common fruit-trees and culinary vegetables of England have been introduced, and grow with great luxuriance and vigour. Oranges and lemons are cultivated in some situations, but do not usually ripen their fruit. The introduction and cultivation of exotic trees and plants are energetically carried on in the Botanical Gardens under the direction of the Royal Society.

Zoology.—Of the 40 species of mammals, one half belong to the sub-class *Aplacentaria*, comprising the *Marsupiata* (kangaroo, wallaby, opossum, wombat, &c.), and two species of the singular order *Monotremata* (Ornithorhynchus and Echidna). Among the marsupial animals peculiar to T., the chief are the Thylacine (*Thylacinus cynocephalus*) and the Tasmanian Devil (*Sarcophilus ursinus*), both of which are sometimes very destructive to sheep in the outlying districts. The skin of the kangaroo is much prized for leather, and there is always a market for opossum fur. Whales and seals, formerly very abundant on the coasts, are now rare; but whaling is still extensively carried on in the adjacent seas. The birds of T. have been admirably described by Gould. The majority are identical with Australian species. The emu is extinct, and black swans are seldom seen in the settled districts. There is abundance of native game, which is now protected by act of parliament during the breeding season. A species of puffin (*Puffinus brevicaudus*), locally known as the mutton-bird, frequents some of the islands in Bass's Strait in countless numbers, and many thousands are annually slaughtered for the sake of their oil, and for food by the half-caste islanders. Fish are plentiful in the seas and rivers, the best being known by the local name of trumpeter, and reaching a weight of 40 lbs. There are 13 species of snakes, most of which are venomous, but accidents from their bite are of very rare occurrence. Many species of insects and crustaceans have been described by Erichson, Gray, Gunther, and others. A comprehensive and accurate account of the *fauna* of T. is still, however, a desideratum.

Fallow deer, and several of the English game-birds, have long been naturalised, and salmon have been introduced after several unsuccessful attempts.

Climate, Soil, Produce, &c.—The climate of T. is fine and salubrious. From observations taken at Hobart Town, and extending over a period of twenty years, the extreme of heat appears to be 105°, and of cold 29° 8′. The mean temperature of the hottest month (January) is 63° 57′, and of the coldest (July), 45° 82′, and of the whole year, 54° 92′. In some parts of the island, the temperature, even in winter, rarely sinks to 45°. Snow seldom falls in the settled districts, and does not lie on the ground except on the high table-lands of the interior. The average annual rain-fall at Hobart Town is 21·52 inches, and the average for the rest of the island about 35 inches, except in the western country and the high lands, where a fall of 75 inches has been registered in the year.

The agricultural lands may be divided into three classes—alluvial deposits, tertiary clays, and loamy soils, derived from the decomposition of different kinds of basalt. In their virgin state, some are marvellously productive. On new land, 100 bushels of oats, 70 bushels of wheat, and 15 tons of potatoes per acre, are not uncommon crops. The fertility of the soil has encouraged a system of slovenly farming. In many instances, the land has been cropped with wheat and oats for upwards of thirty years without any application of manure, or any rest save an occasional summer fallow. The export trade in the staple articles of produce has much fallen off of late years, partly because the neighbouring colonies have

begun to depend more upon their own resources, but partly also through the deterioration of the soil from improvident management, and the necessarily increased cost of production. There are skilled and careful farmers in every district, but they are exceptions to the rule. The open pastoral lands are admirably adapted for sheep. The wool from some of the larger establishments is much valued, and brings the highest price in the London market. The cattle and agricultural horses of some of the northern districts are unsurpassed in the colonies. Pastoral and agricultural associations have been formed to promote improvements in the system of farming, and to encourage the breeding and importation of pure stock. The extent of purchased lands was, in 1865, 3,413,810 acres, of which 340,457 acres were under cultivation. In 1871 the number of horses in the colony was 23,054; of cattle 101,540; and of sheep 1,305,489. For the same year the exports amounted to £740,638, the chief staple article being wool, in value £298,160; the imports were £778,087. In 1870—1871 the yield of wheat was 328,130 bushels; barley, 161,729; oats, 691,250; tobacco, 250,-047 lbs.; apples, 147,614 bushels; pears, 27,553 bushels.

Administration.—Since the passing of the 'Constitutional Act' in 1854, the governing authority has been vested in a parliament, consisting of the governor as the Queen's representative, and two elective Houses, the Legislative Council of 15, and the Assembly of 30 members. The qualification of voters is, for the former, a freehold of the annual value of £50; and for the latter a freehold valued at £100, or a £10 rental. Graduates of British universities, and members of the learned professions, are entitled, *ex officio*, to vote at the election of members of both Houses. One-third of the members of the Council retire every three years; those of the Assembly hold office for five years, except in the case of a dissolution by the governor. The revenue for the year 1871 was £269,715, of which a fourth was derived from the rental and sale of crown-lands. The upset price of land is £1 per acre, payable by instalments extending over eight years; but lots which remain unsold after being offered for sale by public auction, may be purchased, under certain restrictions, at greatly reduced rates. In the unsettled districts, large tracts of land are obtainable at nominal prices. In 1862, an act, known as 'Torrens's Real Property Act,' was passed to facilitate the transfer and conveyance of land. Property which has been brought under the operation of this act can be conveyed, without reference to value, upon payment of 10*s.* registration-fee, £1 for new certificate of title, and 2*s.* for forms. Mortgages can be effected on equally moderate terms. The total value of the land which had been dealt with under this act, up to 31st October 1864, was £230,000.

Religion and Education.—By the Constitutional Act, £15,000 is annually reserved for the support of religion, and is at present divided among the various religious denominations according to their respective numbers at the census of 1871. These were as follows: Episcopalians, 53·41 per cent.; Roman Catholics, 22·24; Church of Scotland, 6·69; Free Church of Scotland, 2·43; Independents, 3·96; Wesleyan Methodists, 7·23; and other sects, 3·03 per cent. The state grants are largely supplemented by endowments and by local contributions. For the support of elementary education, £12,000 a year is appropriated by parliament, the disbursement of which is intrusted to a Central Board, holding its sittings in Hobart Town. The system is based upon the principles established by the Irish National Board. The teachers are appointed by the Board, and are under the supervision of the inspector of schools. The following shews the progress which has been made since 1854. In 1854: Number of schools, 50; average number on rolls, 2734; average attendance, 2624; government aid, £6914; school fees, £882. In 1864: Number of schools, 97; average number on rolls, 4987; average attendance, 3763; government aid, £11,324; school fees, £3933.

For the promotion of higher education, provision is also made by the legislature. Two scholarships, each of the value of £200 a year, and tenable for four years at either of the English universities, are annually open to competition under the direction of the Council of Education, and exhibitions to the higher schools, with other local honours, are periodically awarded by the same body.

Aborigines.—The number of the aborigines at the first colonisation of T. has been variously estimated, but probably at no time exceeded 3000. There were several tribes occupying distinct parts of the island, and differing from each other in dialect and customs; but of a generally uniform type more nearly allied to the Negritos of New Guinea than to the aborigines of Australia. The average height of the men was from 4½ to 5½ feet; of the women, considerably less. Colour, a bluish black; the facial angle 75° to 80°; eyes, dark brown, with jet-black pupils; hair, sometimes lank, but generally crisp or woolly; forehead, high and narrow; limbs, lean and muscular; feet, flat, and turned inwards. Polygamy appears to have been tolerated: the women performed all menial duties, and were specially charged with that of carrying fire from place to place, when the temporary encampment was broken up. Their usual shelter was a 'break-wind,' constructed of boughs, but traces of rude huts have been observed. In summer, they went entirely naked, at other times wearing coverings made from the skins of the kangaroo and opossum, which formed their chief food. The coast tribes, at certain times of the year, lived almost exclusively on shell-fish, and the remains of their feasts have often been mistaken for recent marine deposits. Among other articles of food were the roots of the esculent fern, the heart of the tree-fern, and grass-tree (*Xanthorrhœa*), the seeds of the boobialla (*Acacia sophora*), and a singular fungus (*Mylitta Australis*), commonly known as 'native bread,' which grows under ground near the roots of decayed trees. No traces of cannibalism were observed. Their only weapons were the spear and waddy, a wooden club about 2 feet 4 inches in length. The early relations between the settlers and aborigines were friendly; but as the latter were gradually dispossessed of their favourite hunting-grounds, they became inveterately hostile. Shot down without mercy by the settlers, they revenged themselves by bloody reprisals, and for many years the unequal struggle continued, until their numbers were reduced to a few hundreds. In 1830, an attempt was made to drive the whole body into Tasman's Peninsula, by means of a cordon extending across the whole island, and gradually closing in towards the south-east; but it failed ridiculously, as might have been foreseen. In the following year, Robinson, a builder of Hobart Town, undertook to conciliate the surviving remnants of the various tribes, with a view to their removal to Flinders Island, and this he successfully accomplished, after four or five years of patient, self-denying labour. In spite of all the care bestowed upon these unfortunate people, their numbers rapidly decreased, and only 45 remained when the settlement was removed, in 1847, to a more convenient station, at Oyster Cove, near Hobart Town. In 1865 there were only six remaining. No children have been born among them for many years, and the race is now

wholly extinct, the last of the number having died a few years ago.

History.—The island was first discovered by Tasman on the 1st December 1642, and named by him Van Diemen's Land, in honour of his patron, the then governor of the Dutch possessions in the East Indies. During the next century, no visit is recorded; but between 1772 and 1802, partial surveys and explorations were made by English and French navigators. In 1803, Lieutenant Bowen was despatched from Sydney with a few soldiers and convicts to form a settlement in the south of T., which was finally fixed on the spot where Hobart Town now stands. In 1804, a settlement was formed near the mouth of the Tamar, which was removed in 1806 to the spot now occupied by the town of Launceston. From 1817, commenced a rapid increase in the number of free settlers, who received grants of land in proportion to the capital which they brought into the colony, and were subsequently further aided in the clearing and cultivation of their estates by the assignment of convicts as their servants. In 1825, T. was declared independent of New South Wales.

The colony was for a good many years agitated by the question of the disposal and management of the convicts, who were now becoming a prominent and formidable element in the community. At last, in 1853, transportation to T. and New South Wales was finally abandoned by the home government. The abolition of transportation, and the consequent cessation of a vast imperial expenditure, naturally produced a considerable depression in all branches of trade, especially in the southern districts. It is not surprising that the great body of the colonists, instead of setting themselves manfully to turn the true and natural resources of the country to the best account, have rather looked for some great discovery of rich gold-fields, or some gigantic works undertaken under the auspices of government, as the only means by which the prosperity of the colony was to be assured. But such a state of things must ultimately work its own cure. Viewed in a true light, the progress, social, material, and political, has presented a more hopeful aspect since the extinction of the convict system than at any earlier period. For years after the discovery of gold in Australia, the *expirees* of T. flocked in crowds to the neighbouring colonies, attracted by the prospect of richer gains, and glad to escape from police surveillance in a country where their antecedents were too well known. Those who remained had, for the most part, by this time become orderly, well-conducted members of the community, not to be distinguished from the immigrant population by whom they were surrounded. Necessity will in due time develop the enterprise and energy which have too long lain dormant. Some of the older settlements may prove inadequate to the maintenance of their former population, but the rich lands of the north coast offer to industrious settlers a field which is practically inexhaustible.

TASMA'NNIA, a genus of shrubs of the natural order *Magnoliaceæ*. *T. aromatica* is an evergreen bush of Van Diemen's Land, growing in the richest soils on the margins of rivers and in shady ravines, and sometimes forming thickets of large extent. Every part of the plant is highly aromatic and pungent. The fruit is occasionally used as pepper. This shrub requires protection from frost in England.

TASSISUDO'N, the capital of Bhotan (q. v.), stands on the right bank of the Godadda, an affluent of the Brahmaputra, in lat. 27° 30′ N. Many of the inhabitants, the number of whom has not been ascertained, are employed in manufacturing paper, and in making brass images and ornaments for their places of worship.

TASSO, Bernardo, an Italian poet of considerable distinction, but most famous as the father of the illustrious Torquato, was born at Bergamo, 11th November 1493. Both by his father's and mother's side, he was connected with the ancient family of the Tassi, known in the 13th c. for having organised and superintended the postal service in Italy, Spain, and Germany. His uncle, Luigi Alessandro, Bishop of Recanati, took charge of his education, and under his care he turned out a fine classical scholar, his love of poetry at the same time becoming every year more ardent. The assassination of the cardinal, in 1520, deprived him at once of protection and support, and for several years he wandered about Italy in a rather necessitous condition. Like his son, he was exceedingly fond of the patronage of noble lords and the smiles of noble ladies. After 1525, we find him high in favour with persons of influence. Guido Rangone, general of the pontifical forces, intrusted him with several missions, among others to the Prince of Salerno, who appointed him his secretary; and T. accompanied the prince on the expedition against Tunis in 1534. In 1539, he married, at Salerno, a young lady of Sorrento, Porzia de' Rossi, who added genuine merit to the advantages of birth, beauty, and fortune, and by whom he became the father of Torquato. The fall of the Prince of Salerno (who had incurred the enmity of Charles V.) brought with it the ruin of T.'s worldly prosperity, and he was obliged to seek for a new patron. He was not long in finding friends. Guidubaldo, Duke of Urbino, and Gugielmo, Duke of Mantua, strove for the honour of attaching the poet to their court. The latter succeeded, and named him governor of the city of Ostiglia, where he died 4th September 1569.

T.'s principal writings, chronologically arranged, are: *Rime* (Ven. 1531); *I tre Libri degli Amori* (Ven. 1537); *Ode e Salmi* (Ven. 1560); *L'Amadigi, Poema* (Ven. 1560); and *Il Floridante, Poema* (Mant. 1587). Of these, the principal is *L'Amadigi* (Amadis), which some Italian critics have not hesitated to place above the poem of Ariosto; but without adopting this extravagant estimate, we may justly admire it for the sweetness and elegance of its language, and for the beauty of its descriptions and comparisons.—For a good idea of the politics and literature of the time, see Seghezzi's edition of his *Lettere* (3 vols., Padua, 1733—1751), to which there is prefixed a biographical notice.

TASSO, Torquato, one of the greatest poets of Italy, was the son of the preceding, and was born at Sorrento in Naples, 11th March 1544. His earliest education was received from the Jesuits. During his childhood, T.'s father was an exile, but the affectionate solicitude of his mother well supplied the want of paternal care. In 1554, he went to Rome to join his father, and left his mother (whom he was destined never again to see) in a convent at Naples. At Rome, and subsequently at Bergamo, Urbino, Pesaro, and Venice, he continued to prosecute his studies. He assisted his father in copying, correcting, and even in completing his poem *L'Amadigi*, though as yet only 16 years of age. No wonder old Bernardo was delighted at the promise shewn by his son, and prophesied in his letters that Torquato would yet become a great man. Later, however, sad experience of the miseries of a poet's life, induced him to send T. to Padua, to study jurisprudence under the celebrated Panciroli. But whom the gods have made poetical can never sink into a lawyer. The youth remained at Padua a year, and wrote *Rinaldo* (Venice, 1562), a poem in 12 cantos,

the hero of which is the son of Aymon, and cousin of Roland. It belongs, therefore, to the class of heroic romances. After the first burst of anger was over, Bernardo forgave his son for following his example rather than his precept, and became prouder of T.'s genius than ever. T. now betook himself to the university of Bologna, to study philosophy, and is said to have distinguished himself by an extraordinary facility in the discussion of the most elevated and abstract themes—a circumstance that perhaps says more for his power of rhetoric than his power of speculation. On leaving Bologna, he spent some time with friends at Castelvetre, Modena, and Corregio, but returned to Padua at the request of his friend Scipio de Gonzaga, afterwards cardinal, who had established a literary academy there, of which T. became a member. It was during this second residence at Padua that he conceived the first idea of his great work, the *Gerusalemme Liberata*, a heroic record of the conquest of Jerusalem by the Crusaders under the command of Godfrey de Bouillon. Lamartine beautifully describes the mingled motives of the poet: 'Urged by piety no less than by the muse, Tasso dreamed of a crusade of poetic genius, aspiring to equal by the glory and the sanctity of his songs, the crusades of the lance he was about to celebrate.' The same critic goes on to observe, in allusion to the less noble passion for the applause of courts that marked the poet: 'The names of all the noble and sovereign families of the West would be revived in this epic catalogue of their exploits, and would attract to the author the recognition and favour of the great. . . . . Finally, the poet was himself a knight, noble blood flowed in his veins, to celebrate warlike deeds seemed, as it were, to be associating his name with those of the heroes who had performed them on the field of battle: thus religion, chivalry, poetry, the glory of heaven and earth, the hope of eternal fame, all combined to urge him to the undertaking.' Bernardo heard of his son's design with exulting joy, and blessed Heaven for making Torquato a greater genius than himself. Meanwhile (1565), T. had been introduced by Cardinal Luigi d'Este (to whom he had dedicated the *Rinaldo*) to his brother, Alfonso II., sovereign Duke of Ferrara. Here for a time he was supremely happy. Young, handsome, courteous, and with that proper tinge of melancholy in his disposition that possesses an irresistible charm for women, he soon became a universal favourite with the beauties of the court. While their bright eyes rained influence, T. painted his *Armida* and *Herminia* almost without effort. It is only just to add, that the attempt to seek the origin of his subsequent miseries and madness in a presumptuous passion for Leonora, sister of the Duke of Este, which was first encouraged, then repulsed, and finally punished with imprisonment, is utterly at variance with the notorious facts of the case. Space does not permit us to examine the question here, but it appears necessary to correct so radical an error, sanctioned as it is by the illustrious name of Goethe. T. courted, platonically and otherwise, various ladies of the court—a pretty chamber-maid even was not beneath his notice; but there is not a vestige of evidence to shew that he lifted his eyes to the sister of his sovereign, or that such a suspicion was ever harboured by the lady herself or her brother. In truth, his madness was connected in its origin more closely with his poetry than with his loves. Having finished his great epic about 1575, he sent a copy of it to a society of scholars, critics, and churchmen at Rome, to get their opinion of it. It would have been far better had he published the poem at once, without placing it at the mercy of critics who were delighted to have the opportunity of finding fault before the public was in a position to praise. The critics would then have been forced to swell the chorus of general admiration. T. was tortured by their waspish comments, and, with pitiable agonies, proceeded to make his work more agreeable to his incapable judges. Gradually a morbid melancholy overpowered his reason; the spites and jealousies that are never absent from a gay and pleasure-loving court, contributed to increase his mental disorder. He believed that invisible persecutors had denounced him to the Inquisition as a heretic. It was in vain that Alfonso and his sisters tried to calm the perturbations of his spirit, and even got the Inquisition to write him a reassuring epistle. His paroxysms increased in violence. Finally, one evening (17th June 1577), he drew his dagger in the apartments of the Duchess of Urbino, to stab a domestic whom he conceived to be one of his secret enemies; whereupon Alfonso had him conveyed to a prison-hospital for the benefit of his health, rather than to punish him. On the 20th of July, he made his escape, and fled across the Abruzzi to his birthplace, Sorrento, where he took refuge with his sister. The air of his native place quickly restored him to health; but no sooner had he recovered, than he began to yearn for the old excitements, begged Alfonso to take him back, and when that prince drily informed him that he might return if he pleased, T. greedily availed himself of the cold permission, and was soon as wretched as before. A new flight ensued, this time towards the north of Italy. The unhappy poet wandered at last half-naked into the city of Turin, where he was humanely received by the Marquis d'Este, brother of Alfonso. After some time, he again ventured to return to Ferrara (21st February 1579), but only to madden, almost as soon as he breathed its noxious air. Alfonso was again obliged to put him under constraint, in which he remained upwards of seven years, when the duke, at the request of several of his brother sovereigns, released him (5th July 1586). During the remainder of his life, T. lived chiefly at Naples. Almost the last incident of his career, was his visit to Rome to receive (like Petrarch) the honour of a public coronation on the Capitol. The excitement was too much for his ruined frame. A slow fever seized him; he was removed to the convent of Santo Onofrio, on the Janiculum, and there died, 25th April 1595, after a brief illness.—See Manso, *Vita di T. Tasso* (Nap. 1619); Jacobi, *Vindiciæ T. Tasse* (Gött. 1763); Serassi, *Vita del Tasso* (Rome, 1785); Black, *Life of T. Tasso* (Edinb. 1810); Ebert, *T. Tasso's Leben* (Leip. 1819); Zuccala, *Della Vita di Tasso* (Mil. 1819); Milman, *Life of T. Tasso* (Lond. 1850); Cibrario, *Degli Amori e della Prigione di Tasso* (Tur. 1862).

Besides his *Gerusalemme Liberata*, T. wrote a great number of works in verse and prose, among which may be mentioned *Rime, insiemi con altri Componimenti* (Ven. 1581); *Dialoghi e Discorsi* (Ven. 1586—1587); *Lettere Familiari* (Bergamo, 1588); *Rime* (Brescia, 1592—1593); and *Gerusalemme Conquistata* (Rome, 1593). The most complete edition of his works appeared at Pisa, 1821—1832, in 33 vols.

TASTE, Organ and Sense of. The principal seat of the sense of taste is the mucous membrane of the tongue, in which dissection reveals a *cutis* or *chorion*, a *papillary structure*, and an *epithelium*. Of the *cutis*, it is sufficient to remark that it is tough, but thinner and less dense than in most parts of the cutaneous surface, and that it receives the insertions of the intrinsic muscles of the tongue, which will be described when we treat of that organ generally. The *papillary structure* differs from that of the skin in not being concealed under the epithelium, but in projecting from the surface like the villi of the digestive canal, and it thus gives to the tongue its

well-known roughness. The *Epithelium* (q. v.) is of the scaly variety, as on the skin, but is much thinner on the tongue than on the skin. It is most dense about the middle of the upper surface of the tongue, and it is here that, in disordered digestion, there is the chief accumulation of *fur*, which in reality is simply a depraved and over-abundant formation of epithelium. The *papillæ* on the surface of the tongue are either *simple* or *compound*. The former, which closely resemble those on the skin, are scattered over the whole surface of the tongue in parts where the others do not exist, and they likewise participate in the formation of the compound papillæ, which, from their forms, are respectively termed (1) the *circumvallate* or *calyciform*, (2) the *fungiform*, and (3) the *conical* or *filiform*.

The *circumvallate* papillæ are not more than eight or ten in number, and are situated in the form of a V at the base of the tongue. Their function seems to be to secrete mucus, as well as to take part in the act of tasting. They consist of 'a central flattened projection of the mucous membrane of a circular figure, and from $\frac{1}{20}$th to $\frac{1}{12}$th of an inch wide, surrounded by a tumid ring of about the same elevation.'—Todd and Bowman, *Physiological Anatomy and Physiology of Man*, 2d ed. vol. i. p. 437. They are shewn in the figure of the surface of the tongue given in the article on that organ.

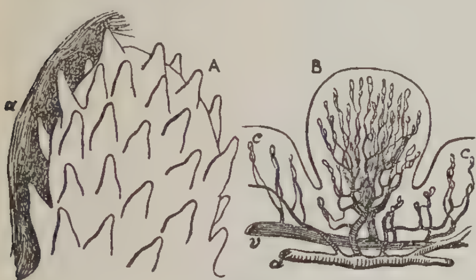

Fig. 1.

A, *Fungiform papilla*, shewing the simple papillæ on its surface; and at *a*, the epithelium investing them (magnified 35 diameters). B, a similar papilla, with the capillary loop of its simple papillæ injected; *a*, artery; *v*, vein. Around the base there is often a groove, which is here shewn; as also are the capillary loops, *c*, *c*, of two of the neighbouring simple papillæ (magnified 18 diameters).

The *fungiform* papillæ are scattered over the surface in front of the circumvallate papillæ, and about the sides and apex. They are usually narrower at the base than at the apex, where they are about $\frac{1}{30}$th of an inch in diameter. They are covered with simple or secondary papillæ, and

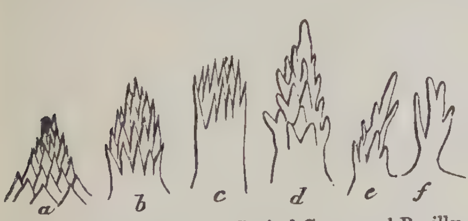

Fig. 2.—Various Forms of Conical Compound Papillæ.

a, *b*, *c*, provided with the stiffest and longest epithelium, and the simple papillæ much acuminated; *d* approximates to the fungiform, and *e* and *f* to the simple papillæ. (Magnified 20 diameters.)

their investing epithelium is so thin that the blood circulating in them gives them a red colour, which is not seen in the conical papillæ amongst which they are distributed. They contain nerves terminating in loops. The shape of the *conical* or *filiform* papillæ is indicated by their names; and even if they take little part in the sense of taste directly it is convenient to describe them here. Their average length is about $\frac{1}{10}$th of an inch. The structure of these papillæ will be better understood from the accompanying diagrams than from any verbal description. They terminate in long pointed processes, which are bathed by the mucus of the mouth, and are capable of moving in any direction, although they are generally inclined backwards. Some of the stiffer of these epithelial processes enclose minute hairs, of which several forms are depicted by Messrs Todd and Bowman, from whose *Physiological Anatomy* all the figures in this article are borrowed. These authors surmise, on structural grounds, that the filiform papillæ 'can scarcely share in the reception of impressions which

Fig. 3.

A, vertical section near the middle of the dorsal surface of the tongue, shewing the basement membrane on which lie *a*, *a*, fungiform papillæ; *b*, *b*, filiform papillæ, with hair-like processes; *c*, *c*, similar papillæ devoid of these processes. B, a filiform compound papilla, magnified 300 diameters: *a*, artery; *v*, vein; *c*, capillary loop; *d*, a secondary papilla deprived of *e*, epithelium; *f*, hair-like processes at the apex.

depend on the contact of the sapid material with the papillary tissue. The comparative thickness of their protective covering, the stiffness and brush-like arrangement of their filamentary productions, their greater development in that portion of the dorsum of the tongue which is chiefly employed in the movements of mastication, all evince the subservience of these papillæ to the latter function rather than to that of taste; and it is evident that their isolation and partial mobility on one another must render the delicate touch with which they are endowed more available in directing the muscular actions of the organ. The almost manual dexterity of the tongue in dealing with minute particles of

food is probably provided for, as far as sensibility conduces to it, in the structure and arrangement of these papillæ.'—*Phys. Anat. and Phys. of Man*, vol. i. p. 441. Notwithstanding the difference in their outward form and mode of arrangement, the simple papillæ, which have been detected by Todd and Bowman as scattered over the whole dorsum of the tongue (although concealed under the common sheet of epithelium), and those clothing the circumvallate and fungiform papillæ, do not seem to present any structural difference; and their epithelium, which is very thin, readily permits the transudation of sapid substances dissolved in the mucus of the mouth. With regard to the use of the singular configuration of the circumvallate and fungiform papillæ, 'it may be conjectured that the fissures and recesses about their bases are designed to arrest on their passage small portions of the fluids in which the sapid materials are dissolved, and thus to detain them in contact with the most sensitive parts of the gustatory membrane.'—*Op. cit.*, p. 441.

There has been much discussion regarding the precise seat of the sense of taste and the true nerves of taste. Although the surface of the tongue is the special seat of gustative sensibility in man, the sense of taste is by no means restricted to that organ, being diffused, in a less degree, over the soft palate, the arches of the palate, and the fauces. Moreover, the gustative sensibility varies on different parts of the surface of the tongue. It is generally allowed that acute taste 'resides at the base of the tongue, over a region of which the circumvallate papillæ may be taken as the centre, and also on the sides near the base. These parts are supplied solely by the glossal twigs of the glosso-pharyngeal nerves. Some writers, amongst whom are Valentin and Wagner, believe the middle and anterior parts of the dorsum of the tongue to be usually incapable of appreciating flavour; while numerous others hold the contrary opinion, with which our own careful and repeated experiments, on other persons as well as ourselves, quite accord. Sour, sweet, and bitter substances applied to the sides, and especially to the tip of the protruded tongue, we find to be at once distinguished; though, when placed on the middle of the dorsal region, they make little or no impression till pressed against the roof of the mouth. This region of the tongue is supplied almost solely by the lingual branch of the fifth nerve. We conclude generally, with regard to the tongue, that the whole dorsal surface possesses taste, but especially the circumferential parts, viz., the base, sides, and apex.'—*Op. cit.*, pp. 442, 443. The investigations of Messrs Todd and Bowman further shew that the soft palate and its arches are endowed with taste in some persons, but not universally, while they got no evidence in any case of gustative sensibility on the pharynx, gums, or elsewhere. The soft palate and its arches are supplied by palatine branches from Meckel's ganglion, and sparingly by the glosso-pharyngeal nerves. From (1) the evidence afforded by the anatomical distribution of the nerves to parts enjoying the sense of taste, (2) the evidence of experiments, in which the various nerves of the tongue were divided, and (3) the evidence afforded by disease, it may be safely inferred that the glosso-pharyngeal and the lingual branches of the fifth pair of nerves respectively participate in the sense of taste; and there is also reason to attribute a share to the palatine branches of the fifth.

Impressions of taste may be produced by a mechanical or chemical excitement of the gustatory nerves. A quick light tap of the finger on the tip of the tongue causes a taste, sometimes acid, sometimes saline, which lasts for several seconds; and galvanism acts similarly. If the surface of the tongue, near the root, be touched with a clean dry glass rod, or a drop of distilled water be placed upon it, a slightly bitterish sensation is produced; and if the pressure be continued, a feeling of nausea ensues. If a small current of cold air be directed against the tongue, it excites a cool saline taste like that of saltpetre. From the experiments of E. H. Weber, it appears that one of the conditions requisite for the due exercise of the sense of taste is a temperature not departing far on either side from the natural standard. Thus, if the tongue be immersed for a minute in water at a temperature of 125°, or in iced water, the taste of sugar, &c., is no longer perceived. In order that sapid bodies should cause taste, it is necessary that they should be dissolved, and made to permeate the tissue of the papillæ, so as to come in contact with their nerves. This is proved by the two following facts: 1st, that every substance, whether solid, fluid, or gaseous, which possesses a distinct taste, is more or less soluble in the fluids of the mouth, while substances which are perfectly insoluble are only recognised by the sense of touch; and 2d, that if the most sapid substance be applied in a dry state to a dried part of the surface of the tongue, no sensation of taste is excited. Bitters and acids appear to be the most sapid bodies, since they may be diluted to a greater extent than any other known substances without ceasing to excite sensations of taste. Thus, according to Valentin, 1 part of extract of aloes, or of sulphuric acid, in 900,000 of water, and even 1 part of sulphate of quinia in 1,000,000 parts of water, may, with ease, be distinguished from perfectly pure water. 'The contact of a sapid substance,' says Dr Carpenter, 'much more readily excites a gustative sensation when it is made to press upon the papillæ, or is moved over them. Thus there are some substances whose taste is not perceived when they are simply applied to the central part of the dorsum of the tongue, but of whose presence we are at once cognizant by pressing the tongue against the roof of the mouth. The full flavour of a sapid substance, again, is more readily perceived when it is rubbed on any part of the tongue, than when it is simply brought in contact with it, or pressed against it. Even when liquids are received into the mouth, their taste is most completely discriminated by causing them to move over the gustative surface: thus, the 'wine-taster' takes a small quantity of the liquor in his mouth, carries it rapidly over every part of its lining membrane, and then ejects it.'—*Principles of Human Physiology*, 6th ed. p. 621. Most sapid substances affect the nerves of smell to a greater or less degree, as they pass down the throat; and it is this compound of taste and smell that constitutes *flavour*. It is a common habit to hold a child's nose when he is taking a nauseous draught, with the view, as is supposed, of deadening the taste. The efficacy of the process depends upon the exclusion of smell, and the reduction of the flavour of the medicine to its mere taste. The agreeable sensation produced by sipping good wine is due to what is termed its *bouquet*, or, in other words, to its flavour, or combined taste and smell. Some substances leave a taste in the mouth very different from that which they first produced. This *after-taste* is usually bitter; but in the case of one of the most bitter substances known, namely, tannin, it is sweet. This connection seems, in a degree, to correspond to the complementary colours in vision.

There can be no doubt that the sense of taste has for its primary object to direct us in the choice of food, to make the act of eating agreeable, and to excite the flow of mucus and saliva which aid the

digestive process; and amongst the lower animals, the instinctive perceptions connected with this taste are much more remarkable than in man. As a general rule, it is found that those substances whose taste is agreeable are useful articles of food, and *vice versâ;* although there are some well-known exceptional cases. Sir Henry Holland, in his *Medical Notes and Reflections*, observes that in the majority of instances of actual illness, the desires of the patient as to food and drink may be safely complied with, even when some seeming extravagance of diet is suggested; and that in the early stage of recovery from gastric fevers, he has seen many curious instances of such contrariety to all rule acquiesced in with manifest good to the patient. 'Dietetics,' he adds, 'must become a much more exact branch of knowledge, before we can be justified in opposing its maxims to the natural and repeated suggestions of the stomach, in the state either of health or disease.'

TATE, NAHUM, a poet and dramatist, son of the Rev. Dr Faithful Tate, was born in Dublin in 1652, and educated at Trinity College, Dublin. In 1690, he succeeded Shadwell as poet-laureate, and held that dignity till his death in 1715. His habits were somewhat improvident, and in the latter part of his life he resided within the precincts of the Mint at Southwark, then a privileged sanctuary for debtors—hence perhaps that 'down-cast look' and inability to 'say much for himself,' for which, it is said, he was remarkable. His writings include nine or ten dramatic pieces, *Panacea, or a Poem on Tea*, various birthday odes, and an elegy on the death of Queen Mary. He lived to write the first birthday ode for George I. But T. is best known by the metrical version of the Psalms, which he executed in conjunction with Dr Nicholas Brady, chaplain to King William and Queen Mary, which was attached to the Prayer-book, and came into general use in the Church of England, supplanting the older version made in the reign of Edward VI. by Sternhold and Hopkins.

TATIAN, one of the early apologists of Christianity against the pagan philosophers, and the founder of a sect which, whether under his own name, or under various other appellations derived from its peculiar tenets or practices, attracted considerable notice in the primitive ages. T. was born in Syria or Assyria about the year 130. Having cultivated rhetoric and philosophy in various places, he came to Rome about 162, where he became the disciple and friend of Justin the Martyr, and was by him converted to Christianity. He is known to have written many works—*infinita volumina*, says Jerome—of which, however, only one is preserved, the Apology already referred to. The date of its composition is uncertain, but it seems probable that it was written before the death of Justin (166 A.D.). No trace appears in the Apology of the heterodox opinions of T., and it is alleged by Tertullian (*Adv. Hær.* i. 28, 1) that it was not till after the death of Justin that he fell into the errors to which he has given a name. He then removed to the East, and is said to have established himself in Mesopotamia. Without entering into the details of T.'s peculiar opinions, it will be enough to say that, especially in their moral aspect, they form the foundation of one of the great divisions of Gnosticism (q. v.). Starting from the common principle of dualism, and of the origin of matter from the evil principle, and its consequent evil nature, T., unlike the Egyptian Gnostics, held the necessity of overcoming the corrupt nature of man, and purifying it by abstinence and ascetic rigour. Accordingly, he reprobated marriage, and condemned all sensual indulgence. One of his 'opinions,' affirming the damnation of Adam, was peculiarly odious to the orthodox party. He condemned the use of wine so strongly as to forbid it even in the celebration of the Eucharist, in which his followers permitted only water to be used, whence they received the name of *Hydroparastatai* (from *hydor*, water, and *paristemi*, I present), and Latin *Aquarii*. From their generally rigorous asceticism, they were called *Encratites* (from *engkratein*, to keep continent). In their dogmatic views as to Docetism, the Demiurge, and Emanations, they differed little from other Gnostics of the Syrian school. See GNOSTICS, MANICHÆANS, MYSTICISM.

TATIUS, ACHILLES, one of the later Alexandrine authors, of whose life absolutely nothing is known. He was formerly thought to have flourished during the 2d or 3d c. A. D.; but as he undoubtedly imitated the style of Heliodorus of Emesa, he cannot be placed earlier than the beginning of the 6th c. (see NOVELS). Suidas, who calls him Achilles Statius, says that he was originally a pagan, but that he was afterwards converted to Christianity, and rose to be a bishop. If this be true, the romance which has preserved the author's name, *Ta Kata Leukippen kai Kleitophōnta* (The Loves of Leucippe and Cleitophon), must have been composed before his conversion, for it is in parts too licentious and too heathenish to be the work of a Christian, and more especially of a convert. The first edition of the Greek original appeared at Heidelberg in 1601; another, with a copious commentary, was published by Salmasius in 1640; but the best is that by Fr. Jakobs (Leip. 2 vols., 1821).

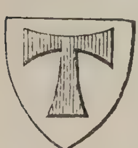
TA'TTA (more correctly, THATTA), a town of Sinde, on the right bank of the Indus, and at the head of the delta of that river, 64 miles east of Kurrachi. In former times, T. was a most flourishing town, and manufactured fabrics of silk and cotton—a branch of industry that has almost wholly disappeared. The only noticeable structure is the mosque of Shah-Jehan, built of brick, which is now falling into decay; but the vast cemetery of T. deserves mention. It has an area of 6 sq. m., contains, it is calculated, at least a million tombs, and has room for not less than four millions. Pop. of T. about 10,000.

TATTOO, in Military life, is the beat of drum and bugle-call sounded at sunset to draw in all stragglers and others on detached duty.

TATTOO'ING, a custom extensively prevalent among savage nations, of marking the skin with figures of various kinds, by means of slight incisions or punctures and a colouring matter. The term is of Polynesian origin, and is said to be derived from a verb *ta*, which signifies to strike. Tattooing is almost universal in the South Sea Islands, except where Christianity and civilisation have put an end to it. New Zealanders' heads, exhibiting tattooing, are amongst the curiosities to be seen in museums; and at one time it was very common for the masters of vessels visiting New Zealand to purchase them and bring

New Zealand Chief's face tattooed.
(From a Photograph.)

them home, although there is too much reason to believe that the price paid for them stimulated the feuds of the natives. The tattooing of the New Zealanders and other South Sea Islanders often covers the whole face, and sometimes also the chest, arms, and other parts of the body with elaborate patterns. It is performed in youth, and marks the transition from boyhood to manhood, like the assumption of the *toga virilis* among the ancient Romans. The operation is accompanied with superstitious ceremonies, and is attended with considerable pain, which, of course, is to be endured with manly indifference. An instrument of bone, toothed on the edge, is employed, which is applied to the skin, and struck with a piece of wood, having first been dipped in a thick mixture made by rubbing down charcoal with a little water. The marks which result are permanent, and appear black on a brown skin; although they are dark blue on the skin of a European. Tattooing is, or has been, practised in almost all parts of the world. It seems to be one of the practices prohibited to the Jews, in Lev. xix. 28, 'Ye shall not make any cuttings in your flesh for the dead, *nor print any marks upon you*,' from which may be inferred its prevalence among the surrounding tribes in the days of Moses, and its connection with their superstitions. The Bedouin Arabs, the Tunguses, and other eastern tribes, and many tribes of American Indians, practise it at the present day. Among the Bedouins, it is a favourite mode of female adornment. It prevailed among the ancient Thracians, and was distinctive of high rank. The ancient Britons also practised it, and traces of it appear to have lingered in England till after the Norman Conquest. Perhaps the practice of sailors to print anchors and other marks on their arms, may be regarded as a relic of it still subsisting.



Tau.

TAU, Cross, in Heraldry, a cross of a form somewhat resembling the Greek letter *Tau*. St Anthony is generally represented with a cross of this description, embroidered on the left side of his garment.

TAUCHNITZ, Karl Christoph Traug., a famous German printer and bookseller, was born at Grosspardau, near Leipzig, in 1761. Bred a printer, he began, in 1796, a small printing business of his own in Leipzig, with which he shortly after conjoined publishing and typefounding, and which, in process of time, became one of the greatest establishments of the kind in Germany. In 1809, he began the issue of a series of editions of the classic authors, the elegance and cheapness of which gave them a European circulation. By offering a prize of a ducat for every error pointed out, he was able to bring out, in 1828, an edition of Homer of extraordinary correctness. He was the first to introduce (1816) stereotyping into Germany; and he also applied it to music, which had not been attempted before. In the latter years of his busy life, he stereotyped the Hebrew Bible, and the Koran in the original Arabic. On his death, in 1836, the business was continued by his son, Karl Christian Phil. Tauchnitz.—A nephew of the elder T., Christian Bernh. Tauchnitz, also set up a publishing establishment in Leipzig, combined with printing. Among the most noted of his undertakings is the issue of 'British Authors' (begun 1842), so well known to all English travellers on the continent, of which upwards of 1000 vols. have appeared.

TAULER, John, a remarkable mystic and preacher, was born at Strasburg in 1290, and died there 16th June 1361. About the year 1308, renouncing a considerable fortune, he entered into the mendicant order of Dominicans, and afterwards studied theology in Paris, shewing at that early period a predilection for speculative and mystic writings, as the scholastic philosophy and the prevailing theology of the schools did not satisfy him. Notwithstanding this tendency, his predominating practical turn of mind led him, on his return to Strasburg, to preaching and pastoral duty; and this he continued to practise with zeal and undaunted courage, even when, in consequence of the excommunication which the pope had hurled against the Emperor Ludwig, the country had fallen into a state of dreadful distraction, and almost all the clergy, in obedience to the interdict issued by the Bishop of Strasburg, had suspended worship. Although T. was now 50 years old, and had enjoyed celebrity for several years as a preacher, so powerfully was he influenced by a Waldensian of the name of Nicholas von Basel, who paid him a visit in 1340, that he gave himself up for two years to ascetic exercises and devout contemplation. Afterwards, however, he betook himself more decidedly to vigorous exertions on behalf of the despised and oppressed people, and preached with wonderful power, inveighing against the avarice, ostentation, and hard-heartedness of the laity as well as of the clergy; and, although not departing from the doctrines of the church, yet fearlessly exposing its abuses, and even not sparing the pope. Thus it happened, that although he had indefatigably administered the consolations of religion in the midst of the horrors and desolation of the Black Death (q. v.), the bishop interdicted him from preaching, and he was obliged to quit his native town. He repaired to Cologne; but nothing further is known, either of his residence there or of his return to Strasburg, where, after a life full of toil, denial of self, and beneficence to others, he died, an old man of 70 years, and was buried in his cloister. If not the greatest German preacher of the middle ages as a whole, T. certainly was the greatest of his times. As his mysticism was in noways passive, but aimed at rising above the sad condition of his times and the failings of the church by inward piety and a love self-denying but at the same time active; so his style, both in his preaching and in his devotional works, was lively, impressive, picturesque, and had altogether a practical direction. Among his devotional works, the *Nachfolge des armen Lebens Christi* holds the first place. Whether the sacred hymns which bear his name really belong to him, is doubtful. Of his writings and sermons, in which he always used the German language, many have been preserved in MS.; and since 1498, numerous editions have been published, but untrustworthy, and often translated into the dialect of the place where they happened to be printed. A careful translation into new High-German has been published by Schlosser (*Predigten*, 3 vols. Frank. 1826; *Nachfolgung des armen Lebens Christi* (Frank. 1833); Schmidt, *Johannes Tauler von Strasburg* (Hamb. 1841); and Susannah Winkworth, *Life and Times of Tauler*, with 25 of his sermons translated from the German (Lond. and New York, 1857).

TAUNTON (*Tone-ton*), so named from being built on the banks of the river Tone, is situated in the extensive and beautiful valley of Taunton Dean, or Vale of Taunton, in the county of Somerset, 37 miles south-west of Bristol by railway. It communicates by railway with the Bristol and English channels. The streets are wide, well-paved, and lighted; the shops are modern and capacious,

There are places of worship connected with the Established Church, 4; Baptists, 1; Independents, 2: Wesleyans, 2; Friends, 1; Plymouth Brethren, 1; Unitarians, 1; Roman Catholics, 1. T. has an Archæological and Natural History Society, in connection with which there is an extensive museum—rich especially in fossils from the Devonian strata, and the bones of mammalia of the cave period from Mendip and the Somersetshire gravels—and a well-conducted reading-room. There is a collegiate school founded by Bishop Fox, 1522, and several other good schools, and many charitable and other institutions. T., which is a parliamentary borough, returns two members to the House of Commons. Pop. (1881) 16,611. Ina, king of the West Saxons, built a castle in T. about 700 A.D.; here, too, he held a great council, in which was drawn up a code of laws for the government of his realm. Ethelard bestowed the town of T. on the church of Winchester. In 1127, Giffard, Bishop of Winchester, built and endowed a priory here for the canons of St Augustine; and in 1322, we find a house here of Carmelite friars, founded by Walter de Meriet, lord of the manor of Combe Florey. In 1269, a leper-house was founded in that part of the town known as East Reach. To T. Castle, Perkin Warbeck fled when he failed in storming Exeter. During the civil wars between Charles and the parliament, the town was twice besieged by Goring, and twice successfully defended by Colonel Blake. In T., Monmouth received the heartiest welcome, and Judge Jeffreys exercised his unbounded cruelty.

TAUNTON, a flourishing town of Bristol County, Massachusetts, on Taunton River, 35 miles south of Boston, and 30 miles E.N.E. of Providence. The falls of Taunton River and its branches furnish water-power to numerous factories, among which are 6 cotton-mills, 1 for cotton machinery, 2 for locomotives, 6 for machinery, 6 foundries, 2 tacks and brads, copper and zinc, 3 britannia ware, with rolling-mills, a nail and shovel factory, metallic gas pipes, enamelled cloth, screws, files, arms, crucibles, fire-brick, &c. In 1865, 2191 tons of tacks and brads were produced, valued at $530,000; and the copper, yellow metal, and zinc factory employed 1875 tons, valued at $1,694,000, and turned out copper-sheets, bolts, printers' rolls, &c., weighing 3,750,000 lbs. Pop. (1880) 21,213. Three railways pass through it, and it has a considerable coasting-trade by the river, and important fisheries of shad, herrings, and alewives. There are 16 churches, 33 schools, a state hospital for the insane with 400 patients, academy, court-house, 1 daily and 3 weekly newspapers, 3 banks, &c. T. was settled from Taunton in England in 1638. Its first minister was William Hooke, afterwards a chaplain of Cromwell.

TAU'NUS MOUNTAINS. See NASSAU.

TAU'RIDA, a government of South Russia, bounded on the E., S., and S.W. by the Sea of Azov and the Black Sea. Area, 24,140 sq. m.; pop. 606,783, mostly Nogai Tartars. The peninsula of the Crimea (q. v.) forms the southern portion of the government, and is connected with the northern portion by the Isthmus of Perekop (q. v.). The region north of the isthmus is flat; the Crimea contains mountain-ranges which rise upwards of 5000 feet. The only great river is the Dnieper, which forms the north-west boundary; and the other principal streams are the Salgir and Alma in the Crimea. Among the salt lakes of the Crimea, which are very productive in salt, the Lake of Sakky is celebrated for the efficacy of its waters in certain cases of disease. The climate is temperate and warm on the southern shores of the Crimea. The soil is fertile, but cultivation is carried on on a very limited scale. In the north, the pasturage is very rich, and cattle-breeding is the main employment of the inhabitants. In the south, the mountains are clad with forests, the tobacco-plant is successfully cultivated, and fruit-growing and wine-culture are the principal occupations. The Crimean wines, the *bouquet* of which resembles that of Burgundy and the Rhenish wines, are of a very good quality. The native riches of the government, its excellent ports and harbours, promise great commercial progress. Simferopol (q. v.), in the Crimea, is the capital of the government, and Sebastopol and Theodosia are ports of rapidly increasing importance.

TAU'RINE, $C_2H_7NSO_3$, is a very remarkable substance occurring in the bile and in other animal products and tissues. In a state of purity, it forms six-sided glistening prisms, which are perfectly transparent, neutral, devoid of odour, readily soluble in hot water, but difficult of solution in cold water, and insoluble in alcohol and ether. It does not enter into combination either with acids or bases. When heated, it undergoes decomposition, and evolves sulphurous acid, in consequence of the sulphur (upwards of 25 per cent.) which it contains. Taurine occurs naturally in the bile of many animals, including man. As a product of the decomposition of the bile, it may be found in the contents of the intestine and in the excrements; and in cases of jaundice it has been found in the blood, transudations, and urine. Its artificial formation has been noticed in the article SYNTHESIS. Its name is derived from the Latin *taurus*, a bull, because taurine was first discovered in the bile of the ox.

TAU'RUS, MOUNT. See ANATOLIA.

TAUTO'G, or BLACKFISH (*Tautoga nigra* or *Americana*), a fish of the family *Labridæ* (q. v.), of the section forming the family *Cyclo-labridæ* of Müller. It is found in the North American seas, and is in great request for the table. It brings a very high price in the New York market. It attains a size of 12 or 14 lbs. Its colour is black on the back and sides; the belly is whitish; both jaws have a double row of strong conical teeth; the face is covered with a scaleless integument. The T. is caught by hook and line on rocky bottoms. It is sometimes kept in stews to fatten.

TAUTO'LOGY (Gr. *tauto*, the same, and *logia*, speech) is a term used to denote the useless repetition of the same ideas in different words. It is considered one of the worst vices, whether of oral or written style, and certainly none more effectually robs language of its force and impressiveness.

TA'VERN, a place of entertainment for man and beast, is not a legal term. See INN, PUBLIC-HOUSES.

TAVERNIER, JEAN BAPTISTE, BARON D'AUBONNE, a celebrated French traveller, was the son of a Flemish engraver who had settled in Paris, and was born there in 1605. The conversation of the savans who frequented his father's shop inspired him with an ardent curiosity to visit other countries, and prompted him to leave the parental roof before his 15th year. After visiting England, the Low Countries, Germany, Hungary, and Italy, he eagerly caught at the offer made to him by Father Joseph (the confidant of Richelieu), to accompany two French noblemen to the East. This journey lasted from December 1630 to the summer of 1633, the line of route passing through Regensburg, Dresden, Vienna, Constantinople (where he left his masters), Erzeroum, Tabriz, Ispahan, Bagdad, Aleppo, and Scanderoon, and thence by sea to Rome. T. then obtained an important post in the household of the Duke of Orleans, but received occasional leaves of absence to prosecute his journeys in the East. The *second journey* (1638—1643) was from Marseille

to Scanderoon, thence across Syria to Ispahan, South-western Persia, and Hindustan; the *third* (1643—1649), through Ispahan, much of Hindustan, Batavia, and others of the East Indies; and in the *fourth* (1651—1655), *fifth* (1656—?), and *sixth* (1663—1669), various portions of Persia and Hindustan were visited, the outward route being generally by way of Syria and the Arabian Desert, and the return one by Asia Minor. T. invariably travelled as a dealer in precious stones and other valuable articles of small bulk, and the great profits he realised strongly impressed upon him the advantages of regular commerce between Europe and the East. On his return to France in 1669, he was graciously received at court by Louis XIV., who presented him with 'letters of nobility' in reward for his services to French commerce in India. But his prodigal expenditure and careless generosity speedily reduced his fortune, and the revocation of the Edict of Nantes compelled him to take refuge in Switzerland, whence he removed to Berlin, and became director of an East India Company which was projected by the Elector of Brandenburg. With the view of discovering a road to the Indies through Russia, he set out from Berlin in 1688, but died at Moscow in July 1689. An account of his travels was written for him by various parties (for T. had no literary qualifications), and though full of matter valuable to the historian and geographer, it is so ill-arranged as to be in many cases almost unavailable. T. was one of the most remarkable of travellers; wholly devoid of classic sentiment, he traversed the plains of Troy, and passed the ruins of Persepolis without even a flutter of interest, and partly owing to this remarkable condition of mind, his statements are distinguished by an accurate truthfulness little common among travellers. But the chief value of his book lies in the fulness and accuracy with which the nature and state of oriental commerce, the chief markets and commercial routes, and the various systems of coinage and their relations are detailed. Some of his statements concerning the conduct of the Dutch in the East Indies called forth a most virulent and abusive reply from Jurieu, the Protestant theologian, in his *L'Esprit de M. Arnauld* (1684), and a more moderate one from Van Quellenburgh; but all T.'s assertions which were of any moment were found to be perfectly correct. His Travels were originally published in 3 vols. (two in 1676—1677, and the third in 1679); they have since been several times republished, last in 1810, in 7 vols.; and have been translated into English, Dutch, and German.

TAVIRA, Portugal. See SUPPLEMENT in Vol. X.

TA'VISTOCK, a parliamentary borough and market-town of Devonshire, picturesquely situated on the western border of Dartmoor, about 35 miles south-west of Exeter, in the fertile valley, and on the right bank, of the Tavy (whence its name), which is here crossed by two bridges within the town. T. is a thriving town, with some small manufactures of serges and woollen cloths, iron-foundries and mining-works, copper, lead, tin, and iron being found in considerable quantity in the neighbourhood; but the population is chiefly agricultural. It is a place of considerable antiquity, and was formerly of great importance, owing mainly to its abbey, the largest and most magnificent in Devonshire, which was founded in the year 961, for the Benedictine order, by Ordgar, Earl of Devonshire, father of the infamous Elfrida, and endowed with many privileges, the abbot, in the early part of the reign of Henry VIII., being admitted to the peerage. At the dissolution, in the same reign, when the revenue amounted to upwards of £900, it was bestowed upon John Lord Russell, in possession of whose descendant, the Duke of Bedford, the property still remains. A printing-press, the second set up in England, was established in the abbey at a very early period. Some remains of the ancient buildings still exist in the town. The parish church is a handsome edifice, with a tower at the west end, resting on arches, under which there is a thoroughfare. The borough has returned two members to parliament since the year 1295: at the breaking out of the Great Rebellion, Pym was one of the members. T. is one of the four stannary towns of the county, and is governed by a port-reeve, elected annually; a county court is held in the town. It is connected with Launceston and Plymouth by railway, and with the river Tamar by a canal, completed in 1817. Sir Francis Drake was born in the immediate neighbourhood in 1545, and the poet W. Browne in the town in 1590. Pop. (1881) of parliamentary borough, 6909.

TAVOY', the chief town of the province of Tavoy (see TENASSERIM), is situated on the left bank of the Tavoy River, about 34 miles from its mouth, in N. lat. 14° 4', E. long. 98° 5', at the distance of about 220 miles south of Maulmain. The site of T., which is low, is enclosed on three sides by rice-fields, and on the fourth by the river. The houses are scarcely visible from the river—umbrageous trees, palms, plantains, jacks, cassias, and hundreds of flowering shrubs nearly concealing them from view. A wooden-covered pier, supported on piles, forms a convenient landing-place. There is a hospital, a large jail, and a roomy *zayat*, or caravansary. The houses, according to the universal practice of the country, are raised from the ground on piles, and are made of bamboo, fastened with rattan, and thatched with the leaf of the water-palm. Under many of the houses, a loom may be observed, at which a female is generally busy at work. The shops are for the most part mere sheds or stalls, and the vendors sit squatted on the raised floor in the midst of their wares. 'In this little town,' says a recent eye-witness, 'Burman life and manners are seen in all their simplicity; and the observer cannot but be struck by the frugality, contentment, happiness, and enjoyment of life manifested by the people.' T. is remarkable for its grand annual buffalo-fight. The sport continues for two days, and during that time eight pair of buffaloes are brought into the field, each animal representing a different district or township. The rice-fields around T. are prolific sources of malaria. Intermittent fevers and dysentery are the most common diseases; but the climate is on the whole healthy, and is not considered inimical to the European constitution. According to the estimates of 1871—1872, the pop. of T. was 14,467. The bulk of these are true Burmans, the balance being made up with Shans and Thoungthoos, Karens, Chinese, Malays, and natives of India.

Vessels drawing not more than 12 feet of water can reach the town of T. by means of the Tavoy river. The anchorage for large ships is at Goodridge Plains, about 30 miles below the town.

Tavoy used to be one of the stations in which British troops were settled, but these have been lately withdrawn.

TAX, TAXATION. This term, as expressing the exaction of money from the individual for the service of the state, is familiar to all mankind a step above barbarism; and yet few subjects are surrounded by a greater number of practical difficulties and theoretical niceties. These may be grouped under two sets of considerations—those which affect the justice of a tax, and those which affect its productiveness, and these two often tell on each other. Taxation, indeed, has so frequently been the

means of perpetrating political injustice, that the term has fallen into bad popular repute. Whenever the produce of a tax is used otherwise than in the service of those who pay it, the tax is unjust. In its more oppressive form, it has been levied on conquered states, for the benefit of the conquerors, and in this shape it has sometimes been called tribute. The direction which all constitutional struggles to cleanse taxation from injustice have taken has been that of self-taxation, the community as a whole deciding on what it requires to take from the individual members for the public service. The accomplishment of this has been the chief object of all the struggles which have made a free constitution for the British Empire. There were old feudal dues which the monarchs had the power of exacting; but when these were insufficient for their ambitious projects, they had to ask parliament for a supply, and parliament generally took the opportunity of granting it to demand redress of grievances. It came thus to be a fundamental constitutional doctrine, that no tax can be levied save by the consent of the representatives of the people who have to pay it. The constitutional doctrine thus created by Britain was remembered by the American colonies when Mr Grenville sought to raise there a stamp-duty and a customs-duty on tea, and the colonies revolted under the celebrated cry that 'Taxation without representation is tyranny!'

It was discovered, in the course of the long struggle of the House of Commons to keep its hold on the purse, that the least afflictive of taxes may be the most dangerous. A fixed land-tax comes, for instance, to be no impost at all, in the afflictive sense of the term. If a thousand a year has been drawn off a certain acreage of land from time immemorial, the proprietors never possessed that part of the rents, and are no more sufferers from not having them than from not possessing their neighbours' estates. A government with a large revenue of this kind, however, will certainly be inimical to freedom. The time when the liberties of England were in the greatest danger was the twelve years of Charles I.'s reign in which he was able to get on without going to parliament for money. The extravagance of sovereigns who wasted the domains of the crown has generally prevented them from having too formidable an influence by the possession of independent incomes. In Britain, this difficulty has been effectually guarded against, and any of the expenses of the crown which can now be paid without going annually to parliament for a vote of supply are of a very trifling character.

How to make taxation productive, is a vast and complicated practical science. Turgot, one of the wisest of financiers, called it the art of plucking the goose without making it cry. The most ingenious devices to this end, however, have often, in practice, met with counteracting difficulties. It was supposed that indirect taxation—that is, a duty levied on articles before they reach the consumer, must, in a civilised and orderly country, be almost inexhaustible. The merit of the system lay in the consideration, that the burden of the tax did not fall on the person who paid it. Income-tax, house-tax, dog-tax, and the like are levied directly on the person on whom the burden ultimately falls, and if he do not pay, the amount will be taken by force. Tea-duty, sugar-duty, and wine-duty, however, are not levied on the consumer, though he has to pay them; they are levied on the importer, who has no, or a very slight, interest against the tax, since he must charge it on the consumer. But this form of taxation is met by checks. If it is excessive, people will not buy the taxed article; and it has often been found that reducing the duty increases the revenue. An indirect tax on luxuries, and especially on those which may be used to vicious excess, has strong recommendations. In some cases, it is no great calamity should the tax throw the article nearly out of use. But then comes another check in the smuggler, whose profession may probably do more to corrupt and disorganise society than the free use of the article in which he deals. A tax on the necessaries of life, on bread or salt, cannot be evaded, as in the case of luxuries, by the abandonment of use, and therefore it is very productive, but it is also very oppressive. The tax on salt in France was one of the chief causes of the French Revolution. The happiest condition for the revenues of a country is when luxuries are so abundantly used by all classes that a small addition to their price is a slight burden, yet yields a large revenue. In this country, the revenue thus derived from tea, sugar, and stimulants may be set down in round numbers at 30 millions. The chief taxes which now form the revenue of Britain are—1. Those by old custom called 'assessed,' and levied upon certain items in the possessions and enjoyments of the citizen, as his house-domestics, horses, dogs, and armorial bearings. 2. The property and income tax, which, after long disuse, was renewed in 1842, and is raised from time to time according to the exigences of the government. 3. The customs. 4. The excise. 5. The stamps and post-office; and 6. The land-tax. See CUSTOMS DUTIES, EXCISE, POST-OFFICE, STAMPS, LAND-TAX, FINANCE.

TAXA'TION OF COSTS is the checking or reviewing of the charges made by attorneys or solicitors for legal business; and there is an officer of the court provided for the purpose, called in England a master or a taxing-master, or a registrar, according to the nature of the court; in Scotland, he is called an auditor. Solicitors differ from all other professions in this, that they are treated as officers of the court, and they are not at liberty to charge what prices they please for the various services they perform. Hence, every step in a suit has a certain value put upon it by the court, and the business of the taxing-officers is to see that this standard is not trangressed. There are many exceptional matters, however, which arise in every suit, which often cause difficulty in apportioning a proper amount of remuneration, the taxing-officer having a considerable discretion. In consequence of a taxing-officer being provided by the court, it is a right which every client of a solicitor has, if not satisfied with the bill of costs delivered to him, to have it referred to the taxing-officer to be taxed. But in general, this must be done without delay. If the taxing-officer certify that more than one-sixth too much has been charged, then not only is the client not bound to pay the excess, but the expense of the taxation must be borne also by the solicitor; whereas if less than one-sixth is taxed off, the client has to bear the expense of taxation. Not only are the expenses of a suit liable to taxation, but other kinds of miscellaneous business which a solicitor does as a solicitor. It has often of late been made matter of complaint that solicitors are not allowed to fix their own charges, or to agree with clients upon an arbitrary charge, or a charge by commission, the tendency of the present system being to make the solicitor anxious to eke out his remuneration by lengthening the proceedings, so as to make a basis for chargeable items; but the legislature has steadily rejected hitherto all attempts to abolish the check provided by taxation.

TAXEL. See BADGER.

TAXICO'RNÉS, a family of coleopterous insects, of the section *Heteromera*, having the body

generally square; the thorax either concealing or receiving the head; the antennæ short; the legs adapted for running. Most of them are found in fungi and beneath the bark of trees. They are widely distributed over the world.

TA'XIDERMY, the art of preparing the skins of animals for the purposes of the naturalist. The chief means employed in preparing the skin for stuffing in the case of small animals is to remove it carefully from the body, and, having cleaned away from it any adherent flesh, &c., to anoint it with arsenical soap; for the making of which there are several formulæ, the following being the most used: arsenic, 1 ounce; white soap, 1 ounce; carbonate of potash, 1 drachm; distilled water, 6 drachms; camphor, 2 drachms. This keeps the skin supple, and prevents decay and the attacks of insects. The larger skins are generally prepared with a composition called Preservation Powder, which is made of the following ingredients: Arsenic and burnt alum, each 1 lb.; powdered oak-bark, 2 lbs.; camphor, ½ lb. These substances are all reduced to a powder, mixed, and passed through a fine sieve. It requires to be carefully kept in well-stoppered bottles or jars, and when used, is thickly sprinkled over the flesh-side of the skin whilst still wet, and must be thoroughly rubbed in. Gloves should always be worn in this process, to prevent danger from the poisonous compound. Some skins are prepared with alum only, and others with the oak-bark liquor of the tanner's pits. This, in the case of very large skins, answers very well.—Besides the mere preparation of the skin, the art of taxidermy is held to mean also the stuffing and mounting of them. This requires much personal experience, and as almost every group of animals must be treated differently, it is impossible to explain the various methods fully in this short notice. Various works have been written upon the subject.

TAY, the largest river in Scotland, draining nearly the whole of Perthshire (q. v.), and pouring into the German Ocean a greater bulk of water than any other British river, has its source in the western part of the county of Perth. The Dochart, the principal feeder of Loch Tay, rises in Ben Lui, on the borders of Argyleshire, and flowing in a north-east direction, is joined by the Lochy, just before the united streams enter the lake. After leaving it, the Tay flows for some distance east-north-east, when turning southwards it passes, with a very winding course, Dunkeld (q. v.) and Perth (q. v.); about a mile below the latter place, it again changes its direction to east-north-east, widening at the mouth of the Earn (q. v.) into an estuary—the Firth of Tay—which varies from three-fourths of a mile to three miles in breadth, and lies mostly between the counties of Fife and Forfar, joining the German Ocean about ten miles below Dundee (q. v.). From the north and east, the Tay receives the Lyon, the Tummel and Garry, and the Isla; and from the west, the Almond and the Earn; its entire basin comprises an area of about 2500 square miles. The salmon-fishings on the Tay and its tributaries are of considerable value. The Stormontfield ponds for the propagation of salmon are 5 miles above Perth. The tide flows up the river to about a mile above Perth, to which place it is navigable by vessels of 100 tons; and to Newburgh, about 20 miles from its mouth, by vessels of 500 tons; the navigation up to Dundee, notwithstanding the many precautions which have been taken, is attended with very great difficulty, on account of the numerous and shifting sand-banks.

LOCH TAY is a long and narrow lake, picturesquely situated in a basin scooped out of the bosom of the mountains, 355 feet above the sea-level, in length about 15 miles, and average breadth 1 mile, varying from 100 to 600 feet in depth. Ben Lawers (q. v.) lies on its west side. The loch is at times subject to violent and unaccountable agitations.

TAYLOR, BAYARD, an American author and traveller, born at Kennett Square, Chester County, Pennsylvania, January 11, 1825. Having received a common school education, he was apprenticed at 17 in a printing-office, and at the same time began his poetical contributions to periodicals; and in 1844 he published a volume of poems under the title of *Ximena.* Soon after, with a small fund from this and other sources, he started on a pedestrian tour of Europe, and in 1846 published *Views Afoot, or Europe seen with a Knapsack and Staff.* After his return, he spent a year editing a country newspaper in Pennsylvania, when he went to New York, and wrote for the *Literary World* and *Tribune.* Of the latter, he became assistant-editor and shareholder in 1849, and in the interests of that journal, as its correspondent, made extensive travels in California and Mexico, recorded in *El Dorado, or Adventures in the Path of Empire,* 1850; up the Nile to lat. 12° 30′ N., and in Asia Minor, Syria, across Asia to India, China, and Japan—recorded in his *Journey to Central Africa, Lands of the Saracen,* and *Visit to India, China, Loo-Choo, and Japan,* 1853. His later explorations are recorded in *Northern Travel, or Summer and Winter Pictures of Sweden, Denmark, and Lapland,* 1856; and *Travels in Greece and Russia, with an Excursion to Crete,* 1857. During this life of travel and authorship his best writings were in verse. In 1848, he published *Rhimes of Travels, Ballads, and other Poems;* in 1851, *Book of Romances, Lyrics, and Songs;* in 1854, *Poems of the Orient;* in 1855, *Poems of Home and Travel;* in 1859 and 1862, *At Home and Abroad,* and edited a *Cyclopædia of Modern Travel; Hannah Thurston,* a novel, 1864; *Story of Kennett,* and *Picture of St. John,* 1866; *John Godfrey's Fortune,* and a translation of Goethe's *Faust,* in 1870; *Joseph and his Friend,* 1871; *The Mosque of the Gods,* 1872; and *Egypt and Iceland,* 1874. He was appointed U. S. minister to Berlin, where he died Dec. 19, 1878.

TAYLOR, BROOK, a celebrated English mathematician, was born at Edmonton August 18, 1685, entered St. John's College, Cambridge, in 1701, at a time when mathematical science was the prominent pursuit among the learned, took his degree of LL.B. in 1709, became a Fellow of the Royal Society in 1712, and its secretary in 1714, in which latter year he also took the degree of LL.D. Though so young, he had become widely known in Britain and on the continent for great proficiency in mathematical knowledge, and power and versatility of mind, having already written various valuable treatises on capillary action, on the vibration of a string, on music, &c. In 1716, he visited Paris, and was received with warm demonstrations of regard by the French savans, who respected his ability and learning, and the prominent and distinguished part he had taken in the Leibnitzian controversy. On his return to England in 1717, he resumed his habits of severe study, but was forced by declining health to resign the secretaryship in 1718. For the next three years he wandered about, residing now on the continent, now in England. He died, December 29, 1731, at the age of 46. Besides his earlier works above mentioned, he contributed a series of able papers on higher algebra, dynamics, and general physics, published separately his *Methodus Incrementorum* in 1715, and a *Treatise on Linear Perspective,* the first general exposition of this subject, in 1719. During the last ten years of his life

he gave himself up almost entirely to metaphysical and biblical studies. His *Methodus Incrementorum* contains, besides the famous 'theorem' (see TAYLOR'S THEOREM), the first germs of the calculus of finite differences, various now common forms of infinitesimal series, with mechanical, physical, and algebraical applications. The chief use made by T. of his theorem is in a paper (1717) entitled 'Method of Approximation to the Roots of Equations.' The results of his investigations may be found in the *Phil. Trans.* (1713—1723), and in his two works above mentioned.

TAYLOR, ISAAC, born at Lavenham, in Suffolk, 1787, died at Stanford Rivers, in Essex, 1865, eminent as a Christian philosopher, artist, and mechanician, was the third of his name who attained distinction—his grandfather and father (known as Isaac Taylor of Ongar) being both named Isaac, and each in his way distinguished. His eldest son, also named Isaac, has given promise in his *Words and Places* that he will promote the credit of the family name. Charles Taylor, the editor of 'Calmet;' Jane Taylor, author of the Q. Q. papers, and joint-author with her sister, Ann—Mrs Gilbert of Nottingham, who died in 1866—of *Hymns for Infant Minds*, belong to the same talented family. The literary career of Isaac T. extended over nearly half a century. It began in 1818, in contributions to the *Eclectic Review*, for which Robert Hall, John Foster, and Josiah Conder then wrote, and ended in 1865, in contributions to *Good Words*, in which the name of the veteran figured with those of men who were unborn when he was in the height of his reputation. Between 1822 and 1827, he published *Elements of Thought; Characters of Theophrastus*, with illustrations, etched by himself; *The History of the Transmission of Ancient Books to Modern Times*, *The Process of Historical Proof*, a translation of Herodotus, and the *Memoirs and Correspondence of Jane Taylor*, his sister, who has already been mentioned. In 1829, he published, anonymously, *The Natural History of Enthusiasm*, which ran rapidly through several editions; and between 1829 and 1836, he published in succession *Fanaticism*, *Spiritual Despotism*, *Saturday Evening*, and *The Physical Theory of Another Life*. In 1836, appeared *Home Education*. Thereafter, he was a long time occupied upon a new translation of Josephus, undertaken jointly with the Rev. Dr Traill, and which was illustrated by etchings executed by himself. Within the last thirteen years of his life appeared *Loyola*, *Wesley*, *The Restoration of Belief*, *Logic of Theology*, *Ultimate Civilisation*, and *The Spirit of Hebrew Poetry*. Besides these numerous works, Isaac T. wrote many articles for the graver quarterly reviews, which are as yet uncollected. He had been educated as an artist, and some of his designs, executed before he betook himself chiefly to literature, have evoked the warmest praise from the most scrupulous critics, who have wondered how one with such a genius for art could have deserted it. It would be impossible to give here any account that would be intelligible of his numerous mechanical inventions; it must suffice to say, that, by two of his inventions, he revolutionised the art of calico-printing. As is too often the case, the profits of his discoveries have been and are being reaped by others. Isaac T. married in middle life, and had a large family, whose home education, as liberal-minded but pious Christians, was among, and not one of the least of, the tasks of his life. Two incidents connected with the work with which his name is most popularly associated—viz., *The Natural History of Enthusiasm*—may be mentioned in concluding this brief notice. Sir James Stephen wrote an able article in the *Edinburgh Review*, being an imaginary biography of the anonymous writer; and seven years after the publication, Dr Chalmers publicly called upon the author to declare himself, and come forward as a candidate for the chair of Logic in the university of Edinburgh. The flattery of this challenge could not be resisted. Isaac T. declared himself, and became a candidate for the chair, which he nearly won. He was beaten by Sir William Hamilton, whose local influence gave him a small majority of the electors.

TAYLOR, JEREMY, one of the greatest names in the English Church, was the son of a Cambridge barber, and was born in that town, August 15, 1613. At the age of 13, he entered Caius College as a sizar, and after seven years' strenuous and brilliant study in classics and theology, took the degree of M.A. Like Archbishop Usher, he was admitted to holy orders before he had reached his 21st year. Soon after, he attracted the notice of Laud (who had a regard for learning, if none for liberty), and was preferred by him to a fellowship at All Souls, Oxford (1636). About the same time, he was appointed chaplain in ordinary to the king; and in 1638, rector of Uppingham, a preferment which he retained till the successes of the Parliamentarians deprived him of it. The first notable publication of T.'s was a defence of the church, entitled *Episcopacy asserted* (Oxford, 1642). It procured for him the honour of D.D. During the next three years, T. probably accompanied the royal army; but when fortune had unmistakably declared against the king, he withdrew into Wales (1645—1646), and, in conjunction with Mr W. Wyatt of St John's College, Oxford, opened a school at Newton, in Caermarthenshire. It appears to have been a pretty successful adventure, and many of his scholars, we are told, 'having, as it were, received instruction from this prophet in the wilderness, were transplanted to the universities.' T. also found a patron in the Earl of Carbery, who was then living at the family seat of Golden Grove, in the same county, and who appointed him his domestic chaplain. But if this period of T.'s life had become to the outward eye obscure and mean, it is rendered illustrious by the splendour of his literary achievements. Between 1647 and 1660, the long 13 years of his enforced seclusion, appeared all his great works, and remembering their unsurpassed merits, we are almost disposed to feel grateful to those who expelled him from his rectory, and drove him to strictly literary pursuits. In 1647, was published the *Liberty of Prophesying*, a work written on behalf of the clergy of the Church of England, who were being expelled from their livings by the victorious Puritans, but in which the pleadings are based on principles far more comprehensive and tolerant than the age was disposed to acknowledge; in 1650, the *Life of Christ* (2 vols.), one of the most popular of his productions, and *The Rule and Exercises of Holy Living;* in 1651, *The Rule and Exercises of Holy Dying*, a portion of his *Sermons*, and the *Discourse of the Divine Institution, Necessity, and Sacredness of the Office Ministerial;* in 1652, a *Discourse on Baptism, its Institution, and Efficacy upon all Believers;* in 1653, 25 additional *Sermons;* in 1654, *The Real Presence and Spiritual of Christ in the Blessed Sacrament;* in 1655, *The Guide of Infant Devotion, or the Golden Grove*, and the *Unum Necessarium, or the Doctrine and Practice of Repentance*, a decidedly Pelagian treatise, which involved him in a considerable controversy; in 1657, a *Collection of Polemical and Moral Discourses*, a *Discourse on Friendship*, &c.; and in 1660, his famous *Ductor Dubitantium, or the Rule of Conscience in all her General Measures*, the most learned, subtle, and curious of all T.'s

works. It was dedicated to Charles II. T. was a stanch royalist, a splendid scholar, a consummate theologian, and a man of wonderful literary genius, and so it was in the nature of things almost impossible that he should escape preferment. Before 1660 had expired, he was elevated to the bishopric of Down and Connor, a dignity which he only retained some seven years, dying August 13, 1667. T. was not happy in his Irish see. Before a year was over, he was anxious to be delivered from it as from 'a place of torment.' The Scotch Presbyterian ministers were 'incendiaries'—they robbed him of the 'people's hearts;' they even 'threatened to murder' him; his only hope was in the government and the military. Altogether, it is a melancholy spectacle to behold the finest ecclesiastical genius of the time half broken-hearted by petty squabbles with intolerant fanatics, who had, nevertheless, in the points at issue between them and T., something like justice on their side. No modern mind would hesitate for an instant to acknowledge that the Scoto-Irish Presbyterian clergy were perfectly entitled to act as they did, and yet we fear it is too plain that the good bishop would have gladly seen them prohibited by an Episcopalian soldiery. Nay, the author of the *Liberty of Prophesying* went a step further; and on one occasion, only three months after his consecration, actually deposed 36 Presbyterian ministers occupying livings which the Restoration had inconsiderately and tyrannically declared to be Episcopalian. Some very interesting information in regard to this all but unknown period of T.'s life is to be found in *Notes and Queries* (November 11, 1865).

T., sometimes styled the modern Chrysostom (q. v.), on account of his golden eloquence, has no equal in the whole series of ecclesiastical writers for richness of fancy. All other divines—patristic, medieval, and modern—shew poor and meagre beside him in this respect. Some are more logical, or penetrating, or profound; some grasp more clearly the spiritual significance of doctrine, or display a deeper knowledge of human nature; but T. ranks among the first men of his age in point of learning, subtlety of argument, elevation of devout feeling, and philosophic largeness of view, while his inexhaustible imagery, shining 'like the glossy purples of a dove's neck,' and full of all tender and pathetic beauty, reminds us of Spenser and Shakspeare, of Sidney and Fletcher, rather than of the sombre order of theologians.—The best edition of T.'s works is by the Rev. C. P. Eden, M.A., Fellow of Oriel College, Oxford (10 vols., London, 1854).

TAYLOR, Zachary, twelfth President of the United States, was born in Orange County, Virginia, November 24, 1784, son of Colonel Richard Taylor, an officer of the War of Independence, and one of the first settlers of Louisville, Kentucky, where T. was taken in early childhood, and grew up to his 24th year, working on a plantation, with only the simplest rudiments of education. His elder brother had received a lieutenancy in the army, and died in 1808, when T. was appointed to the vacant commission. In 1810, he was promoted to a captaincy; and in 1812, with 50 men, two-thirds of whom were ill of fever, he defended Fort Harrison, on the Wabash, against a large force of Indians led by the famous chief Tecumseh. Promoted to the rank of major for his gallantry, he was employed during the war in fighting the Indian allies of Great Britain. In 1822, he built Fort Jesup; in 1832, he served as colonel in the Black Hawk War; and in 1836, was ordered to Florida, where he gained an important victory over the Seminole Indians at Okechobee, for which he was appointed brigadier-general, and made commander of the United States forces in Florida. In 1840, having been appointed to the command of the south-western department, he purchased an estate at Baton Rouge, Louisiana. On March 1, 1845, the United States Congress passed the resolution for the annexation of Texas, formerly a province of Mexico, and for some time an independent republic. Texas claimed the Rio Grande for her south-western boundary; Mexico insisted that there could be no claim beyond the Nueces, and prepared to defend the disputed, if she could not reconquer the whole, territory. General T. was ordered to Corpus Christi, which point he occupied in November with a force of 4000. On March 8, 1846, he moved towards the Rio Grande, across the disputed territory, and built Fort Brown, opposite and commanding the Mexican port of Matamoras. General Ampudia, the Mexican commander, demanded that he should retire beyond the Nueces, pending negotiations; and on the refusal of General T., his successor, General Arista, crossed the Rio Grande with a force of 6000. On May 8, he was defeated at Palo Alto by General T., with a force of 2300; and a few days after, driven from a new position at Resaca de la Palma across the Rio Grande. War was declared by Congress to exist by the act of Mexico; 50,000 volunteers were called for, T. made major-general, reinforced, and ordered to invade Mexico. On September 9, with 6625 men, he attacked Monterey, which was defended by about 10,000 regular troops. After 10 days' siege and 3 days' hard fighting, it capitulated. General Scott having been ordered to advance on the city of Mexico by Vera Cruz, withdrew a portion of the troops of General T., leaving him only 5000 volunteers and 500 regulars, chiefly flying artillery, to meet an army of 21,000, commanded by President Santa Anna. He took a strong position at Buena Vista, fought a desperate battle, and won a decided victory. This victory, against enormous odds, created the utmost enthusiasm; and General T., popularly called 'Old Rough and Ready,' was nominated for President of the United States over Henry Clay, Daniel Webster, and General Scott; and this 'ignorant frontier colonel, who had not voted for forty years,' and was a slaveholder, was triumphantly elected, over General Cass, the democratic, and Martin Van Buren and Charles Francis Adams, free-soil candidates. Entering upon the presidency in 1849, he found a democratic majority in Congress, with a small but vigorous free-soil party holding the balance of power, while the most exciting questions connected with the extension of slavery, as the admission of California, the settlement of the boundaries of Texas, the organisation of the newly-acquired Mexican territories, &c., were agitating the country, and threatening a disruption, postponed by the compromises introduced by Mr Clay. Worn down by the unaccustomed turmoil of politics, the rough, good-natured old soldier did not long enjoy his honours. One year and four months after his inauguration, he was attacked with bilious colic, and died July 9, 1850.

TAYLOR'S THEOREM, so called from its discoverer, Dr Brook Taylor (q. v.), is a general method for the algebraic development of a function of a quantity, x, in powers of its increment h, and may be thus briefly explained and illustrated. Let $f(x+h)$ denote *any* function of $x+h$ (subject to the limitations below), then $f(x+h) = f(x) + f'(x)h + f''(x)\frac{h^2}{1.2} + f'''(x)\frac{h^3}{1.2.3} + \ldots$, where $f(x)$ is the same function of x, as $f(x+h)$ is of $x+h$, and $f'(x), f''(x)$, &c., are the first, second, &c., differential coefficients of $f(x)$. By a supplementary theorem, due to Lagrange, who was the first to

appreciate to the full the value of Taylor's discovery, it was shewn that the sum of all the terms of the series after n terms, could be represented by $f^n(x+\theta h)\frac{h^n}{1.2\ldots n}$, where θ is some positive fraction less than unity. The theorem supposes that between certain limits, indicated by $h = o$, and h = some finite quantity, neither $f(x)$ nor any of its derived functions vanish, or all of them do not become infinite; and the cases in which these conditions are not satisfied are often spoken of as instances of the 'failure of Taylor's theorem.' An important particular case of this theorem, known as *Maclaurin's*, or (more properly) *Stirling's Theorem*, was independently discovered; it is that case of the general theorem in which the various functions of x are made functions of zero, and is written $f(o+h) = f(o)+f'(o)h+f''(o)\frac{h^2}{1.2}+$, &c. The best illustrations of these theorems are the binomial, exponential, logarithmic, and circular series; thus, if the function be $(x+h)^n$, then $f(x) = x^n$, $f'(x) = nx^{n-1}$, $f''(x) = n(n-1)x^{n-2}$, &c.; and by substitution of these values we obtain Newton's *binomial* theorem; if the function be a^{x+h}, Taylor's series gives us as its equivalent $a^x(1+h\,.\log.\ a+\frac{h^2}{1.2}(\log.\ a)^2+\ldots.)$; and Maclaurin's gives $a^h = 1+h\ .\ \log.\ a+\frac{h^2}{1.2}(\log.\ a)^2+\ldots.$, which latter is the *exponential* theorem, and may be obtained from Taylor's series by division; if the function be log. $(1+x+h)$, (log. $x+h$ being one of the cases in which Taylor's theorem fails), then Maclaurin's series gives the *logarithmic* theorem, log. $(1+h) = h-\frac{h^2}{2}+\frac{h^3}{3}$,—, &c.; and the same theorem gives the various series expressing the values of sin. h, cos. h, sin. ^{-1}h, &c. &c. The history of this celebrated theorem is remarkable. On the first publication of the *Methodus Incrementorum*, it was entirely neglected by Leibnitz, who, in ignorance of its value, severely criticised the whole work; while the bitter hostility of John Bernouilli to British men of science, blinded him to the existence of any merit in any part of the work. The theorem never appeared in any of the works on the calculus published before D'Alembert's *Recherches*, and after that, was given only in the French *Encyclopædia;* but neither D'Alembert nor Condorcet seems to have known that it was Taylor's, or to have fully appreciated its importance; and it was not till Lagrange, in the *Berlin Memoirs* for 1772, gave the name of its true author, and proposed to make it the foundation of the differential calculus, that it assumed that important position which it deserved to hold.

TCHAD, or TSAD, LAKE, a large lake in Sudan, Northern Africa, lat. 12° 30′—14° 30′ N., long. 13°—15° 30′, is bounded on the N. by the kingdom of Kanem, and on the S. by those of Bagirmi and Bornu. It is 200 miles—by some accounts, upwards of 300 miles—long, 170 miles broad, and has an elevation of 800 feet above sea-level. The shores are low, and for the most part unattractive; and a strip of swampy ground surrounds the fine open sheet of water which is the actual T., and the margin of which is lined by papyrus and tall reeds, of from 10 to 14 feet in height. Its depth in ordinary years is from 8 to 15 feet, but in some years the waters rise much higher; and of the islands, of which there are many densely peopled, only the more elevated afford shelter to the inhabitants. River-horses and crocodiles swarm in the lake, and fish and water-fowl are abundant. The banks are infested by a tribe called the Budduma or Jedina, who live by piracy. The inhabitants are black or dark-brown, have regular features, and are decently clothed. From the north, the Waube, a river 400 miles in length, enters the lake; and from the south, the Shari, which in its lower course is upwards of 1800 feet broad. The T. has no outlet, according to Dr Barth, and its waters are perfectly fresh. Dr Overweg spent six weeks in exploring the islands of the lake, and he died and was buried on its banks.

TCHERKA'SK, STAROI (Old Tcherkask), a town of South Russia, formerly the capital of the country of the Cossacks of the Don, stands on the right bank of the Don, 12 miles south of New Tcherkask (see NOVOTCHERKASK), the present capital. Pop. 5278.

TEA (*Thea*), a genus of shrubs of the natural order *Ternstrœmiaceæ*, very nearly allied to the genus *Camellia* (q. v.), and distinguished from it only by the not deciduous calyx, and by the dissepiments remaining connected in the centre of the capsule after it opens. The genus seems to derive its importance entirely from a single species, the dried leaves of which are the tea of commerce, one of the most important articles of commerce in the world, and yielding the most esteemed and extensively used of all non-alcoholic beverages. This species, the tea shrub or CHINESE TEA (*T. Sinensis*), is 20—30 feet high, but in a state of cultivation only 5—6 feet high, with numerous branches and lanceolate leaves, which are 2—6 inches long. The flowers grow singly or two or three together in the axils of the leaves; they are rather large, white, and fragrant, with 5-parted calyx, 6—9 petals, and many stamens. By cultivation for many centuries, numerous varieties of this plant have been produced in China, some of which have been reckoned as distinct species, particularly *T. viridis*, formerly supposed to yield green tea, *T. Bohea*, formerly supposed to yield black tea, and *T. stricta*. Of these, the first-named has the longest, and the last has the shortest leaves The Assam Tea, which has been called *T. Assamensis*, appears also to be a mere variety of the same species.

Tea Plant (*Thea Sinensis*)

The cultivation of tea in China is chiefly confined to the regions between N. lat. 24°—35° and E. long. 115°—122°. Tea for domestic use is, however, cultivated both in more southern and more northern regions. The plant is to be accounted subtropical, but bears a tropical climate well, and can also accommodate itself to cold winters. In the neighbourhood of London it often endures all the frost of winter without protection. In few of the countries into which it has been introduced, however, is the flavour of the dried leaf such as it is in China. The use of tea is said to have been introduced into China itself from the Corea about

the 4th c. of the Christian era, and to have extended to Japan about the 9th century. The Chinese cultivate it chiefly on the southern slopes of hills, in poor but well-watered soil, to which no manure is applied. A new plantation is made by sowing the seed in holes at proper distances, two or three seeds being put into a hole to secure a plant. The first crop is obtained in the third year, when the shrub is by no means full-grown. When about seven years old, it yields only a scanty crop of hard leaves, and is cut down, when new shoots rise from the root, and bear fine leaves in abundance. This is repeated from time to time, till the plant dies, at about the age of thirty years.

History and Commerce.—All that can be affirmed regarding the early history of this beverage is, that it appears to have been used for ages in China, where it is believed by the natives to be indigenous. It first became known to Europeans at the end of the 16th c., though it is only mentioned by the Portuguese writer Maffei in his *Historiæ Indicæ*, who refers to it as a product both of China and Japan. The first reference to it by a native of Britain is in a letter dated 27th June 1615, written by a Mr. Wickham, which is in the records of the East India Company; and it is curious to observe that both the Portuguese and English writers referred to use their own rendering of the native name, which is *tcha*. Maffei calls it *chia*, and Mr Wickham, *chaw*. From this time, it became gradually known to the wealthy inhabitants of London, in the form of occasional presents of small quantities from India, obtained from China, or by small lots in the markets from time to time, but always exorbitantly dear, fetching sometimes as much as £10 the lb., and never less than £5. A rather large consignment was, however, received in 1657; this fell into the hands of a thriving London merchant, Mr Thomas Garway, who established a house for selling the prepared beverage; and that house, under the name of 'Garraway's Coffee-house,' is still a famous establishment in that city. From 1660 until 1689, a duty was levied on the drink made with tea at the rate of 8*d.* per gallon; but from the latter date a duty of 5*s.* per lb., with an addition of 5 per cent. *ad valorem*, was levied. For many years, the duties, although occasionally changed, were always very high. The expiration in 1833 of the charter of the East India Company, which had held a complete monopoly of the tea-trade, produced a change; the *ad valorem* duty was abolished, and differential duties of 1*s.* 6*d.*, 2*s.* 2*d.*, and 3*s.* per lb. were substituted in 1836 for one uniform rate of 2*s.* 1*d.* per lb., to which, in 1840, was added an additional 5 per cent.; at present the duty is only 6*d.* per lb. The import of the year ending 31st March 1866 was upwards of 33,000,000 pounds-weight; amounting in value to nearly £7,000,000 sterling. In 1869 Great Britain imported 139,223,298 lbs., valued at £10,311,465, of which 111,795,639 lbs. were for home consumption. The consumption of the United States in 1870 was 40,812,188 lbs., valued at $12,386,973.

Much mystery and error for a long time existed upon the subject of the species producing the tea of commerce. By many it was said that the qualities known as black teas were produced by the species known to botanists as *Thea Bohea*, and the green teas from *T. viridis*. Others held that only one species was used to make both the black and green varieties, and that the difference arose from the method and time of preparation. The eminent botanical traveller, Mr Robert Fortune, has, however, entirely set the question at rest by investigating the matter on the spot. He found that in the Canton district, where black teas alone are prepared, only the *T. Bohea* is grown; whilst in the province of Che-kiang only *T. viridis* is grown, and green teas made. But the cultivation of the latter plant he also found to be absolutely universal in the Fokien district, although the inhabitants make only black teas. The tea-farms are mostly in the north of China, and are usually of small size, and require much attention; for the plant will only thrive in well-manured or very rich soil, and the spaces between the plants, which are four feet apart, must be kept in good order, and free from weeds. The farms always occupy the hill-sides, where the soil is deep and well drained. Although an evergreen, the leaves can only be gathered at certain seasons: the first is in April, when the new leaves begin to burst from the buds; and some of these in their most tender state are gathered and made into young hyson of the finest quality; so fine, indeed, that it has rarely been brought to England, because it is said to lose flavour by the sea-voyage. Much is, however, sent overland to Russia, where it fetches an exorbitant price. The ordinary picking begins just after the summer rains are over, at the beginning of May; and later in the season, a third picking takes place, the produce of which is inferior, and used only by the poorer classes of the country. The later gatherings are more bitter and woody than the earlier, and yield less soluble matter to water. The leaves, when freshly plucked, possess nothing of the odour or flavour of the dried leaves, these properties being developed by the roasting which the leaves undergo in the process of drying. Moreover, different qualities of tea are prepared from the same leaves, which may be made to yield green or black teas at will.

For a description of the specific processes for obtaining the green and the black teas generally, we refer to Mr Fortune's work (*Tea Countries of China*), or to Johnston's *Chemistry of Common Life*, vol. i. p. 161, in which it is quoted. It is sufficient here to remark, *first*, that, in the process of drying, the leaves are roasted and scorched in such a way as necessarily to induce many chemical changes in them; the result of such changes being to produce the varieties of flavour, odour, and taste by which the different kinds of teas are distinguished; and *secondly*, that the different colours of green and black teas are due to the mode in which the leaves are treated. For *green teas*, the leaves are roasted in pans almost immediately after they are gathered. After about five minutes' roasting, during which they make a cracking noise, become moist and flaccid, and give out a good deal of vapour, they are placed on the rolling-table, and rolled with the hands. They are then returned to the pans, and kept in motion by the hands: in about an hour, or rather more, they are well dried, and their colour, which is a dull green, but becomes brighter afterwards, has become *fixed*. The essential part of the whole operation is now over, nothing more being required than to sift and re-fire it. For *black teas*, the leaves are allowed to be spread out in the air for some time after they are gathered; they are then further tossed about till they become flaccid; they are next roasted for a few minutes, and rolled, after which they are exposed to the air for a few hours in a soft and moist state; and lastly, they are dried slowly over charcoal fires, till the black colour is fairly brought out. Hence the dark colour and distinguishing flavour of black teas seem due to the long exposure to the atmosphere in the process of drying, and the oxygen of the air acting rapidly upon the juices of the leaf, and especially upon the astringent principle during this exposure. For the purpose of giving special scents to different varieties of tea, numerous odoriferous plants are employed in different parts of

China; the cowslip-coloured blossoms of the sweet-scented olive (*Olea fragrans*) communicate an especially fragrant scent to tea.

The adulteration of tea, when the duty was very high, was probably carried on to a great extent; but notwithstanding the terrible tales of alarmists, it may be confidently asserted that no adulteration of tea is now carried on in Great Britain. In China, spurious teas have been prepared and sent to this country under the name of 'Lie teas,' but they had no sale, and of course were discontinued. The Chinese give an artificial colouring to the green teas sent to Europe because it pleases the eye, but the colouring matter is very innocuous, and is never produced by heating over copper plates—a popular error, which has been persisted in for a long time without a shadow of truth for its foundation. Prussian blue in very minute proportion, and a species of native indigo and gypsum, are the real materials employed for giving the face, as it is called.

In 1836, the culture of tea was attempted on a large scale in India, under the direction of the able and indefatigable botanists, Dr Royle and Dr Falconer; and after some difficulty, a good supply of plants was introduced to the districts of Kumaon and Gurhwal, and in the meantime plantations formed at an earlier period in Assam were making great progress: from these sources, a small but steadily increasing supply is received, and the quality is superior to a large portion of the ordinary Chinese teas; indeed, there is every reason to hope that ere long India will chiefly supply our wants in tea. Tea of excellent quality is produced in the high lands of Brazil. It has also been successfully grown in Tennessee. California will probably become a tea-producing country; 27,000 plants were introduced in 1870.

The varieties of tea are very numerous; the following are those found in the shops of Great Britain:

GREEN TEAS.—*Chinese:* (1) Gunpowder sorts—viz., Shanghae, Ping-suey or Pin's-head, Moyune, Imperial Moyune, and Canton; (2) Hyson sorts—viz., Shanghae, Shanghae young, Moyune, Moyune young, Canton young, and Twankay or Imperial Hyson. *Japanese:* Gunpowder and Young Hyson. *Java:* Gunpowder.

BLACK TEAS.—*Chinese:* (1) Congo sorts—viz. Canton, Foo-chow-foo, Hung-muey, Oopack, Kaison, and Oonam; (2) Pekoe sorts—viz., Plain Orange, Foo-chow, Scented Orange, Canton Scented Orange, and Flowery Pekoe, Oolong, and Souchong. *Assam:* Congo, Orange Pekoe, and Souchong. *Java:* Congo and Imperial. The latter is made up into little balls about the size of a pea, and is rather rare.

The use of the infusion of the leaves of tea as a beverage is general in the south-eastern parts of Asia, and has become prevalent also amongst the British—at home, and in all their colonies—the Americans, and the Dutch. In Scandinavia, tea is also much used by all who can afford it. In other parts of Europe, the use of tea is much less general, and is chiefly confined to maritime districts, towns, and the wealthy. The importation of tea overland through Russia is inconsiderable, and the sea trade is chiefly to Britain and North America.

The *substitutes* for tea, in countries where it is difficult to obtain it, are of two sorts: those which contain theine, and which consequently have the same stimulating effect; and those which are destitute of that principle, and only resemble the true tea in flavour or smell, or which possess some other stimulating principle. Of the former class are—(1) Maté (q. v.): (2) Guarana (q. v.); so rich is this material in theine that it has lately been used in Great Britain for obtaining that principle; and it has been introduced into Austria and France as a powerful medicine: (3) Coffee-leaves, which are occasionally prepared as a substitute in the West Indies; they would be more generally used were it not for the disagreeable smell of the infusion; (4) the Kola-nut, the active principle of which has quite recently been ascertained to be theine.*

The second class, or those which do not possess that principle, are very numerous; but only a few can be said to be of any importance from being in general use in the countries producing them. These are the Siberian tea—leaves of *Saxifraga crassifolia;* the Appalachian tea—leaves of *Prinos glabra;* the Labrador tea—leaves of *Ledum buxifolium;* the Chilian tea—leaves of *Eugenia ugni;* Trinidad pimento tea—leaves of *Eugenia pimenta;* and the leaves of the Partridge-berry, which are used in some parts of North America. The Faham tea of Mauritius, and a great many more, should be regarded in the light of medicines, rather than as ordinary beverages; although they are generally classed with the substitutes for ordinary tea.

Tea, in its Chemical, Physiological, and Medicinal Relations.—On submitting the ordinary com-

* Dr Daniell's observations on the kola-nut (published since the article COLA-NUT appeared) are of such importance as to demand a notice here. From time immemorial, the seeds of the kola-nut have been held in inestimable value as a luxury by the inhabitants of the vast tract between the west coast and the region of Central Africa known as Sudan; and the trade in these nuts has extended to various markets on the Mediterranean. The Portuguese, Dutch, and subsequently the English voyagers, fell into the negro predilections for this fruit; and eventually the due gratification of this want became a matter of imperative necessity. Dr Daniell's knowledge of the tonic and astringent properties of these nuts was gained during his residence on the Gold Coast, where the white inhabitants were in the habit of taking a decoction of the fresh nuts, with apparent benefit, in a particular form of endemic diarrhœa, arising more from local relaxation of the mucous membranes than from constitutional debility. On taking the medicine late, two evenings in succession, when he was afterwards suffering from an attack of this kind in Jamaica, he found that he was deprived of sleep during the remainder of the night. On intermitting the decoction, the natural rest returned. and on returning to it, the insomnia again occurred. Hence, he was led to suspect that a substance analogous to theine must be present; and a chemical analysis of the nuts yielded crystals in all respects resembling those of theine, and subsequently proved by the more careful investigations of Dr Atfield to be composed of that alkaloid. Wherever the slave-trade prevailed, the tree yielding the kola-nut (*Cola acuminata* of Robert Brown) followed as a matter of necessity, being imported and cultivated for the benefit of the negro. It was thus introduced into the Mauritius, Jamaica and other West India Islands, Brazil, Mexico, &c. It was specially intended to act in warding off the predisposition to epidemic outbreaks of suicidal mania which not unfrequently almost depopulated considerable districts. While Dr Daniell's experiments disprove the statement (contained in the article COLA-NUT) that these seeds render bad water palatable, his investigations, confirmed as they are by Dr Atfield's chemical analysis, shew, that whatever may be their food-value (which Dr Daniell estimates higher, from his observations, than Dr Atfield from their analysis), they may be advantageously substituted for coffee. See the papers by Dr Daniell, 'On the Kola-nut of Tropical West Africa,' and by Dr Atfield, 'On the Food-value of the Kola-nut,' in the *Pharmaceutical Journal* for March 1865.

mercial tea * to analysis, we find that it contains (1) a volatile or essential oil; (2) theine or caffeine, described in this work under the latter name; (3) a nitrogenous compound analogous to caseine or gluten; (4) a modification of tannin; besides gum, sugar, starch, fat, woody fibre, salts, &c. *The volatile oil* gives to tea its peculiar aroma and flavour. The proportion in which it exists is, according to Miller, about 0·79 per cent. in green, and 0·6 per cent. in black tea. It may be obtained by distilling the tea with water, and is found to exert a most powerfully stimulating and intoxicating effect. In China, tea is seldom used till it is a year old, on account of the well-known intoxicating effects of new tea, due probably to the larger proportion of essential oil which it usually contains. The headache and giddiness of which tea-tasters complain, and the attacks of paralysis to which, after a few years, persons employed in packing tea are found to be liable, are due to the action of this oil, which, according to Johnston, 'does not exist in the natural leaf, but is produced during the process of drying and roasting.'—*Chemistry of Common Life*, 1855, vol. i. p. 170.

The theine or *caffeine*, an alkaloid of weak basic properties, varies considerably in different kinds of tea. Peligot found it to range from 2·2 to 4·1 per cent. in ordinary green teas, while very rarely it amounted to 6 per cent.; whereas from the researches of Stenhouse it appears that not more than 2 per cent. is usually contained in the ordinary teas in the English market. It may readily be obtained by the following simple experiment. When dry finely-powdered tea-leaves, or a dried watery extract of the leaves, are put on a watch-glass covered with a paper cone, and the whole is placed upon a hot plate, or exposed to the heat of a spirit-lamp, a white vapour gradually rises and condenses on the interior of the cone, in the form of small crystals, which consist of theine. As it has no odour, and only a slightly bitter taste, it obviously has little to do with the taste or flavour of the tea from which it is extracted; it is, however, to the presence of this ingredient that the peculiar physiological action of tea on the animal economy is due. This substance is represented by the formula $C_8H_{10}N_4O_2$, and is remarkable for the large quantity of nitrogen (28·83 per cent.) which it contains; and which is nearly double the amount contained in albumen, fibrine, &c. It is also remarkable as occurring in plants very unlike each other, and growing in remote countries, which have by instinct been selected by different nations for the purpose of yielding a slightly exciting and very refreshing beverage (see above). From numerous experiments, it appears that the introduction into the stomach of a small quantity of theine (such as three or four grains, which is the quantity contained in about one-third of an ounce of good tea) has the remarkable effect of diminishing the daily waste or disintegration of the bodily tissues, which may be measured by the amount of solid constituents contained in the urinary secretion. And if the waste be lessened, the necessity for food to repair that waste will obviously be diminished in an equal proportion. 'In other words,' says Professor Johnston, 'by the consumption of a certain quantity of tea, the health and strength of the body will be maintained in an equal degree upon a smaller supply of ordinary food. Tea therefore saves food—stands to a certain extent in the place of food—while at the same time it soothes the body, and enlivens the mind.'—*Op. cit.*, p. 173. It should, however, be stated, that the generally accepted view, that theine checks the destruction of the tissues, has been recently called in question by an excellent experimental observer, Dr Edward Smith, in various Memoirs published in the *Philosophical Transactions* and elsewhere. If double the above quantity of theine (or of the tea containing it) be taken, there is a general excitement of the circulation, the heart beating more strongly, and the pulse becoming more rapid; tremblings also come on, and there is a constant desire to relieve the bladder. At the same time, the imagination is excited, the mind begins to wander, visions appear, and a peculiar kind of intoxication comes on; the symptoms finally terminating, after a prolonged vigil, in a sleep arising from exhaustion. It is not definitely known what changes theine undergoes in the animal economy, but when oxidised artificially, it becomes decomposed into methylamine or methylia ($CH_3.H_2.N$), hydrocyanic acid (CNH), and amalic acid ($C_4(CH_3)^4N_4O_7 + H_2O$). The *nitrogenous compound* allied to caseine or gluten constitutes about 15 per cent. of the weight of the leaf. As hot water extracts very little of this substance, a large quantity of this nutritious matter, which forms about 28 per cent. of the dried spent leaves, is thrown away. Much of it might be dissolved if a little carbonate of soda were added to the boiling water with which the tea is made; and in the brick-tea (the refuse and decayed leaves and twigs, pressed into moulds) used by the Tartars, most of this substance is utilised. They reduce the tea to powder, and boil it with the alkaline water of the steppes, to which salt and fat have been added, and of this decoction they drink from 20 to 40 cups a day, mixing it first with milk, butter, and a little roasted meal. But without the meal, mixed only with a little milk, they can subsist for weeks on this thin fluid food. To the *astringent principle*, or *tannin*, which forms from 13 to 18 per cent. of the dried leaf, tea owes its astringent taste, its constipating effect upon the bowels, and its property of communicating an ink-like colour to water containing salts of iron. Whether this ingredient contributes in any degree to the exhilarating, satisfying, or narcotic action of tea, is not known. Professor Johnston thinks it probable that it does exert an exhilarating effect, from the fact, that a species of tannin is the principal ingredient of the Indian betel-nut, which, when chewed, produces a mild and agreeable form of intoxication.

It is usual to judge of the quality of a tea by its aroma, and by the flavour and colour of the infusion which it yields; but to these tests should be added the determination of the amount of soluble matter which it readily yields to boiling water. It is stated by Miller that our ordinary tea contains about 45 per cent. of soluble matter; but the independent researches of Davy and Peligot shew that boiling water seldom extracts more than one-third of the weight of the dry tea; while in J. Lehmann's experiments, only one-sixth (15·5 per cent.) was extracted. Good tea should, moreover, not yield more than 5

* The following comparative analyses of tea, coffee, and the dry kola-nut are interesting, as shewing how nearly they contain the same organic constituents, although in different proportions:

	100 Parts of Tea contain	100 Parts of Coffee contain	100 Parts of Kola-nuts contain
Water,	5	12	13·65
Theine,	3	1·75	2·13
Caseine,	15	13	6·33
Gum,	18	9	10·67
Sugar,	3	6·5	
Starch,	a trace	a trace	42·00
Tannin,	26·25	4	...

Fat,	4	12	
Fibre,	20	35	20·00
Mineral substances	5	6·7	3·20

or 6 per cent. of ash when incinerated; and a portion of this is probably due to the colouring matter which the Chinese add to the green teas prepared for the foreign market. For this purpose, they used to employ a mixture of Prussian blue and gypsum, but indigo is now commonly used, which is probably harmless. Drinkers of green tea who wish to know which of these adulterations they are swallowing, may easily determine the point by the following simple experiment. 'If a portion of the tea be shaken with cold water, and thrown upon a bit of thin muslin, the fine colouring matter will pass through the muslin, and settle to the bottom of the water. When the water is poured off, the blue matter may be treated with chlorine, or a solution of chloride of lime. If it is bleached, it is indigo; if potash makes it brown, and afterwards a few drops of sulphuric acid make it blue again, it is Prussian blue.'—Johnston, *op. cit.*, p. 181, *note*.

Much has been written regarding the dietetic and medical uses of tea. While some physicians have over-praised its value, others have regarded it as the source of numerous diseases, especially of the nervous system. In his admirable work on *Hygiene*, Dr Parkes remarks that 'tea seems to have a decidedly stimulative and restorative action on the nervous system, which is perhaps aided by the warmth of the infusion. No depression follows this. The pulse is a little quickened. The amount of pulmonary carbonic acid is, according to Dr E. Smith, increased. The action of the skin is increased; that of the bowels lessened. The kidney excretion is little affected; perhaps the urea is a little lessened, but this is uncertain, the evidence with regard to the urine being very contradictory.' Dr E. Smith considers that 'tea promotes all vital actions.' Dr Parkes regards it as a most useful article of diet for soldiers, and it is well known that cold tea is now frequently preferred to beer or cider by reapers and other labourers engaged in laborious work in hot weather. As a general rule, tea is very prejudicial to young children, and is not a suitable drink till growth is completed; and adults of an irritable constitution, or a leucophlegmatic temperament, often suffer from its use. Those with whom tea does not agree, will generally find cocoa the best substitute. Old and infirm persons usually derive more benefit and personal comfort from tea than from any other corresponding beverage. In fevers, tea, in the form of a cold weak infusion, is often of great service. In persons of a gouty and rheumatic tendency, and especially in such as are of the *Lithic Acid Diathesis* (q. v.), weak tea, taken without sugar, and with very little milk, is the best form of ordinary drink. In some forms of diseased heart, tea proves a useful sedative, while in other cases it is positively injurious; and a cup of strong green tea, especially if taken without sugar or milk, will often remove a severe nervous headache. It is nearly as powerful an antidote in cases of opium-poisoning as coffee; and very strong tea has been the means of preserving life, in cases of poisoning by tartar emetic, the tannin being in these cases the active agent. It is impossible to speak too strongly against the habit occasionally adopted by students of keeping off their natural sleep by the frequent use of strong tea. The persistent adoption of such a habit is certain to lead to the utter destruction of both bodily and mental vigour.

TEAK, the name of two kinds of timber, valuable for ship-building and other purposes, one of which is known as INDIAN T., and the other as AFRICAN TEAK. The trees which produce them belong to very different orders. INDIAN T. (*Tectona grandis*) is a tree of the natural order *Verbenaceæ*. It is found in the mountainous parts of Malabar, and elsewhere in Hindustan, and in the Eastern Peninsula, Ceylon, Java, &c. It has been introduced in some parts of India, in which it is not indigenous. Dr Roxburgh introduced it in the low grounds of the Circars as early as 1790. It has been planted in some parts of Ceylon, but not yet with much result, as it takes 60 or 80 years to grow to a large size. It is a beautiful tree, attaining a height sometimes even of 200 feet, and rising above all the other trees of the East Indian forests. It has deciduous oval leaves of 12—24 inches long, covered with rough points; great panicles of white flowers, with 5—6-cleft corolla, and 4-celled drupes about the size of a hazel-nut. Its flowers are used medicinally in cases of retention of urine, and its leaves by the Malays in cholera. Silk and cotton stuffs are dyed purple by the leaves. The timber is the most valuable produced in the East Indies; it is light and easily worked, strong, durable, and not liable to the attacks of insects. It abounds in silex, and resembles coarse mahogany. It is extensively used for ship-building, for which purpose it is imported into Britain. All the finest ships built in India, and many built in England, are of teak. The most extensive T. forests are in Pegu. The T. generally rather grows in clumps in forests than forms forests of itself.—AFRICAN T., sometimes called AFRICAN OAK, is a timber similar to East Indian teak. It is now believed to be the produce of *Oldfieldia Africana*, a tree of the natural order *Euphorbiaceæ;* but the leaves of many different trees have been brought to botanists as those of the African teak.

Indian Teak (*Tectona grandis*).

TEAL (*Querquedula*), a genus of ducks (*Anatidæ*) with very slightly lobed hind-toe, narrow bill, as long as the head, the sides nearly parallel, or widening a little at the end, the wings pointed, the tail moderately large, and wedge-shaped. Some naturalists divide the genus into two—*Nettion*, in which the bill has parallel sides, and a small nail at the tip; and *Querquedula*, in which it is widened, and has a larger nail. The species are numerous, the smallest of the ducks, and widely distributed over the world. They generally frequent rivers and lakes, feeding principally at night on aquatic insects, worms, molluscs, seeds, &c. The COMMON T. (*Q. or N. crecca*) is plentiful in Britain and in most parts of Europe. It is occasionally but rarely seen in North America. Its whole length is about 14 inches. It is a very beautiful bird; the head of the male brownish red, the body transversely undulated with dusky lines, a white line above, and another beneath the eye, the speculum black and green. It makes its nest on the margins of lakes or rivers, of decayed vegetable matter lined with down, and lays eight or ten eggs. Its flesh is extremely delicate. It was domesticated by the ancient

Romans, and seems capable of being advantageously introduced into our poultry-yards.—The GARGANEY (q. v.) is another British species.—The GREEN-WINGED T. (*Q.* or *N. Carolinensis*) of North America is very similar to the Common T., but it is

Common Teal (*Querquedula crecca*), male and female.

at once distinguished by a white crescent in front of the bend of the wings. It is occasionally seen in Europe. In its summer migrations, it visits very northern regions.—The BLUE-WINGED T. (*Q. discors*) is very abundant in many parts of North America. It is rather larger than the Common Teal. It is easily domesticated.

TEAR-PITS. See DEER.

TEA′SEL (*Dipsacus*), a genus of plants of the natural order *Dipsaceæ* or *Dipsacaceæ.* This order consists of herbaceous and half-shrubby exogenous plants, with opposite or whorled leaves, and flowers in heads or whorls, surrounded by a many-leaved involucre. About 150 species are known, natives of the temperate parts of the Old World. In the

Fuller's Teasel (*Dipsacus fullonum*).

genus *Dipsacus*, the flowers are separated from each other by long, stiff, prickle-pointed bracts. The only valuable species of the order is the FULLER'S T., or CLOTHIER'S T. (*D. fullonum*), a native of the south of Europe, naturalised in some parts of America. It is a biennial, several feet high with sessile serrated leaves, the stem and leaves prickly; and with cylindrical heads of pale or white flowers, between which are oblong, acuminated, rigid bracts, hooked at the point. The heads are cut off when the plant is in flower, and are used in woollen factories, and by fullers and stocking-makers, for raising the nap on cloth. No mechanical contrivance has yet been found to equal T. for this purpose; to which the hooked points, the rigidity, and the elasticity of the bracts are admirably adapted. The heads of T. are fixed on the circumference of a wheel or cylinder, which is made to revolve against the surface of the cloth. T. is cultivated in many parts of Europe, and is imported into Britain from Holland and France. It is cultivated to some extent in England, particularly in Somersetshire and Yorkshire. The seed is sown in March, on well-prepared strong rich land, and the plants thinned out to a foot apart. In August of the second year, the heads are ready to be cut. They are packed in bundles of 25 each, and about 160 such bundles are the usual produce of an acre. The flowers of T. abound in honey, and the seeds are used for feeding poultry.

TECHNICAL EDUCATION. See SUPP. in Vol. X.

TECHNO′LOGY (Gr. *techne*, art) is the name given to the science or systematic knowledge of the industrial arts. In its widest sense, it would embrace the whole field of industry, but it is restricted in usage to the more important manufactures (spinning, weaving, metallurgy, brewing, &c.). Technology is not an independent science, having a set of doctrines of its own, but consists of applications of the principles established in the various physical sciences (chemistry, mechanics, mineralogy, &c.) to manufacturing processes. A complete course of instruction in technology could only be of the most superficial kind. The essential preparation for any branch of the manufacturing arts is the study of the fundamental physical sciences which are taught in schools and universities; and the special applications to the branch which the student has to pursue professionally can best be learned from special treatises on the subject in connection with practice in a manufacturing establishment. A general knowledge, however, of the arts of manufacture is interesting and instructive to all, and hence the museums of industry recently established by the British government, and yet in their infancy, promise to be of great benefit to the public in general, as well as to the professional manufacturer.

TECTIBRANCHIA′TA, an order of gasteropodous molluscs, having the gills arranged only on one side, resembling pinnatifid leaves, and covered by the mantle and a small shell. The T. feed mostly on sea-weeds, but some of them also eat animal substances. To this order belongs the SEA-HARE of the Mediterranean (*Aplysia depilans*), which is sometimes a foot in length, and was in former times an object of superstitious dread, on account of its grotesque form, and of a violet-coloured fluid which it ejects from the inner surface of the mantle when molested, and which was supposed to be poisonous.

TE DEUM (*Te Deum laudamus, Te Dominum confitemur*), a well-known hymn (so called from its first words) of the Roman Catholic Church, sung on all occasions of triumph and thanksgiving, and a theme upon which the most celebrated composers have from time immemorial exercised their musical genius. The hymn is one of the most simple, and at the same time the most solemn and majestic in the whole range of the hymnology of the Roman Catholic Church. Its authorship is uncertain. An ancient chronicle (long posterior, however, to the supposed date of the composition of this hymn, and

otherwise destitute of authority) describes the Te Deum as the joint production of Sts Ambrose and Augustine, into which they both burst forth by a common inspiration on occasion of the baptism of Augustine. From this supposed origin, the Te Deum is commonly called the Ambrosian Hymn. It is ascribed by other authorities to Hilary of Poitiers, but is most probably considerably later. Besides its general use on occasions of joyous celebrations, the Te Deum forms part of the daily 'Matins' of the Roman Breviary, and is recited at the end of 'Matins' on all festivals, and on all Sundays except those of Advent and Lent, to which, as being seasons of penance, the Te Deum is considered inappropriate. Its use is very ancient. It is universally admired by Protestants as well as Roman Catholics, and exhibits none of the peculiarities of Roman Catholic theology.

TEEL-SEED. See OILS and RAM-TIL.

TEES, a river in the north of England, is 90 miles long, flows east, forming the boundary between the counties of Durham (q. v.) and York (q. v.), and falls into the North Sea, ten miles below Stockton, to which town it is navigable for vessels of 60 tons burden.

TEETH, THE. A tooth is described by Professor Owen, the highest authority on this subject, as 'a hard body attached to the mouth or commencement of the alimentary canal, partially exposed when developed. Calcified teeth are peculiar to the vertebrates, and may be defined as bodies primarily, if not permanently, distinct from the skeleton, consisting of a cellular and tubular basis of animal matter containing earthy particles, a fluid, and a vascular pulp.'—*The Anatomy of Vertebrates*, 1866, vol. i. p. 359. 'They present,' says the same writer, 'many varieties as to number, size, form, structure, position, and mode of attachment, but are principally adapted for seizing, tearing, dividing, pounding, or grinding the food.* In some species, they are modified to serve as formidable weapons of offence and defence; in others, as aids in locomotion, means of anchorage, instruments for uprooting or cutting down trees, or for transport and working of building materials. They are characteristic of age and sex; and in man they have secondary relations, subservient to beauty and to speech. Teeth are always intimately related to the food and habits of the animal, and are therefore highly interesting to the physiologist; they form, for the same reason, important guides to the naturalist in the classification of animals.'—*Circle of the Sciences; Organic Nature*, vol. i. p. 264.

True teeth consist of one, two, or more tissues, differing in their chemical composition and in their microscopical appearances. 'Dentine,' which forms the body of the tooth, and 'cement,' which forms its outer crust, are always present; the third tissue, the 'enamel,' when present, being situated between the dentine and cement. The *dentine*, which is divided by Professor Owen into hard or true dentine, vaso-dentine, and osteo-dentine, consists, according to that physiologist, of an organised animal basis, disposed in the form of extremely minute tubes and cells, and of earthy particles; these earthy or calcareous particles being either blended with the animal matter of the interspaces and walls of the tubes and cells, or contained in a minutely divided state in their cavities. The tubes and cells contain, besides the calcareous particles, a colourless fluid, which is probably transuded blood plasma, or *liquor sanguinis*, and contributes to the nutrition of the dentine. In hard or true dentine, the *dentinal tubes* proceed from the hollow of the tooth known as the *pulp cavity*, in a slightly wavy course, nearly at right angles to the outer surface (see fig. 1). 'The hard substance of the tooth is thus arranged in hollow columns, perpendicular to the plane of pressure, and a certain elasticity results from these curves; they are upright where the grinding surface of the crown receives the appulse of the opposing tooth, and are horizontal where they have to resist the pressure of contiguous teeth. The tubuli, besides fulfilling the mechanical ends above stated, receive the plasma transuded from the remains of the vascular pulp, which circulates by anastomosing branches of the tubuli through the dentine, maintaining a sufficient, though languid vitality of the system. The delicate nerve-branches on the pulp's surface, some minute production of which may penetrate the tubuli, convey sensations of impressions affecting the dentine—sensations of which every one has experienced the acuteness, when decay has affected the dentine, or when mechanical or chemical stimuli have "set the tooth on edge;" but true dentine has no canals large enough to admit capillary vessels with the red particles of blood.' When a part of the primitive vascular pulp from which the dentine is developed, remains permanently uncalcified, red blood is carried by 'vascular canals' into the substance of the tissue. Such dentine is called *vaso-dentine*, and is often combined with true dentine in the same tooth, as, for example, in the large incisors of certain rodents, the tusks of the elephant, and the molars of the extinct megatherium. Another modification of the dentine is when the cellular basis is arranged in concentric layers around the vascular canals, and contains 'radiated cells,' like those of bone: this is termed *osteo-dentine*, and resembles true bone very closely. The *cement* always corresponds in texture with the osseous tissue of the same animal, and wherever it occurs in sufficient thickness, as on the teeth of the horse or ox, it is traversed like bone by vascular canals. Moreover, when the osseous tissue contains minute radiated cells, precisely similar cells are likewise present in the canal, and constitute its most marked characteristic. The relative densities of dentine and cement vary according to the amount of earthy matter. In the complex grinders of the elephant and some other animals, the cement, which forms nearly half the mass of the tooth, wears down sooner than the dentine. The *enamel* is the hardest of all the animal tissues, and contains no less than 96·4 per cent. of earthy matter (mainly phosphate of lime), while dentine contains only 72 per cent., and cement and ordinary bone only 69 per cent. of earthy matter. The earthy matter is contained in

v, vaso-dentine; *d*, dentine; *c*, cement.

to their most complicated forms, we find a very few examples (solely among fishes—as, for example, the wrasse), in which teeth consist of a single tissue—a very hard kind of non-vascular dentine. Teeth consisting of dentine and vaso-dentine are very common in fishes, the hard dentine being external, and performing the office of enamel. Dentine and cement, the latter forming a thick outer layer, constitute the grinding teeth of the dugong. In the teeth of the sloth, the hard dentine is reduced to a thin layer, and the chief bulk of the tooth consists of vaso-dentine internally, and a thick crust of cement externally. 'The human teeth and those of the carnivorous mammals appear at first sight to be composed of dentine and enamel only; but their crowns are originally, and their fangs are always covered by a thin coat of cement. There is also commonly a small central tract of osteo-dentine in old teeth. The teeth called compound or complex in *Mammalia* differ as regards their composition from the preceding only by the different proportion and disposition of the constituent tissues. Fig. 3 is a longitudinal section of the incisor of a horse; *d* is the dentine, *e*, the enamel, and *c*, the cement, a layer of which is reflected into the deep central depression of the crown; *s* indicates the coloured mass of tartar and particles of food which fills up the cavity, forming the "mark" of the horse-dealer.'—*Organic Nature*, vol. i. p. 267. Far more complex forms of teeth than this may be produced by peculiar arrangements, chiefly inflections, of the tissues. Certain fishes, and a family of gigantic extinct batrachians, to which Owen has, from this remarkable peculiarity, given the name *Labyrinthodons* (q. v.), exhibit this kind of complexity in a remarkable degree. Another kind of complication is produced by an aggregation of many simple teeth into a single mass. These compound teeth are most

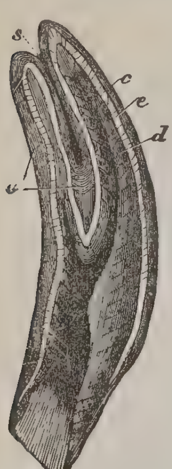

Fig. 3.—Longitudinal Section of the Incisor of a Horse.

common in fishes, but are occasionally met with in mammals. The teeth of the Cape ant-eater (*Orycteropus*), depicted and described by Owen in *The Circle of the Sciences*, are of this kind, each tooth being composed of a congeries of long and slender prismatic denticles of dentine, which are cemented together. In the elephant, the compound molars belong to this class, the denticles being in the form of plates vertical to the grinding surface, and transverse to the long diameter of the tooth. When the tooth is bisected vertically and longitudinally, the three substances, dentine, *d*, cement, *c*, and enamel, *e*, are seen blended together (see fig. 4).

Our limited space forbids our entering into any details regarding the teeth of *fishes*, further than to remark, that, in regard to their number, form, substance, structure, situation, or mode of attachment, they offer a greater and more striking series of varieties than do those of any other class of animals.

Fig. 4.—Longitudinal Section of part of an Elephant's Grinder.
c, the cement; *d*, the dentine; *e*, the enamel; *p*, the common pulp-cavity; *r*, one of the roots of this complex tooth.

In all fishes, the teeth are shed and renewed, not once only, as in mammals, but frequently during the whole course of their lives; and, as Professor Owen observes, 'this endless succession and decadence of the teeth, together with the vast numbers in which they often co-exist in the same fish, illustrate the law of vegetation or irrelative repetition, as it manifests itself on the first introduction of new organs in the animal kingdom.' While comparatively few fishes are entirely devoid of teeth, we find that in the class of *Reptiles*, the whole order of *Chelonia* (tortoises and turtles), the family of toads (*Bufonidæ* in the order *Batrachia*), and certain extinct genera of *Sauria* (lizards), are toothless. Frogs have teeth in the upper, but not in the lower jaw. Newts and salamanders have teeth in both jaws and upon the palate; and teeth are found on the palate as well as on the jaws of most serpents,

In most lizards, and in crocodiles, the teeth are confined to the jaws. The teeth in reptiles are for the most part simple, of a conical form, and adapted, as in the case of most fishes, for seizing and holding, but not for dividing or masticating the food. In no reptile does the base of the tooth branch into fangs; and, as a general rule, the base of the tooth is anchylosed to the bone which supports it. The completion of a tooth is soon followed by preparation for its removal and succession, the faculty of developing new tooth-germs being apparently unlimited in this class. For further details regarding the teeth of fishes and reptiles, the reader is referred to Professor Owen's invaluable *Anatomy of the Vertebrates*, 1866, vol. i. pp. 359—409. Birds having no teeth, we proceed to the consideration of the dental system of *mammals*—a class which includes a few genera and species that are devoid of teeth. The true Ant-eaters (*Myrmecophaga*), the Pangolins or Scaly Ant-eaters (*Manis*), and the Spiny Monotrematous Ant-eater (*Echidna*), are strictly toothless. The Ornithorhynchus has horny teeth, and the Whales (*Balæna* and *Balænoptera*) have transitory teeth, succeeded in the upper jaw by whalebone. The female Narwhal exhibits nothing more than the germs of two teeth in the substance of the upper jaw; in the male, one of these germs becomes developed into the remarkable weapon which specially characterises the animal, and to which its generic term, *Monodon* (single tooth), is due. In the Great Bottle-nose Whale, in the adult state, there are only two teeth (here occurring in the lower jaw); whence the name *Hyperoödon bidens*. The Elephant has never more than one entire molar, or parts of two, in use on each side of the upper and lower jaws; to which are added two tusks, which are modified incisors, more or less developed, in the upper jaw. Some rodents have 2 grinders on each side of both jaws, which, added to the 4 cutting-teeth in front, make 12 in all; but the common number of teeth in this order is 20, although Hares and Rabbits have 28 each. The number of teeth, 32, which characterises man, the apes of the old world, and the true ruminants, is the average one of the class Mammalia; but according to Professor Owen, 'the typical number is 44.' 'I have been led,' he observes, 'chiefly by the state of the dentition in most of the early forms of both carnivorous and herbivorous mammalia which flourished during the eocene tertiary periods, to regard 3 incisors, 1 canine, and 7 succeeding teeth, on each side of both jaws, as the type-formula of diphyodont * dentition.'—*On the Classification and Geographical Distribution of the Mammalia*, 1859, p. 18. A few of the Monophyodonts possess from 80 to 100 teeth. See the article MAMMALIA. The hog, the mole, the gymnure, and the opossum, are among the few existing quadrupeds which retain the typical number and kinds of teeth. The formula expressing the number of the different kinds of teeth—viz., the incisors or cutting-teeth, the canines or dog-teeth, the premolars, and the molars or true grinders, commonly known as the *dental formula*, is described in the article DENTITION, in which the *milk* or *deciduous* teeth, and the order in which they appear, are also described. It is only in the Mammals that we have a well-marked division of the teeth into the four kinds of incisors, canines, premolars, and molars, each of which claims a brief description.

The *incisors*, or cutting-teeth, are situated in front, and possess a single conical root or fang, and a vertical crown bevelled behind, so as to terminate in a sharp cutting edge. These teeth are specially fitted, as their name implies, for cutting the food. In man, there are two of these incisors in each side of each jaw. In herbivorous animals, they crop the herbage; in rodents (the rabbit, hare, rat, beaver, &c.), these teeth are very much developed, and differ from any other teeth occurring in Mammals in this respect, that their growth continues throughout life; and if their length does not constantly increase, it is because their free extremity or edge is worn down by trituration as fast as they grow at the base from their roots.

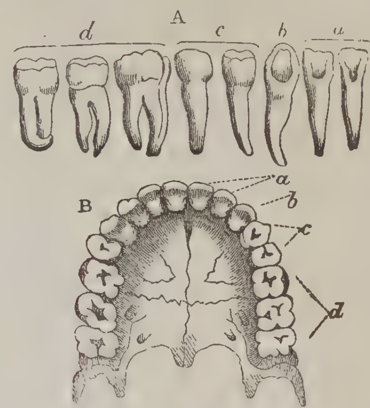

Fig. 5.

A, the separate human teeth as they occur in the half-jaw of the adult; B, the human teeth *in situ* in the upper jaw; *a*, *a*, incisors; *b*, *b*, canine; *c*, *c*, premolars; *d*, *d*, true molars.

The *canines* (so called from their prominence in the dog) come next to the incisors. Their crown is rather conical than wedge-shaped, and their fang sinks more deeply into the jaw than in the case of the incisors. In all carnivorous animals, they are largely developed, being obviously formed for tearing the flesh of their prey. In man, there is one canine tooth in each half-jaw; and there is never more than this number in any of the lower animals.

The *premolars* (known also as bicuspids and false molars) come next in order to the canines; they are smaller than the latter, and their crown presents two pyramidal eminences. In man, there are two premolars in each half-jaw. Their function more nearly approaches to that of the true molars behind them, than to that of the canines.

The *true molars* (or multicuspids) are placed most posteriorly. They are remarkable for their comparatively great size, the square form of the upper surface, on which are from three to five elevations or cusps, and for their short root, which is divided into from two to five branches, each of which is perforated at its extremity. In man, there are three molars in each half-jaw, the posterior one being termed the wisdom-tooth, from its being cut the latest: they are especially employed for grinding the food, under the action of the muscles of the lower jaw.

The teeth are so admirably adapted for the special purposes which they are called upon to fulfil, that it is generally easy, from a careful examination of them, to say to what class of animals they

* Professor Owen divides the class Mammalia, in regard to the times of formation and the succession of their teeth, into the *Monophyodonts* (Gr. *mono-*, once; *phy-*, generate; and *odont*, tooth), or those that generate a single set of teeth, as the sperm whales, dolphins, porpoises, armadillos, and sloths; and the *Diphyodonts* (derived from *di*, twice, &c.), or those that generate two sets of teeth, as the Mammals generally, with the above exceptions.

belong, and to draw various conclusions regarding the habits and structure of the class generally. Thus, in carnivorous animals, the molars are not grinding-teeth, but present sharp cutting edges, and those of the upper and lower jaw overlap each other; resembling a pair of scissors in their action. In insectivorous animals, the molars have a tuberculated surface, with conical points and depressions, so arranged as to lock into each other. In frugivorous animals, living on soft fruits, these teeth are provided with rounded tubercles, while in herbivorous animals, they have a broad, rough surface, resembling a millstone.

There is also a close connection between the articulation or joint of the lower jaw and the nature of the food used by the animal. Thus, in purely carnivorous animals, in which the teeth simply tear and cut the food, no grinding motion is required, and the jaw is capable only of a simple hinge-motion in the vertical plane; while in herbivorous animals, the joint is so constructed as to allow of extensive sliding and lateral motion of the lower molar teeth upon the upper. In man, both the form of this articulation and the general character of the teeth, point to an intermediate position in relation to food, and form a good physiological argument for the mixed diet which general custom has decided to be most favourable and natural to our species.—For further information on this subject, the reader is referred, not only to the three works of the professor from which quotations have been made in this article, but to his splendid *Odontography* (1844), and to his article 'Teeth,' in *The Cyclopædia of Anatomy and Physiology;* to F. Cuvier, *Sur les Dents*, &c.; and to De Blainville's *Osteographie.*

Diseases of the Teeth.—The dangers to which infants and children are exposed during the process of teething, are noticed in the article Dentition; and we shall therefore here confine our remarks to the affections of the permanent teeth, of which the following are the most important:

1. *Caries of the teeth* usually commences in the dentine immediately below the enamel, a yellow or brown spot being observed on the surface of the tooth over the affected part. The tissue soon becomes softened, and a small cavity is formed, which, after a time, presents an external opening, in consequence of the unsupported enamel giving way. The substance of the tooth now decays more rapidly, and the caries gradually approaches the central or pulp cavity, which at length is opened. Hitherto, there has been little or no suffering, but now pain is experienced under the action of irritant substances, heat, cold, &c. Inflammation proceeding to suppuration takes place; the pulp is gradually destroyed by ulceration; and the body of the tooth, thus deprived of its nourishment, decays, and leaves nothing but the outer coating of enamel, which then breaks away by degrees, till nothing but the fangs of the tooth remain, and these usually cease to give pain. Caries is not only a common cause of toothache, but frequently gives rise to obstinate headache, pain in the ear, deafness, squinting, impossibility of bearing the light (photophobia), and other anomalous symptoms, which immediately disappear upon the removal of the diseased tooth. In these cases, the tooth may never have ached, but will be found painful when pressed up or smartly struck. The primary cause of caries is constitutional, and it especially occurs in scrofulous and ill-nourished persons, or in those whose health is broken down by too frequent pregnancies, prolonged lactation, the abuse of mercury, &c. The direct or exciting causes are usually described as: (1) Such as destroy the integrity of the enamel, and thereby expose the dentine to the influence of irritant substances; or (2) such as operate upon the vital susceptibilities of the dental tissues. Among the former are acids and other corrosive substances taken into the mouth, sour eructations, the attrition of opposing surfaces of the teeth, and all kinds of mechanical violence; while among the latter may be mentioned hot and cold drinks, especially when taken in quick alternation. The excessive use of sugar is also commonly regarded as a cause of the disease. Many of the best dentists, however, deny that acids (when taken medicinally) or the abrasion of the enamel can give rise to caries.

With regard to treatment, it may be observed, that if the caries be slight and recent, the decayed portion must be removed, and the cavity filled up with gold, as described in the article Dentistry. 'But,' says Dr Druitt, who on dental matters always quotes the opinions of Mr Tomes, the most scientific living authority on the diseases of the teeth, 'if the decay has advanced far towards the pulp-cavity, or has laid that open, it may be necessary first to employ aperients and tonics, and use some application to deaden the sensibility of the tooth, so as to enable it to bear the stopping, and to protect it meanwhile from contact with food and saliva.' Many a useless visit to the dentist might be avoided, if the patient would take an aperient dose of Epsom salts two or three consecutive mornings; and after cleansing out the cavity with dry cotton-wool, would insert twice a day a plug of that substance, moistened in Eau de Cologne, or, still better, in either of the following solutions: (1) Mastic solution, formed by dissolving a drachm of mastic in an ounce and a half of Eau de Cologne; or (2) Ethereal tincture of tannin, formed by dissolving a drachm each of tannin and mastic in an ounce and a half of sulphuric ether. By these means, a painful tooth may be often brought into a state in which it will bear stopping. The patient's sensations will warn him against drinking very hot or cold, or sweet or acid fluids, and against exposure to cold draughts of air. Whenever the teeth exhibit a tendency to rapid decay, general tonic treatment is indicated.

2. *Necrosis* is an affection which is characterised by blackness of the tooth and looseness in its socket. It may be caused by violence, accompanied with destruction of the nutrient vessels, or by inflammation of the pulp. If the tooth gives trouble, it must be extracted. Necrosis of the teeth is quite distinct from the very destructive necrosis of the dental alveolar processes and of the jaws generally, which results from the poisonous action of phosphorus fumes, or from the very similar affection which sometimes follows the eruptive fevers. For an account of the singular and terrible disease from which artisans employed in making lucifer-matches suffer, in consequence of their inhaling the fumes of phosphorus (probably in the form of phosphorous acid), which was first noticed in 1839, we may refer to a review of Von Bibra and Geist's exhaustive treatise (in German) on the subject in the *British and Foreign Medico-chirurgical Review* for April 1848; and to an article on 'Phosphorus Workers,' in the Fifth Report of the Medical Officer of Health. Reference is also made to the disease in the article Phosphorus in this work. The necrosis and exfoliation of the alveolar processes and portions of the jaws in children, consequent upon the eruptive fevers, is accompanied by the shedding of the teeth; and according to Mr Salter, surgeon-dentist to Guy's Hospital, who was the first to describe its true nature, is essentially the same as the necrosis in phosphorus-poisoning, and, like it, is the result of the local application of a specific poison, generated within the individual, to the vascular parts of the teeth. For a description of

this remarkable disease, and of the treatment to be adopted, we must refer to Mr Salter's article on 'Exanthematous Jaw-necrosis,' in Holmes's *System of Surgery.*

3. *Alveolar abscess* may be defined as a suppuration around the fang or fangs of a tooth, usually carious, accompanied by absorption of the bony walls of the alveolar process, and enlargement of the little sac of pus or matter, which gradually makes its way to the surface, 'either along a canal by the side of the fang of the tooth opening at the edge of the gum, or through the gum itself at a point corresponding to the end of the root (or roots) of the tooth implicated. When, however, the fangs are unusually long, or the reflection of the mucous membrane from the gum to the cheek or lip is very superficial, this same discharge may burrow still more outwardly, and find its exit upon the surface of the face.'—Salter, *op. cit.*, p. 2. When the discharge bursts, as it most commonly does, through the gum, the alveolar abscess is reduced to its simplest form, and is known as a *gum-boil.* When the discharge takes place in the region of the cheek or chin, the true nature of the case may easily be mistaken by a careless surgeon, who might refer the symptoms to bone-disease. The cause of this affection is either caries or necrosis. In its earliest stage, the disease may be cut short by the extraction of the affected tooth, or even by the removal of the stopping, if the tooth is a stopped tooth. If it is desirable to save (for appearance' sake or otherwise) a threatened tooth, the gum should be freely leeched, and hot fomentations applied to the swollen part of the face, and the system should be briskly purged. As soon as matter can be detected, it should be allowed to escape by a puncture made through the gum—an operation which is followed by immediate relief, and by rapid subsidence of the swelling, although pus continues to be discharged for a considerable time. Indeed, the disease seldom ceases altogether till the offending tooth is removed. When the abscess shews symptoms of pointing on the face, the tooth must be at once extracted, and more serious surgical interference will probably be necessary.

4. *Toothache* is not so much a disease as a symptom of various morbid states of the affected part, which, for convenience, may be classed under this single heading. 'Toothache,' says Dr Wood, 'offers every possible variety in degree, character, and duration. The pain runs through all the grades which intervene between a slight sensation of uneasiness and unsupportable agony. It may be dull, aching, heavy, sharp, pungent, throbbing, grinding, or lancinating. It may be continued or paroxysmal, remittent or intermittent, and regular or irregular in its recurrence. It may come in flashes, and as suddenly disappear; or may continue a long time with little variation.'—*Practice of Medicine*, 4th ed. vol. i. p. 512. According to the various conditions which give rise to it, toothache may be divided into: (*a.*) *Inflammatory toothache,* which is almost always dependent upon caries. The inflammation may be seated in the pulp of the tooth, in the nerve-twig entering the pulp-cavity, or in the periosteum investing its roots, and reflected over the interior of the alveolar cavity. There is generally some external swelling after the pain has continued for some time, and it occasionally extends to the salivary glands. The tooth is at the same time very tender, and any force applied to it aggravates the pain, which is also increased by hot and cold liquids taken into the mouth. When, as in the great majority of these cases, the pain is associated with caries, the best treatment is as follows: 'Let the patient have a dose of calomel and colocynth; confine him to spoon-diet; let him wash out the mouth with a solution of carbonate of soda in tepid water; let the gum around the tooth, and between it and its neighbours, if tumid and tender, be deeply scarified with a fine lancet; then let the cavity be filled loosely with a little bit of cotton-wool, dipped into the solution of tannin and mastic (for which the formula has been already given); and if the toothache be curable at all, this plan, with a little patience, will be almost sure to succeed. If the pain is very violent, half a grain of powdered acetate of morphia may be taken up with the cotton imbued with the tannin, which should be warmed before it is put into the cavity. As soon as the pain is relieved, the tooth, if of use, should be stopped with gold or amalgam; or if of no use, it should be extracted. It may be added, that most of the violent, burning, empirical nostrums, such as creosote, oil of thyme, &c., although they may be of service when introduced in small quantity by a skilful hand into the carious tooth at the right time, can do nothing but mischief when employed indiscriminately, as they are by the vulgar.'—Druitt's *Surgeon's Vade-mecum*, 8th ed. p. 458. (*b.*) *Neuralgic toothache* may occur either in sound or in carious teeth. It may be recognised by its occurrence in paroxysms at more or less regular intervals, and by its being attended with little or no swelling of the external parts. It is very common in the earlier months of pregnancy, and in persons of a general neuralgic tendency, and is often excited by changes in the weather. The treatment is the same as for neuralgia generally. After the bowels have been freely opened, chalybeates and quinine must be given in large doses, and frictions with veratria or tincture of aconite (both of which are energetic poisons) may be carefully applied to the gum. (*c.*) *Rheumatic and gouty toothache* may occur in sound or in carious teeth in rheumatic or gouty persons. The constitutional treatment applicable to these diseases must be tried, together with the local applications already noticed.

5. *Falling of the teeth,* due to absorption of the socket, may be regarded as almost an ordinary consequence of old age; but it frequently occurs under the popular name of *scurvy of the gums* in middle age, although very seldom before the 30th year. True scurvy, gangrene of the mouth, or mercurial inflammation of the gums, may cause the loosening of the teeth at any age; but there are two other conditions which lead to the same result. In one of these affections, the gums swell, and assume a deep red colour, and the inflammation appears to be propagated into the alveoli, producing a thickening of the periosteum, and a consequent elevation of the tooth above its ordinary level. By frequently recurring attacks of this inflammation, the tooth is lifted out of its socket, while the gum retreats from the neck, and leaves a portion of the roots exposed. The tooth thus deprived of its support at length falls, after which the gum heals, and the patient is relieved. The remedies indicated are those tending to relieve inflammation of the gum, but they are seldom successful. In the other affection, there is conjoined suppuration of the gums and sockets, and the disease first shews itself by an oozing of pus from behind the edges of the gums when they are pressed. From the absorption of the sockets, and the simultaneous retreat of the gums, the teeth, as in the previous case, at length fall out, if they have not, for the patient's comfort, been previously extracted. Little can be done in the way of treatment in this form of the affection.

6. *Painful and difficult eruption of the wisdom-teeth* requires a few remarks. The cutting of these teeth is often accompanied by distressing symptoms which may be protracted for months, or even years

unless surgical aid is called in. The difficulties arise from the position occupied by these teeth, so close to the joint of the lower jaw, where the mucous membrane is reflected from the gums to the cheek and fauces, combined with the very common condition, that the jaw is not sufficiently elongated backwards to allow the *dentes sapientiæ* to range in the horizontal series with the other teeth.' This mechanical difficulty not only holds back these teeth in their bony bed, but it often prevents their proper direction of growth. As a consequence of these displacements in the upper jaw, it often happens that when the jaws are brought together, a bit of mucous membrane is nipped and pinched, leading first to ulceration and extreme tenderness, and subsequently to cicatrisation and stiffness of the parts. From insufficient room in the lower jaw, the crown only partially emerges through the gum, the first cusp coming through it, while the hinder cusps remain covered. This produces a terrible pinching of the mucous membrane over the tooth every time the jaws are brought in contact. Another troublesome symptom, often associated with the painful cutting of a lower wisdom-tooth, is spasmodic but continuous contraction of the masseter muscle, so as to keep the jaws nearly closed, and capable of only slight separation. The most distressing result, however, is the suppuration that often attends the difficult eruption of the tooth. Even in ordinary cases, when none of these complications are present, there is often a good deal of diffuse and erratic pain in cutting a wisdom-tooth. It is unnecessary to enter into the treatment, which must be left entirely to the surgeon-dentist.

7. *Hæmorrhage after extraction of teeth* has occasionally proved fatal, and is not very unfrequently a troublesome and even dangerous complication of the operation. In most of the recorded cases, there has been distinct evidence of the existence of the hæmorrhagic diathesis, or, in other words, of a liability to bleeding profusely from the most trivial wounds. No better local treatment can be recommended than that which was suggested by John Hunter nearly a century ago. 'In general, it will be sufficient to stuff the socket with lint, or lint dipped in oil of turpentine, and to apply a compress of lint or a piece of cork thicker than the bodies of the adjacent teeth, so that the teeth in the opposite jaw may keep up a pressure.' Matico and saturated alcoholic solution of tannin may be equally efficacious as styptics, but are not superior to oil of turpentine. In some cases, the extracted tooth has been successfully replaced as a plug. The internal administration of astringents, such as tannin and oil of turpentine, should be combined with the local treatment.

8. The subject of *Tartar* on the teeth has been considered in a special article.

TEFF. See MEADOW GRASS.

TE'FSA, TA'DLA, or **TEDLA,** a town of Morocco, 135 miles north-east of the city of that name, stands in the fertile, well-peopled district of Tadla, on the banks of the Um-er-Beg. It is one of the oldest towns of the country, and its manufactures of woollen cloths and shawls are important. Together with the small town or suburb of Efza, T. contains 11,000 inhabitants, 2000 of whom are Jews.

TEGNER, ESAJAS, a Swedish poet of high reputation, was born in 1782 at Kyrkerud, in the Swedish province of Wermland, and educated at the university of Lund, where he took the degree of M.A. in 1802. In 1805 he was appointed sub-librarian to the university, and lecturer on æsthetics. In 1811, the Academy prize was awarded to T.'s poem of *Svea*, or Sweden, which at once raised him to the rank of one of the most popular writers of his country. Prior to the appearance of this successful poem, he had written several spirited war-songs and national odes, which had attracted the favourable notice of the king and government. In 1812, he became professor of Greek, and at the same time was ordained to the pastoral care of the parish of Stäfje. During the next ten or twelve years of his life, he devoted himself to the prosecution of his clerical duties, and the acquisition of theological learning, with an earnest and unwearying zeal which was scarcely to be expected from his previous indulgence in the pleasures of society, and his natural inclination towards the exhibition of a taste for coarse humour and equivocal puns. During this period, he composed his two famous religious idyls of *Prestvigelsen*, or the 'Consecration of a Priest,' and *Nattvardsbarnen*, or 'The Young Communicants,' and wrote his *Axel*, a poetic romance, which is regarded by some Swedish critics as even superior to his *Frithiof's Saga*, of which the first cantos appeared in a literary journal, edited by the historian Gejer, under the title of the *Iduna*, and conducted under the auspices of the Gothic Society, the leading object of which was to foster national literature, and put down the prevalent taste for the pedantic classical or foreign school of writing. In 1825, T. published the closing parts of *Frithiof's Saga*, which rather errs in the opposite direction, and follows too closely the ancient saga on which the tale is founded. But notwithstanding the inharmonious character of the composition, which may be regarded rather as a collection of many ballads and odes in various metres than as a complete epic, the *Frithiof's Saga* became the most popular poem of Sweden, and attracted to its author the admiration and notice both of his fellow-clergy and of the sovereign, as was evinced in 1824 by the clergy of the diocese of Wexio nominating him for the vacant bishopric, and the king at once appointing him to the see. In his place at the Diet, as a member of the Chamber of the Clergy, he made himself conspicuous for his support of ultra-conservative views, in opposition to the extreme liberal doctrines which he had advocated in early life. His speeches in the Chamber and on numerous other public occasions have a great reputation in Sweden and Norway, and are devoted to the discussion of questions of education, literature, and finance. In 1839, T. was proposed for the archbishopric of Upsala; but in the following year, he was seized with unmistakable symptoms of insanity, which had been strongly manifested in two of his brothers and other members of his family. Although, after a few months' confinement in an asylum, he was able to return to his work, his health soon broke down; and after lingering for many months in a paralytic condition, he died in 1846. His collective works were edited by his son-in-law, Professor Böttiger, and published in 6 volumes (Stock. 1848). All his larger and more popular poems have been translated into German, French, and English; and among the English translations of his *Axel* and *Frithiof*, those by R. G. Latham (1838), G. Stephens (1841), and the American poet Longfellow, are the best.

TEHRA'N, frequently spelled TEHERAN, capital of Persia, and of the province of Irak-Ajemi, 70 miles south of the shore of the Caspian Sea. It stands on a wide, stony plain, dotted here and there with mud-built villages, and pierced with many circular pits, which reach down to the great subterranean water-courses, on which, in this region, the life of animal and plant is altogether dependent. On the north-east runs the lofty range of the Elburz Mountains, rising in Demavend to the height of 22,000 feet above sea-level, and giving dignity to an otherwise tame and

unattractive scene. The town is built almost entirely of mud-houses, packed within a mud-wall 20 feet high, and 4 miles in circumference. The principal buildings are the British and Russian residencies; the bázár of Taki Khan, finished in 1850—1851, at a cost of £30,000; the Ark, or Citadel—in the suburbs—is the Shah's palace, and about 2½ miles north of these, the Castle of the Kajars (Kasr-i-Kajar), the 'Windsor' of the Persian rulers. Carpets are manufactured; and an attempt was made in 1859 to establish a cotton-factory in the vicinity of the city. The total cost of this factory, from the date of its establishment to July 1861, was £136,000, but it had been so grossly mismanaged that the returns were quite inconsiderable. The chief trades are shoemaking and the manufacture of hats and linen goods. Pop. 100,000, but in winter it is considerably more.—In the vicinity of T. are the ruins of Rei, the *Rhages* of Scripture, known in the time of Alexander the Great under the name of *Ragæ*, and the birthplace of Harûn-al-Raschid.—See Eastwick, *A Diplomate's Residence in Persia* (2 vols., Lond. 1864).

TEHUANTEPE'C, a river-port of the south of Mexico, in the territory of the same name, and 10 miles above the mouth of the river Tehuantepec, in the bay also of that name. The inhabitants (14,000) are engaged in manufacturing salt and cotton fabrics, and in indigo-planting. A railroad has been located, though not built, across the isthmus, and a route for a canal of 173 miles has been explored.

TEÏ'DÆ. See MONITOR.

TE I'GITUR, one of the service-books of the Catholic Church. It is properly but an extract from the Roman Missal, and contains the canon of the mass, and certain other portions of the Liturgy which do not vary with the variety of festivals or of the ecclesiastical seasons, but are always the same. It is so called from the first words of the canon, *Te Igitur, Clementissime Pater*. This service-book, as distinct from the missal, was used, and is still used by bishops, prelates, and other dignitaries; and as the 'canon' is the most sacred part of the service, oaths upon the Te Igitur were regarded as especially solemn. The Te Igitur appears to have been used as the ordeal 'of compurgation.'

TEI'GNMOUTH, a seaport, market-town, and favourite watering-place on the south coast of Devonshire, on the north side of the estuary of the Teign. In front, on the sea-side, is the wide esplanade known as the *Den*, formed of a huge bank of sand, accumulated in the course of ages at the river's mouth—one of the chief features of the place. The harbour is safe and commodious, though difficult of entrance, the channel of the river being obstructed by a shifting bar of sand. The chief imports are coal and culm; the exports, granite from Dartmoor and china-clay; there is also a considerable sea and river fishery. T. is connected with Shaldon, on the other side of the river, by a wooden bridge (completed in 1827) of 34 spans, 1671 feet in length, with a swing over the main channel for the passage of ships. The climate is mild and salubrious, and the country around beautiful. It is a station on the South Devon Railway. Pop. (1881) 7100.

TEINDS, the name given in the Law of Scotland to Tithes (q. v.). In Scotland, tithes were not, as in some other countries, considered to be due from the produce of industry generally, but were only paid from the produce of land or cattle. The teinds of corn, called *decimæ garbales*, greater teinds, or parsonage teinds, were generally exigible from all landed property, and originally paid to the rector or parson serving the cure, a small portion being claimed by the bishop. The tithe of the produce of animals, as wool, milk, cheese, was called lesser teind, or vicarage teind, because, where due, it was paid to the vicar; but vicarage teind was only legally exigible where a usage of paying it could be shewn. The teinds, supposed to be due at common law to the incumbent of the parish, had, previously to the Reformation, been largely diverted elsewhere (see COMMENDATORS); in some instances, they had been bestowed on some favourite religious house by the patron, who seemed to consider himself their absolute proprietor; in others, they had been feued to some layman. In many cases the religious house which had acquired the teinds, profited, or at least saved itself from odium, by selling them to the crown or to a lay subject; and not unfrequently the pope, who was viewed as patron of all benefices to which no one else could claim a right of presentation, granted to the lands of churchmen an exemption from the payment of teind. At the Reformation, the church-lands were claimed by the crown; those that had belonged to the religious houses were erected into temporal lordships, whose proprietors, called *Lords of Erection*, or *Titulars*, were nominally burdened with the support of the clergy, by salaries modified out of a third part of the benefices. At the majority of James VI., it was found advisable to check the practice of granting the lands of religious houses to laymen; and the church lands were declared, with certain exceptions, to be inalienably annexed to the crown.

The right to tithes was, in Scotland as elsewhere, originally made effectual by their owner drawing the *ipsa corpora*, separating every tenth sheaf after the crop was reaped. But this proceeding often became an instrument of oppression, as the proprietor was obliged to allow his crop to remain on the ground exposed to all the vicissitudes of the season, until the beneficiary chose to draw his teind; and prior to the Reformation, agreements had become common by which a certain quantity of grain, called *Rental Bolls*, was accepted in full value of teind, while leases were sometimes granted of the teinds for a money payment.

Various not very successful attempts were made during the reign of James VI. to regulate the conflicting interests of heritor and titular, and to provide the clergy with stipends which would not be illusory, out of the teinds of their respective parishes. Charles I., soon after his accession, issued, without the intervention of parliament, a revocation of all appropriations of church lands and teinds made during the two preceding reigns. The powerful barons who were possessors of church property at first menaced resistance, but eventually shewed a desire for compromise, and the parties principally concerned entered into four submissions, in which they accepted his majesty's arbitration. The decrees arbitral pronounced by the king resulted in the establishment of valuations of teinds, and sales of them to the proprietor of the lands, by which the division of the produce between the owner of the land and the owner of the teind was avoided; and the teinds were made available to their utmost extent for the support of the parochial clergy. A commission, appointed to carry out the decrees arbitral, was continued from time to time till the Union, when its authority came to be vested in the Court of Session, as Court of the Commission of Teinds, the same tribunal which still exercises jurisdiction, both judicial and ministerial, in questions relating to teinds. A heritor, and in some circumstances the minister, may pursue an action of valuation of teinds; and the heritor may also insist on purchasing the teinds of his lands when valued, that is, in paying the value of the annuity in a slump sum. The modifying of reasonable stipends to the clergy

out of the teinds of their respective parishes, is one of the functions of the Court of Commission of Teinds. The practice of augmenting stipends after they have once been modified was introduced with some hesitation; confined at first to stipends below the minimum, it afterwards became general; and was recognised by act 48 Geo. III. c. 138, which provides that no stipend can be augmented till 20 years have elapsed from a previous augmentation. By 50 Geo. III. c. 54, it was provided that the minimum annual value of any stipend should be £150; and if such amount cannot be made up by the teinds, it is supplied from the Exchequer. See STIPEND.

The present position of the tithes of Scotland is as follows: In the majority of cases they have been purchased by the proprietors of the respective lands. after the modification of stipends to the ministers, and are held liable to the burden of augmenting those stipends to the extent of their value; in other words, there are no tithes, but part of the rent of the proprietors constitutes minister's stipend, and an additional part is liable to augmentation of stipend. A part of the tithes are in the hands of titulars, also liable to stipend and augmentation—they are, however, no longer drawn in kind, but paid according to valuation, or compounded for in the few cases where they remain unvalued. The teinds which were held before the Reformation by the bishops and other dignified clergy, are in the hands of the crown, liable to augmentation of stipend. The teinds which remained in possession of the parochial clergy, still belong to them, but are commuted; and those belonging to colleges, &c., are paid by composition, but have not been sold to the owners of the lands.

TEJUCIGALPA. See SUPPLEMENT in Vol. X.

TEKELI (more properly, *Tökely*), EMERIC, COUNT, a celebrated Hungarian patriot, was descended from a noble Lutheran family, and was born at the castle of Kasmark, in the county of Zips, in 1656. His father, Count Stephen, had been implicated in the conspiracy of Zriny and Ragotsky to free Hungary from the rule of Austria; and, after his death. and the execution of Zriny, and others, young T. sought an asylum in Poland, where he had large possessions. After vain endeavours to recover from the emperor his patrimonial estates, he repaired to the court of Abaffi, Prince of Transylvania, who put him at the head of an army of 20,000 men, with which, in 1678, he invaded Hungary. Being joined by numbers of the malcontents, he rapidly extended his conquests, made predatory inroads even into Austria, Styria, and Moravia, till Leopold I. was forced (1681) to temporise with the insurgents, and thus gained over a portion of them. But T. distrusting, with good reason, the emperor's sincerity, refused to disarm, and being joined by the Transylvanian prince and the Turks, he was declared by the Sultan Mohammed IV. (1682) king of Upper Hungary, and again recovered most of the country. T. joined Kara Mustapha in his celebrated inroad upon Austria; but after the failure of the expedition many of his followers fell off from him, and his patron the sultan being prejudiced by his enemies against him, he was twice imprisoned by the Turks; and during his detention, Hungary was wholly overrun by the Austrians, and Transylvania separated from the Turkish alliance. T., however, was favoured by a brilliant though ephemeral change of fortune in 1690, when, at the head of a Turkish force, he burst into Transylvania, routed the combined Austrians and natives repeatedly, and woke up the energies of his partisans in Hungary; but the imperialists, under the Markgraf of Baden, routed his allies the Turks at Salankemen (August 19, 1691), and under Prince Eugene of Savoy, so completely demolished them at Zenta (September 11, 1697), that they gladly agreed to the peace of Carlovitz (November 14, 1697), by which all aid to the Hungarian malcontents was withdrawn. From this time, T. lived in retirement in Turkey, at first being munificently entertained by the Turkish government, but afterwards so completely neglected that he was forced to adopt the occupation of a vintner. He died at Constantinople in 1705.—His wife, Helena, the widow of Ragotsky, was celebrated over all Europe for her beauty, but was no less distinguished for her heroic gallantry, as was proved by her obstinate defence of her castle of Mongatz (Hung. *Munkacs*) against an army of imperialists. Forced to surrender, to save the lives of her children and the property of her (Ragotsky's) family, she was afterwards exchanged for an Austrian general whom T. had captured; and joining her husband at the cost of abandoning her children, shared the vicissitudes of his fortune, and died in 1703.

TELAMO'NES (see ATLANTES), statues employed as columns, to support a wall, cornice, &c.

TELEDU (*Mydaus meliceps*), a quadruped of the Weasel family (*Mustelidæ*), a native of the mountains of Java, at an elevation of 7000 feet and upwards; remarkable, like the Skunk (q. v.) of America, for the excessive fetor of a volatile secretion formed in glands situated a little within the rectum, the emission of which is its principal means of defence.

TE'LEGRAM, a communication sent by Telegraph (q. v.). This word, which was coined recently by a writer in the *Times* newspaper, was objected to at the time by Greek scholars as a barbarous formation. According to the law of Greek compounds, *grapho*, compounded with anything but a preposition, becomes *grapheo*; therefore, with *tēle*, it would be *telegrapheo*, the noun from which would be *telegraphēma*. The convenient conciseness of *telegram* has, however, made it triumph over the more correct *telegrapheme*.

TE'LEGRAPH (Gr. *tele*, far off, and *graph-*, to write) is a general name for any means of conveying intelligence other than by voice or writing. The idea of speed is also implied. Alarm-fires (see BEACON), the Semaphore (q. v.), and the Signals (q. v.) used at sea, are among the earlier forms of telegraph. But all other agents are now thrown into the shade by the electric telegraph. The various forms of electric telegraphs in general use are electromagnetic. The signals are given by the deflection of a needle to the right or left, or by mechanism connected with the armature of an electro-magnet, which sways to and fro under the action of the magnet and a counter-spring, or between two opposite electro-magnets. Electric telegraphs are of two kinds—those which merely give passing signals to the observer or listener, and those which permanently record their signals; the former may be called signalling, the latter recording telegraphs. The number of inventions connected with the electric telegraph is almost endless; we shall here content ourselves with giving a mere outline of the working of the telegraph as at present existing on most lines; assuming that the reader is acquainted with the chief facts of Galvanism (q. v.) and electromagnetism. See MAGNETISM. The forms most in use are Morse's Telegraph, and Cooke and Wheatstone's Needle Telegraph. For private use, some form of the magneto-electric dial telegraph is employed. In point of simplicity and certainty, Morse's system cannot be exceeded, and even as regards speed, it stands equal, or nearly so, to the most rapid recorders. We shall therefore give an account of the general arrangements of a telegraph chiefly on Morse's system.

Morse's Recording Instrument, or, as it is shortly called, the 'Morse' or 'Register,' is shewn in fig. 1. L is the line-wire, and E the earth-wire, conveying the current from the distant station. The current thus sent traverses the coils of the electro-magnet, MM', the armature, A, of which is in consequence drawn down. A is attached to the lever *ll'*, moving

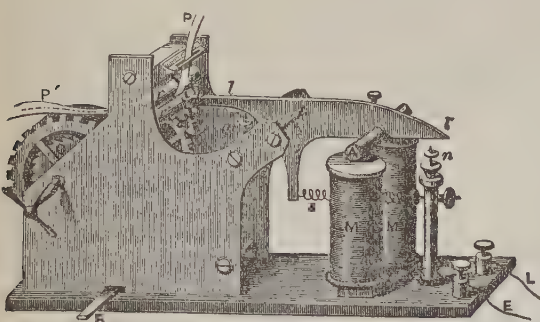

Fig. 1.

round the axis *k*. By the attraction of A, the end *l'* is lowered, and brought against the stud *n*. The armature must not touch the soft iron of the electro-magnet on being drawn down, for if it did, it would stick, and would not be instantly released when the current ceases. When the end *l'* is lowered, the end *l* is raised; *ll'*, at its inner end, carries a steel point or style, *p*, which by the upward motion is brought against a strip of paper, PP', carried towards P' by the rollers *rr'*, set in motion by clock-work, C, quite independently of electricity. The clock-work is liberated or stopped by the switch S. The paper is supplied from a large roll or bobbin, above the instrument, which turns round as the rollers demand. So long as the style is elevated, the paper strip is made by the clock-work to rub against it. A line is thus embossed on its upper surface. To facilitate the doing of this, there is a groove in the upper roller, opposite the style. When the current from the distant station ceases, the lever *ll'* is pulled back to its original position by the spring *s*, and the style falls away from the paper. To prevent it falling too far, another stud, *m*, lies on the other side of the axis. When the circuit is again closed, the style once more marks the paper, and thus the lever keeps oscillating under the opposing actions of the magnetism developed by the transmitted current, and the elasticity of the spring *s*. The time that the style remains elevated, determines the kind of mark on the paper. If it is nearly momentary, a dot is imprinted; for a longer time, a dash. We have thus the combinations of an alphabet in the combination of dots and dashes. Thus, A is a dot and a dash (. —); B, a dash and three dots (— . . .); &c. The alphabet is so arranged that the letters occurring most frequently are most easily signalled; thus, E is one dot; T, one dash. An expert telegrapher can transmit from thirty to forty words a minute by this instrument on a land-line of between 200 and 300 miles. Several modifications of Morse's telegraph have been made, the chief one being the substitution of ink-marking for embossing. The beautiful instruments of Siemens and Halske are of this kind.

A clerk that has been well accustomed to Morse's telegraph, in transcribing, seldom looks to the paper. The mere clicking of the lever becomes a language perfectly intelligible to him. He need therefore only look to the record when he may have heard indistinctly. Sir Charles Bright does away with the recording instrument altogether, and substitutes two bells, one muffled, the other clear, sounded by a hammer oscillating between them. The bells speak a telegraphic language as quick as the clerk can write. It is stated in favour of Bright's system (which is used by the Magnetic Company) that the signals are all as it were dots in Morse's instrument, and so take less time than dots and dashes. Recording instruments are generally considered preferable to instruments which merely signal, as they fix any fault of transmission or copying on the party at fault. Acoustic signalling, again, is preferable to ocular signalling, as a person can hear and write much more easily than see and write.

Transmitting Key.—Let us now transfer our attention to the distant station, to see how the current is transmitted from it. This is done by the transmitting key shewn in fig. 2. A brass lever, *ll*, moves round the axis A. On opposite sides of the axis, two nipples of platinum, *m*, *n*, are soldered to its lower sides. The nipple *m* is called the hammer. Below *n* is the stop anvil, *b*, tipped with platinum, which is in connection with the earth-wire E. Below the hammer, *m*, lies the anvil *a*, the nipple of which is likewise of platinum; *a* is connected by the wire C with one of the poles of the sending battery, generally the copper pole

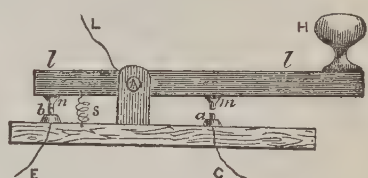

Fig. 2.

When the lever is left to itself, *n* and *b* are in contact under the force of the spring *s*. When the hand presses on the ebonite (insulating) handle H, contact is broken at *n* and *b*, and established at *m* and *a*. Three wires are in connection with the key, E and C just named, and L the line-wire from the distant station connected with the axis pillar, and therefore with the lever. When the key is in the receiving position, that shewn in the figure, the current from the sending station takes the route L, A, *l*, *n*, *b*, E, the Morse, then to earth. When H is pressed down, the key is in the sending position, and transmits the battery current by C, *a*, *m*, A, L, to the distant station. The play of the anvil and hammer need not be more than $\frac{1}{16}$th of an inch. This is more than sufficient for completely breaking the current, and it allows of speedy manipulation.

The Battery.—The batteries employed are in Great Britain almost universally Daniell's. See GALVANISM. Constancy and certainty of action is what is most wanted in the battery, and this Daniell's battery yields. In Germany, Bunsen's battery is also used, charged with diluted sulphuric acid, the carbon being immersed in a mixture of 1 of acid to 10 of water, and the zinc in one of 1 to 20. When batteries have to be moved about much, sand is put in, to keep the liquid from spilling. The number of cells employed varies with the distance, the insulation of the line, and the delicacy of the instruments. The register, as afterwards mentioned, is seldom worked directly by the transmitted current, but by relay. To work a relay

with good insulation, 60 Daniell's cells will suffice for a distance of 300 miles. For less distances, less of course will suffice. For short circuits, where the resistance is small and current strong, small cells soon exhaust themselves, large cells therefore must be used to maintain the supply. Magneto-electricity is also employed as a source of the current. This answers well on short circuits, or for private telegraphs, but experience has proved that the galvanic battery is by far the most advantageous source of electricity for extensive telegraphic work.

How Two Stations are connected together.—The manner in which two stations are 'joined up' on Morse's system is shewn in fig. 3. B and B_1 are

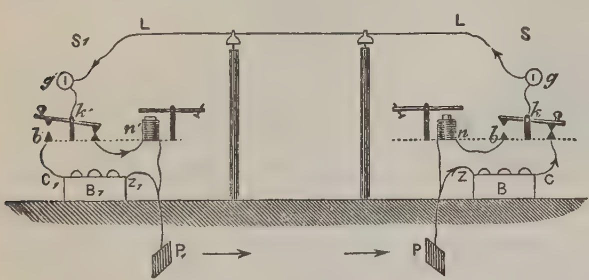

Fig. 3.

the batteries at the stations S, S_1; k, k' are the transmitting keys; n, n', the registers; g, g', the galvanometers; LL the line-wire insulated on posts; P, P_1, the earth-plates. When the key k, at the station S, which is here represented as the sending station, is depressed, the current from the battery B takes the following course. From the copper pole C, of the battery B, it goes to the anvil of k, passes through k to the galvanometer g, which having traversed, it goes into the line LL to the receiving station S_1, traverses the galvanometer, the key k', the coils of the register n'; thence it goes 'to earth' at the plate P_2, returns by the ground to P at the sending station, and thus finally reaches the zinc pole Z of the battery B. At station S, b and n are out of circuit; and at S_1, b' and battery B_1 are out of circuit; n is thrown out of circuit, because its coil offers a resistance equal to several miles of the line-wire, and it is requisite to keep down the resistance to the minimum. If it were in circuit, both registers could print simultaneously, but that is not necessary, one record at the receiving station being enough. The sender would thus have no idea as to whether his message had told or not, did not the motions of the needle of the galvanometer, g, reveal the currents put in circuit. The galvanometer also shews the presence of earth-currents on the line. If k were left to itself, and k' depressed, the station S_1 would then be the sending, and S the receiving station, and the connections would be exactly as shewn in the figure, only at opposite stations.

Suppose the clerk at S wishes to telegraph to S_1, he depresses the key k several times, so as to send a series of dots and dashes giving the name of the station. The attention of S_1 is first arrested by the clicking of the armature of the Morse. He thereupon turns the switch S (fig. 1), and sets the clockwork in motion, and sends back to S that he is ready, and the printing thereupon begins. When both keys are depressed, the whole circuit is broken, so that when both sender and receiver have their hands on their respective keys, no message can be sent. One might fancy that confusion would arise from cross messages, but clerks soon get over this inconvenience, and communicate back and forward with perfect facility. There is a code of working signals to indicate the kind of message, 'repeat,' 'understand,' &c., besides numerous recognised contractions. To arrest the attention of attendants, the current is sometimes made to ring an alarum bell.

The Line.—Telegraphic stations must be united by one insulated wire, either carried over land or under the sea. The insulation of land-lines is insured by attaching the wires to insulators fixed on posts some 20 feet high. The posts are placed at distances corresponding to the number of wires they have to carry. A distance of 80 yards is the ordinary distance for posts sustaining several wires, and 150 yards for those only supporting one. Insulators are of all shapes. Porcelain, though a better conductor than glass, is not so apt to attract moisture, and is the substance generally employed for them. The leakage in a long line, notwithstanding the best insulation, is considerable. The loss at each post is insignificant, but when hundreds or thousands are taken into account it becomes decided, so that merely a fraction of the total current that sets out reaches the earth at the distant station. In rainy, and more especially in misty weather, the insulation suffers much.

The wire most employed for telegraphic circuits is No. 8 ($\frac{1}{8}$th of an inch). The Electric Telegraph Company are beginning to use No. 4 wire on some of their long trunk lines.

A Submarine Line is made by a cable. The core of the cable consists of one wire, or a strand of several wires of copper, as pure as can be got in the market. One solid wire is preferable to a strand of the same diameter in point of conducting power; but a strand is surer; for when one wire is broken at any point, the others still remain to conduct the current; there is no 'breach of continuity.' When the one solid wire gets broken, which not unfrequently occurs without being visible outside, the cable becomes useless. The strand of wire is generally laid up in Chatterton's compound, consisting of gutta-percha and resinous substances. The interstices between the wires are thus filled up, and this makes the cable solid throughout. It not unfrequently happens, when this precaution is not taken, that water, under the great pressure of ocean depths, becomes injected into them. The strand thus laid up, is now included in one or more coatings of gutta-percha, which acts as the insulating protection for the wire. Chatterton's compound is generally put between the layers of gutta-percha. The whole is finally included in a sheathing of iron wire, laid on spirally, to give the cable sufficient strength to withstand the strain of paying out, or that to which it may be subjected by the inequalities of the ocean bed. Between the iron sheathing and the gutta-percha, a layer of tarred yarn is put, which acts as a padding between the two, and improves the insulation of the cable. Not unfrequently the iron wire of the sheathing is also protected from corrosion by tarred hemp. Fig. 4 (full size) shews the construction of the Malta and Alexandria

Fig. 4.

cable, 1330 nautical miles long, and one of the best in operation. The different layers are so far peeled off to shew the construction. C is a strand of seven copper wires, laid in Chatterton's compound; G, three layers of gutta-percha, with Chatterton's compound between each; H, tarred yarn; and I, the eighteen wires constituting the sheathing. The diameter out in the sea is 0·85 of an inch. Near the shore, the sheathing is made much stronger, to meet the danger of accident from the dragging of anchors.

Considerable dispute has arisen as to the best material for insulating marine cables. India-rubber and gutta-percha are the two rival substances. It may be said in favour of gutta-percha, that not one yard of it, when laid, has decayed, and that under ocean pressures, as proved by the Atlantic cable of 1865, its insulating power decidedly improves. In favour of well masticated india-rubber, it is urged that cables, alike in other respects, will, when coated with it instead of gutta-percha, be capable of sending twice the number of words per minute, the specific inductive capacity being so much greater for the latter than for the former substance. On the other hand, india-rubber is not so trustworthy in point of durability, some specimens of it having become treacly after immersion for some time in the sea.

The Earth.—Two wires are not necessary to connect two telegraphic stations, as might be supposed. One wire is quite sufficient, provided its terminations be formed by large plates sunk in the ground, or something equivalent. The plates are generally of copper, and should not offer a surface less than 20 square feet, and they must be buried so deep, that the earth about them never gets dry. The gas and water pipes in a town make an excellent 'earth' (earth connection). The great object in an 'earth' is to put the whole ground in the neighbourhood in connection with the battery pole or line-wire, and much the same precautions must be taken in making an earth for a telegraph as for a Lightning-conductor (q. v.). If the earth is not good, the current, instead of taking the ground as a passage to the distant station, runs into other wires connected with the plate, and leading to where the 'earth' is good. When the 'earths' are good, the current passes through the earth between the two stations, no matter what be the nature of the country it has to pass, plain or mountain, sea or land. The earth-resistance to the current, compared with that of a long line, is next to nothing. The earth not only serves the purpose of a second wire, but of one so thick that its resistance may be left out of account, and thus halves the resistance of the whole circuit. One good 'earth' serves for all the circuits of a telegraphic station.

Return Current—Inductive Embarrassment.—When the line-wire at a distant station is 'cut' (insulated or disconnected with the ground), and is placed in connection with one of the poles of a battery, the other pole of which is to earth, at the instant in which the connection is made, a current flows into the wire, and if the insulation of the line be perfect, almost instantly ceases. The needle of the galvanometer makes a sudden deflection, and then returns to its position of rest. If now, at one turn of a commutator, the battery connection be cut off, and the line be put to earth, the needle deflects momentarily in the opposite way, and the charge given to the wire returns, and goes to earth. This flowing back again of the charge is called the *return current*. In land-lines, the return current is very slight; in submarine cables, it is very marked. The return current shews that a telegraphic line may be charged statically, just like the insulated balls, cylinders, &c., illustrating frictional electricity. A line of telegraph may be looked upon as a Leyden jar, the wire as the inner coating, the air or gutta-percha as the glass or dielectric, and the earth or sea as the outer coating. A coil of submarine cable, immersed in a trough of water when the core is insulated, may be charged and discharged exactly as a Leyden jar, the water being the outer coating. The return current is most marked in long lines. In such, it is not necessary to 'cut' the wire, the great resistance of the long wire being equivalent to partial insulation; the return current being, however, much smaller in extent.

The statical charge, of which a line of telegraph is thus capable, shews that the electric force not only tends to propagate itself longitudinally, but laterally. The effect of lateral induction is to retard the time of delivery of a signal, and to prolong it so that although it is a momentary signal at starting, it becomes a prolonged signal at its destination. Wheatstone's calculation (see ELECTRICITY) gives a velocity of 288,000 miles per second for electric discharge. If signals were propagated at this rate, the time elapsing between the sending and delivering of a current, even on a line extending over one half the circumference of the globe, would be inappreciable. But in aërial lines of land telegraphs, even only a few hundred miles in length, there is evidence that electricity does not propagate itself at anything like that speed; and in submarine cables, the velocity scarcely reaches thousands of miles per second. The mere slowing of the message would not matter so much, provided the signals, when they reached their destination, were told out as they were sent. But they are not. Each signal at the receiving station takes a longer time to leave the line than it did to enter it. Hence, in a very long land-line, or in a cable, if the sender transmitted at the same rate as he does in short circuits, the signals would run into each other at the receiving station, and be undistinguishable. Time must be given to allow each signal to ooze out of the cable before another is sent. The effects of lateral induction on the transmission of telegraphic currents constitute what is termed *inductive embarrassment.*

According to Professor Thomson, the maximum speed attainable on an aërial land-line of 2000 nautical miles in length, and consisting of an iron wire one-fourth of an inch in diameter, would be 20 words per minute. The same authority has established, that *the retardation increases with the square of the length of the line.*

The insulation of submarine cables is almost perfect, so that inductive embarrassment must not be confounded with leakage. The insulation of the Atlantic cable of 1865 was so perfect, that when 'cut' and charged, it would have fallen from charge to half-charge in 15 minutes.

Earth-currents.—These are very unwelcome visitors in telegraphic offices. They get into the circuit no one knows how. They flow sometimes in one direction, sometimes in another, change rapidly, and are frequently so strong as to render the line for the time quite useless. They seem to come as often from the wire as from the earth. They occur simultaneously with magnetic storms. The famous magnetic storm that raged on August 2, 1865, at the same time that the Atlantic cable ceased to act, was accompanied by earth-currents so strong that the astronomer-royal considered it impossible, even if the cable had been perfect, to have signalled through it. The only remedy for earth-currents is to do away with the earth-circuit and put two wires to the same place in one circuit. Although the earth-current runs equally strong in

both, the two wires bring it to opposite ends of the instruments at the stations, and its effect is thereby neutralised. This, of course, can only be done where two wires exist. Little or nothing is as yet known of the laws regulating such currents.

Relay (Ger. *Uebertrāger*).—Hitherto, we have supposed that the recording instrument of Morse is worked directly by the line-current. This is only done on short circuits, generally less than 50 miles. On long circuits, direct working could only be accomplished by an enormous sending-battery. The loss by leakage on the way is very considerable, so that a current strong at starting loses greatly before it reaches the station intended; besides, the leakage becomes all the greater the greater the number of cells employed, or the greater the tension of the battery. It is found a much better arrangement to get the 'Morse' worked by a local current, which may be made as strong as requisite without any loss, and to include a very delicate instrument in the line-circuit, which has only to make or break the local circuit. Such an instrument is called a relay, the principle of the action of which is shewn in fig. 5. Instead of the electro-magnet of the register

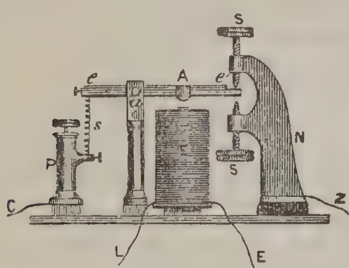

Fig. 5.

being in the line-circuit, the electro-magnet, E, of the relay is included. The coil is long, and of thin wire, and a very faint current is sufficient to develop magnetism in the core. The line-current passes through the coils of E just as it is represented doing through that of the Morse in fig. 1. The armature of the relay, A, is attached to a lever, *ee'*, moving round the axis *a*. When a current is sent through the coil, the lever is drawn down, and the end *e'* rests on the screw S. When there is no current, the elasticity of the spring *s* brings it back against the screw S'. The spring, *s*, is so adjusted that the play of *ee'* may be made as easy or stiff as the strength of the line-current requires. The pillars N and P are connected with the poles of the local battery. The metal spring *s* places the lever *ee'* in conducting connection with P. The poles of the battery may therefore be taken to be the screw S, and the end *e'* of the lever. When these are in contact, the local current flows, and it stops when *e'* is brought back against the insulated screw S'. The Morse is included in the local circuit. When a current comes from the sending-station, the armature, A, is attracted, *e'* falls on S, the local circuit is closed, and the Morse begins to print. When the current ceases, *e'* falls on S', and the style of the Morse is withdrawn from the paper. The effect is thus the same as if the line-current printed, and not the local current. By this means, a current that would have no effect on the Morse, can complete the local circuit, and print most legibly.

How Several Stations are connected in One Circuit.—This is effected in three ways—by an *open circuit* (Ger. *Arbeitsstrom*), by a *closed circuit* (Ger. *Ruhestrom*), and by *translation*. In all of these, each station may telegraph simultaneously to all the stations in the circuit, and if the message concerns them all, a record may be printed at each station. When a station wishes to telegraph to another, it keeps signalling the name till the station in question signals back that he is ready. The others, finding that the message does not concern them, leave the two concerned in possession of the circuit.

The arrangement of an intermediate station in an open circuit is shewn in fig. 6. L_1 and L_2 are the wires from the terminal stations; R is the relay; the rest mean the same as in fig. 3. The station is represented as receiving. The line-current passes through the key, the relay R, and goes on to L_2. The relay sets the local battery and the register in operation. The line-current is brought into the station, and led out without being affected. Electrically, it is the same as if it had gone on in the air direct from L_1 to L_2. When the station sends, the key is depressed. The current goes from C into the line L_1, is earthed at the one terminal station, leaves the earth at the other, and returns to Z by L_2. The battery here has no 'earth,' as at the terminal stations, the arrangement of which is as in fig. 3. An 'earth,' however, is generally put at each station, so that it may be worked as a terminal station if required. R at sending is out of circuit. According to this plan, every station must have a battery as strong as the terminal stations. In the closed circuit, no battery is needed at the intermediate station. If the battery and its connections be removed, fig. 6 gives the arrangement in a closed circuit. The battery may be placed only at one terminal station, or it may be divided into two, and a half put at each end, both, however, being joined up to act with, not against each other. The circuit is closed when no one operates, so that a current constantly flows. The keys breaking the connections stop it for the time. The relays act negatively, making the Morse print when there is no line-current, and be at rest when it flows. If S' in the relay (fig. 5) were uninsulated, and S insulated, it would act in a closed circuit. The advantage of the closed circuit is, that the batteries which require considerable attention are confined to the terminal stations, where they can best be cared for. Besides, little or no adjustment is needed for the relays. In the closed circuit, all the relays are in circuit at once. Open and closed circuits are used in lines where a number of smaller towns are joined together, the business of all of them being no more than sufficient to keep the line working. They are, for short distances, seldom more than 200 or 300 miles.

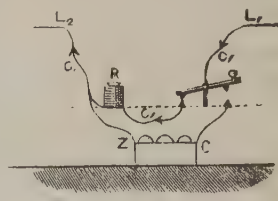

Fig. 6.

When two stations, say 500 miles apart, are to be connected by telegraph, it is seldom done by a direct line, it being found more efficient to transmit to a half-way station, and thence to retransmit to the end one. The retransmission is effected not by manipulative skill, but by mechanical contrivance, so that, while the half-way station may read the message sent, no time is lost in the transmission, and the two end stations and the intermediate station communicate with each other as readily as if they were in an open or closed circuit. This mechanical retransmission is called *translation*. It is effected by making the lever of the register act as a relay in transmitting a message to the next

station. The system, to be fully explained, would require more detail than we can here give to it. We shall only shew how translation can be effected, leaving out of account how all the stations can communicate as in one circuit. We also suppose, for the sake of simplicity, that no relay is needed, and that we are dealing with a direct working register. The current, C_1 (fig. 7), from the sending-station enters the coil of the register M, and goes thence to earth P, and returns as shewn by arrow C_1. The register may record or not, according to the message, but its doing so or not in no way interferes with translation. The copper pole C, of the battery CZ, is connected with the lever *ll′* of the register, and the zinc pole is to earth. When the lever is drawn down by the current C_1, it strikes against the point at the top of the pillar *p*, that checks its motion. The pillar *p* is joined to line L_2, running to the further station, and when the lever falls, a second circuit—viz., that of the battery CZ—is closed, in which C, the lever, the pillar, L_2, the further station, the earth, P, and Z are all included. Thus, as *ll′* prints at the intermediate station, it at the same time sends a new printing-current to the next. When it ceases to print, so does the register at the distant station. It is in this way that parliamentary news is transmitted simultaneously to all the important towns lying between London and Aberdeen. At the shore ends of submarine cables, there is always a translating apparatus. This allows the cable to be worked by a battery suited to it, without loss of time in making it a special circuit.

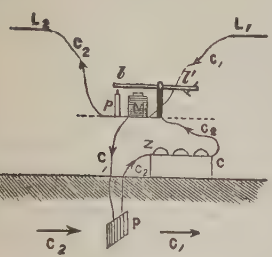

Fig. 7.

Cooke and Wheatstone's Needle Semaphore.—This

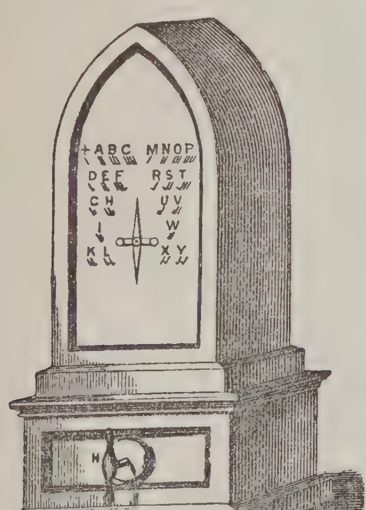

Fig. 8.

consists of an upright galvanometer, with the astatic needles loaded at the lower end, to keep them, when not acted on, in a vertical position. A front view of the single-needle instrument is given in fig. 8. One needle moves within the coil, and the other on the face of the dial. It is the dial needle which acts as the indicator. The alphabetical code is made up by combinations of the right and left deflections of the needle. The old alphabet is given in fig. 8. A is made by two left deflections; M by one right; D by one right, then one left; R by one left, then one right; G by two right, and one left; and so on. The short arm indicates which beat is made first, and the long that made second. The Electric and United Kingdom Companies have adopted an alphabet corresponding to Morse's code, a right-hand deflection corresponding to a dash, and a left-hand deflection to a dot. The instrument is so arranged, that when the handle, H, stands erect, the whole is in the receiving state. When the handle turns to the right or left, the instrument sends, and the needle deflects accordingly to the left or right at both the sending and receiving stations.

Historical Sketch.—Ampère suggested as early as the year 1820 the employment of a galvanometer, lines of wire, and a battery as a means of telegraphing. In 1832, Dr Joseph Henry (q. v. in SUPPLEMENT) first established the fact that mechanical effects could be produced by a galvanic current at a distance operating upon a magnet or needle, and that the telegraph was therefore possible. Gauss and Weber at Göttingen in 1833 suspended about a mile of wire in the air to aid their magnetic operations, using a reflecting galvanometer, with the suspended magnet in the centre of a coil of wire forming part of the circuit. Their alphabet was made up of combinations of right and left reflections. This apparatus, the first ever employed for practical telegraphy, has lately, in the hands of Sir William Thomson, become the most sensitive of all telegraphic instruments. His reflecting galvanometer is the only instrument at present by which a cable 2000 miles long can be worked with low tension (two or three Daniell's cells). It consists of a magnetic needle, only one grain and a half in weight, suspended by a thread without torsion within a sensitive galvanometer coil. A tiny mirror is attached to the magnet, by which a beam of light directed against it is reflected upon a scale at some distance. When no current passes, the reflected ray lights up the zero-point of the scale. When a current is sent, it travels to the right or left according to the message. If earth-currents turn the reflected ray to a point right or left of this true zero, this point may be taken as the zero for the time being, and signals may be sent right and left of it as before. Gauss and Weber's telegraph was merely looked on as a scientific curiosity. It was not till the year 1837 that the electric telegraph promised to become a matter of general and practical importance. In that year, three systems of telegraphy of independent origin were tried, and so nearly at the same time, that all three lay claim to priority. In June of that year, Cooke and Wheatstone patented a five-needle semaphore, or signal apparatus, which was put in action on the Great Western Railway soon afterwards. These inventors have undoubtedly the credit of being the first to construct a line of magneto-semaphoric signals for general purposes. Their lines consisted of underground insulated wires. Cooke derived his first idea from a lecture he heard at Heidelberg given by Professor Munke, in which was described Baron von Schilling's horizontal needle telegraph, said to have been constructed as early as 1832 or 1833. In July of 1837, Steinheil, at Munich, stretched telegraphic wires over the houses of the town from the Physical Cabinet of the Academy to the Observatory of Bogenhausen, about three miles off. He telegraphed in three ways—by the

deflections of a needle, by the sounding of two bells of different tones, and by printing a strip of paper. In October of 1837, Professor Morse exhibited his automatic recording telegraph, 1½ miles in extent. Morse's system is in universal use, except in Great Britain. Steinheil's printing system is also extensively employed, more especially on the continent. Steinheil's system of printing is different from Morse's; positive and negative currents print each a different mark. In Morse's system, either current prints indifferently. Steinheil's alphabet consists of dots to the right and left of the strip of paper. It is thought that the telegraphing by right and left dots can be done more quickly than dots and dashes in a line. In 1838, Steinheil discovered the efficacy of the earth-circuit, and the need of only one wire. To Steinheil also belongs the merit of being the first to stretch wires in air on insulating supports, and to shew the applicability of magneto-electricity to telegraphic purposes. Cooke and Wheatstone patented the first step-by-step telegraph in 1840. This invention was worked by voltaic or magneto-electricity. In 1846, Bain patented his electro-chemical telegraph. In this instrument, a piece of paper, moistened with an acidulated solution of ferrocyanide of potassium, is laid on a revolving plate of metal under a steel point pressing gently on it. As the current passes through the paper from the point to the plate, it marks it with blue dots or dashes, as in Morse's system. No relay is needed. This system, to all appearance one of the most simple and delicate, has never come into permanent use. Morse's telegraph did not come into practical use till 1844, when it was used on the first American line between Washington and Baltimore. The first successful submarine cable was laid between Dover and Calais in 1851. Faraday first announced the effects of lateral induction in 1854. The telegraph was completed by the Persian Gulf to India in 1865. The first Atlantic cable was projected by Cyrus W. Field, of New York, and was successfully laid August 5 1858, after a failure in the previous year, and ceased to work on September 1 of the same year, having transmitted 400 messages. The energy of Field restored confidence, and another cable was made and laid down in July 1865, but after 1200 miles were deposited it was lost. In 1866 another was made, and in July it was successfully laid down. In August the lost cable was found and spliced, and carried to the western shore, and thus two Atlantic cables were finally established. A French cable was completed, July 23 1869, from Brest to the island of St Pierre, near the Gulf of St Lawrence, and continued to Duxbury, Mass. During the month of March 1871, 12,547 messages were transmitted across the Atlantic, or about 405 per day. The companies, in 1870, paid from 7 to 9 per cent. dividends, but laid by no reserve fund. In 1865 the cable line overland through Alaska and Siberia was projected, but on the successful raising and operating of the transatlantic cable it was abandoned.

Statistics.—There are two systems of telegraphy—the government, now in operation in every state in Europe with very decided advantage, and the corporate, which is still in operation in the United States. The first seeks the interest of the people, the last of the stockholders primarily and of the people secondarily. Low rates ot despatch consequently prevail in Europe, and high ones in America. In France, there are 1700 telegraph stations, with 24,000 miles of line and 100,000 miles of wire, which transmit 4,000,000 messages a year, at an average rate of 10 cents per 20 words to all parts of the country. Prussia in 1867 had 45,272 miles of wire in operation, and transmitted telegrams at an average rate of 22½ cents for 20 words. In Belgium and Switzerland, messages are sent at a charge of 10 cents for 20 words. In the former state, a reduction of 50 per cent. in the tariff charges has produced an increase in the despatches of 85 per cent. In Norway, the telegraph is applied to a novel use. The fishing grounds extend about 1200 miles along the coast, and, by means of semaphores and movable telegraph offices, the approach of fish arriving in immense shoals is instantly signalled inland and elsewhere, greatly to the advantage of her 40,000 fishermen. In 1866, Great Britain had 15,378 miles of line in operation, and 73,361 miles of wire, which cost £2,413,582. The conduct of the telegraph in Great Britain proving unfavourable to the public interests, the government assumed the control of it in February 1870, and has conducted it with eminent success. The low tariff of charges, vast increase of offices, and general regard for the public convenience have proved the wisdom of the change. The total amount of stock created under the telegraph act of 1869 for their purchase during 1870, was $37,000,000. The gross earnings for 1870 amounted to $3,992,900, and the working expense to $2,350,000. In 1868, a number of important treaties were concluded between most of the states of continental Europe for the purpose of extending and popularising telegraphic correspondence. In the United States there are about 5000 telegraph stations, 75,000 miles of line, 7000 employees, and over 11,500,000 messages annually; of this the Western Union Company own 52,099 miles of line and 104,000 miles of wire, which probably cost about $10,000,000, though they have been nominally valued at $45,700,000; the remaining lines probably about $3,000,000. The Western Union Company employ about 6000 operators, and receive annually about $5,000,000. The cost of American despatches averages 71 cents—in nine countries in Europe, 40 cents. While to the genius of one American citizen, and the industry and enterprise of another, the world is indebted for the practical introduction of the electric telegraph, the United States is far behind the states of Europe in furnishing the people with a cheap, swift, reliable, and comprehensive system of telegraphy. A committee of Congress, on July 5 1870, recommended the incorporation of a postal telegraph company, to be under the control of the government, in imitation of the British postal telegraph system, and a bill was prepared, which has not yet become a law. See Catalogue of Works on Telegraphy in *Examination of Telegraphic Apparatus*, by S. F. B. Morse, in *Rep. of Amer. Com. to Paris Exhib.* 1867, Washington, 1869.

The continent of Europe, from one end to the other, forms one vast network of telegraphic lines. The stations in Great Britain, numbering about 4000, are in connection with that number (the principal stations) on the continent. Europe and Africa are connected, through Corsica, Sardinia, and Sicily, by a cable with Algiers, and by another touching at Malta with Alexandria. Into Asia the European system penetrates by St Petersburg as far as Irkutsk in Siberia, and by Constantinople and the Persian Gulf to Calcutta. In France, the tariff adopted is ½ franc for messages within the department, and 1 franc to other parts of the country. Autographic messages sent by Caselli's telegraph, which was adopted in 1865, are charged at the rate of 20 centimes for each square centimètre. In the United States, before the establishment of the British postal system, the telegraph was more a matter of every-day use than in Great Britain. Compared with the population, America then sent almost three times the number of telegrams sent in Great Britain. There is a line of telegraph between New York and San Francisco, across the continent, connecting the shores of the Atlantic and Pacific. On the day of the funeral of President Lincoln, 75,000 words were telegraphed from Washington to New York, 70,000 of which were sent between 7 o'clock at night and 20 minutes past 1 in the morning. See *Exam-*

ption of Telegraphic Apparatus, &c. at the Paris Exhib. 1867, by S. F. B. Morse, Washington, 1869.

TELE'MACHUS, son of Odysseus (see ULYSSES) and Penelope (q. v.), was an infant when his father left home to join in the war against Troy, but during the latter's long absence of about 20 years grew into manhood. At the instigation and under the guidance of Athene (Minerva), who had assumed the appearance of Mentēs (commonly known as Mentor, Lat. 'the thoughtful one'), king of the Taphians, his father's dearest friend, T. set out in search of his long-lost sire, after having vainly endeavoured to eject his mother's troublesome suitors from the house. Having visited Pylos and Sparta, at both of which places he was most hospitably entertained, T. returned home to Ithaca, where he found his father in the guise of a beggar, living with the swineherd Eumæus. After mutual recognition, father and son proceeded to slay the suitors.—In modern times, T. is known chiefly as the hero of Fénelon's (q. v.) romance, *Télémaque*, which is an account of the adventures that he is supposed to have met with in the search after his father, and under the guidance of Mentor, who acts to him the part of 'guide, philosopher, and friend.' This work was once very popular as a school-book both in Britain and on the continent.

TELEO'LOGY, the doctrine of ends, is derived from the Greek *telos*, an end, a word brought into philosophic discussion by Aristotle. The idea of an end entered into the Aristotelian conception of physical science, but more properly into ethical science or morality. All the ancient systems of morality, from Socrates downward, correctly regarded it as a *practical* science; they started with the inquiry, 'What is the proper and final end of all human conduct?' and the answer given by each school was the characteristic doctrine of the school. Aristotle answered, 'Happiness, in a peculiar sense;' the Stoics said, 'A regard to the whole universe of being;' the Epicureans, 'Pleasure and the absence of pain.' John Stuart Mill, in the concluding chapter of his *Logic*, entitled, 'The Logic of Practice, or Art; including Morality and Polity,' adopts the ancient point of view, and observes that there should be a science of ends, or a reasoned statement of the final purpose of all human action; for this science he suggests the name Teleology, remarking that it corresponds to what the Germans call the practical reason. There would be comprehended under it, the art of living or happiness, taste or the beautiful, morality, and politics. See CIVILISATION. The word Teleology is applied to the argument from design in proof of the Deity. This is in keeping with Aristotle's employment of the word in physics. When a natural philosopher assigns the purpose or end of any natural arrangement, as the offensive or defensive weapons of an animal, he is said to give a teleological explanation.

TELEOSAU'RUS, a genus of fossil crocodiles, the remains of which occur in the Oolitic rocks. They are found associated with marine fossils, and the peculiar modification of their skeleton seems to have specially fitted them for an aquatic life. Both surfaces of the vertebræ were slightly concave, the hind-legs were large and strong, and the anterior portion of the body gradually tapered into the long and slender jaws, giving the animal the aspect of the gavial of the Ganges, only the jaws were more attenuated, and the nasal aperture, instead of being oblique, opened vertically on the truncated end of the upper mandible. The jaws were armed with numerous equal and slender teeth, slightly recurved, and admirably adapted for the capture of fishes, with which the Oolitic seas abounded. No less than twenty species have been described, and these present so many striking differences, that they have been arranged under six sub-genera.

TE'LEPHONE. This is an instrument invented by Reis of Frankfurt, in 1861, to telegraph musical sounds. It is well known that when a rod of soft iron is placed in a coil of wire, it is magnetised when a current is sent through the coil, and demagnetised when the current ceases. A distinct sound like a tick accompanies the demagnetisation. There is apparently no limit to the rapidity with which this can be obtained. Each break in the coil circuit produces this tick, however rapid one may follow the other. Reis places an iron rod and a coil at the receiving station; and by means of a tight membrane made to vibrate by the sound of the human voice or other musical instrument at the sending stations, he produces as many interruptions in the circuit and ticks of the rod as there are vibrations in the various notes. The reproduced notes, though of the same pitch, are not of the same quality as the transmitting notes. They are very faint, and resemble the sound of a toy trumpet.

TELE'PHORUS, a genus of coleopterous insects, of the sub-order *Pentamera*, and section *Serricornes*. The body is long, narrow, depressed, soft, and somewhat flexible. The species are numerous, and some of them abound in Great Britain and the state of Pennsylvania in summer, chiefly in meadows and pastures. The larvæ dwell in moist earth, and devour small insects and their larvæ. The perfect insect feeds on similar food.

TELE'RPETON, a remarkable genus of fossil reptiles, the relics of which have been found in fine-grained whitish sandstone quarried at Cummingston, near Elgin. A single specimen was long all that had been detected; but a second is now known. The first exhibits the skeleton complete, with the exception of the termination of the tail, but the bones have disappeared, and left only the casts as dark-coloured cavities in the pale gray rock. Nearly perfect casts of their form were taken by Dr G. Mantell from these hollow casts. The impressions are so well defined as clearly to shew that there were twenty-six vertebræ between the skull and the sacrum, two sacral vertebræ, and the portion of the tail preserved on the slab consists of thirteen others. The ribs, of which there are twenty-one pair, are very slender; they are short near the head, but quickly lengthen as they leave it. The reptilian nature of this fossil is evident. By Dr Mantell it was considered to be a batrachian, and described as *Telerpeton Elginense;* but Professor Owen has more correctly referred it to the lacertine type, because of the numerous ribs, the structure of the sacrum, and the form of the pelvis. He has named it *Leptopleuron lacertium.*

In the same quarry where it was found, the foot-prints of an animal with a stride of about four inches have been found, and it is very probable that these were produced by the *Telerpeton*, which was nearly five inches long.

This little reptile derives its great geological importance from its reputed antiquity. The rock quarried at Cummingston was referred to the Old Red Sandstone measures, and for several years the *Telerpeton* was looked upon as the earliest quadruped that the geologist had discovered. Its great antiquity has, however, been disproven, because other reptilian remains found in the same beds are allied to Triassic forms, and Huxley has shewn it to be related to other Triassic reptiles of Europe, which he regards as *Lacertilia.* Cope has proven that all these Triassic forms belong to the order *Rhynchocephalia*,

which has an existing representative in the *Sphenodon* of New Zealand.

TE'LESCOPE (Gr. *tēle-skopos*, far-seeing) consists essentially of a lens or mirror, to form, within our reach, an image of a distant object; and a Microscope (q. v.), to examine this image in detail. Its invention is ascribed to various individuals living about the end of the 16th c.; but there is no doubt that Galilei (q. v.) was the first to apply it to any purpose other than the gratification of mere curiosity.

The space at our disposal will not allow of our entering into any minute details, so we propose to give, *first*, a general idea of the mode in which a telescope acts, in the course of which we shall incidentally shew how the magnifying power and the brightness of the image depend on the dimensions of the various parts of the instrument; *second*, to point out the various causes of imperfection, which in all telescopes are unavoidable, and how these are reduced to as small an amount as possible; *third*, to mention the most important of the many forms which have been devised, and the processes by which these delicate instruments are practically constructed.

When a lens is employed, as in a camera obscura, to form an image of an object, as AB in fig. 1,

Fig. 1.

the distance of the image from the lens depends on the focal length of the lens, and also on the distance of the object. Practically, with telescopes, the distance of the image from the lens is, on account of the remoteness of the object, the focal length of the lens. Also the image of any point, A, of the object lies in the prolongation of the line joining A with the centre, C, of the lens. Join AC, and produce it to *a*, C*a* being made equal to the focal length of the lens, *a* is the point at which the

Fig. 2.

image of A is formed. Similarly at *b* the image of B is formed. Thus the image is *inverted;* and, seen from C, the image and the object subtend equal angles, or look equally large. When a concave mirror forms an image, the effect is as in fig. 2, where C is now the centre of the sphere of which the mirror is a portion. When the object, AB, is at a great distance, the image, *ab*, is *inverted*, and is formed half way between C and the mirror. As before, object and image subtend equal angles at C. In order to see these images, the eye must be placed at some such point as E in each of the figures.

So much for the formation *within our reach* of an image of a distant body. We must next shew the action of a lens when employed to magnify this image. When an object, as *ab* in fig. 3, is placed rather nearer to a lens than its focal length, rays which pass from the object through the lens appear to have come, not from the object, but from an enlarged image as $\alpha\beta$, at a greater distance from the lens—but subtending, as before, the same angle at the centre, *c*, of the lens. In practice, the lens is so adjusted as to form the image, $\alpha\beta$, at a distance of about ten inches from *c*, in which case the eye sees it most distinctly, and the distance of *ab* from the lens is then (practically) the focal length of the lens.

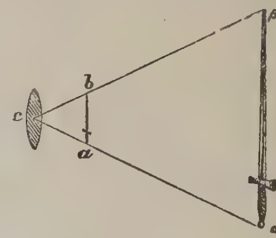

Fig. 3.

We now combine the first and third diagrams, and we have the *Common Astronomical Telescope.* The magnifying power is obviously to be measured by the increase in the angle which is subtended by the image, $\alpha\beta$ (fig. 4), over that which is subtended by the object, AB. The angle at C is the measure of the apparent size of the object; that at *c*, of the apparent size of the image. And it is easy to see from the quadrilateral C*acb* in the figure that these angles are inversely as the sides C*a* and *ac*. (For instance, if C*a* have six times the length of *ac*, the angle at C will be only one-sixth of that at *c*.) Hence the magnifying power is to be found by dividing the focal length of the object-lens by that of the eye-lens. In practice, the lenses are so mounted in tubes that their distance may be increased or diminished at pleasure. When the object, AB, comes nearer the observer

Fig. 4.

its image, *ab*, is formed *further* from the lens C. Hence, for near objects, the telescope requires to be pulled out. Again, the distance of most distinct vision differs for different people, so that even when AB is at a fixed distance, short-sighted and long-sighted eyes require the eye-lens to be removed from, or advanced to, *ab*, so that for each eye $a\beta$ may be formed at the distance at which it can be most distinctly seen.

To estimate the relative brightness of the image

and object, suppose, for simplicity, all the light which enters the telescope from the object to reach the eye. Then the quantity of light which enters the eye from the image, is greater than that which would enter the unaided eye from the object, in the ratio of the aperture of the object-glass, C, to the aperture of the pupil of the eye. But it is spread over a magnified image. If the image be as much larger than the object as the object-glass is larger than the pupil of the eye, the object and image will appear equally bright. Taking the aperture of the pupil as $\frac{1}{10}$th inch, the object-lens would require an aperture of 10 inches, with a magnifying power of 100 times, in order that brightness should not be lost. Practically, the most formidable difficulty in attaining very high magnifying powers, is that due to the enormous sizes of lenses and mirrors which are required to give the necessary brightness to the enlarged image. It is easy to see that it is impossible to render the final image brighter than the object, by any increase of dimensions in the object-lens.

After what we have said about the common astronomical telescope, the reader will have no difficulty, from a combination of figures 2 and 3, in understanding the construction of the Newtonian or Herschelian reflecting telescope.

We proceed to the second part of our proposed scheme of treatment of the subject, viz., the unavoidable imperfections of the telescope, and their reduction to a minimum.

In the first place, then, even with a mirror—where we are not annoyed by the breaking up of white light into its component colours, since the Law of Reflection (q. v.) is the same for all rays—it is impossible to form a perfectly sharp image of more than *one* definite point at a time. In order to do even this, the mirror must be formed as part of the prolate spheroid produced by the rotation, about its longer axis, of an Ellipse (q. v.), one of whose foci is the object-point, the other the image. If the object-point be, like a star, practically at an infinite distance, the requisite form of the mirror is that formed by the rotation of a Parabola (q. v.) about its axis. The axis of the mirror must then be directed to the object-point, and all rays from it will, after reflection, pass accurately through the focus. But this is not strictly true for any other object-point in the field of view, although so nearly true that no inconvenience is practically found to result from it. But, if the mirror used be part of a sphere, no point can be found such that rays diverging from it shall all be brought after reflection accurately to one point of the image; and this defect, called *Spherical Aberration*, increases proportionally to the surfaces of the mirror; so that by increasing that surface, for the attainment of brightness, we increase proportionally the indistinctness of the image. To give an idea of the delicate manipulation required in the construction of a reflecting telescope, we take the case of a speculum of 4 feet aperture and 40 feet focus, as calculated by Sir J. Herschel. If this be first ground to a truly spherical form, it must have a radius of 80 feet, as we have seen above. Now, such a mirror will give a very indistinct image, even under the most favourable circumstances; yet to grind it to the parabolic form, which is practically perfect, leaving the middle untouched, and grinding more and more away from its surface as we proceed outwards to the edges, even at the edges we have to remove a film of metal of only the $\frac{1}{21,333}$d part of an inch, somewhere about the $\frac{1}{100}$th part of the thickness of the paper on which this is printed!

Lenses, whether the object-lens or the eye-lens, have this defect also; but, as a rule, the spherical aberration in lenses is almost negligible compared with *Chromatic Aberration*, which arises from the different refrangibilities (see REFRACTION) of the various coloured rays; and leads to the formation, by a lens, of a separate image of a bright object for each coloured ray. The remedy consists in *achromatising* (see ACHROMATIC, REFRACTION) the lens—i. e., forming it of two or more lenses of different kinds of glass—so that the colours, separated by one, shall be reunited by the others. With a double achromatic lens, in which a convex lens of crown-glass is united to a concave of flint-glass, the focal lengths of the separate lenses can be easily adjusted so as to bring, when in combination, any two assigned rays of the Spectrum (q. v.) simultaneously to a focus; and, by a judicious selection of these two rays, we may reduce the consequences of irrationality of dispersion (see REFRACTION) to a minimum. But this is not all. To construct a lens of a given material which shall have a given focal length, is an *indeterminate* problem; we may assign the curvature of either surface at pleasure, and then that of the other is definite, and can be calculated. Thus, the achromatism of a double-lens can be secured in an infinite variety of ways, and we may impose further conditions; i. e., that the curvatures of the convex and concave surfaces shall be adjusted so as to destroy as far as possible the spherical aberration. Other imperfections, such as those due to DIFFRACTION (q. v.), &c., cannot be here more than alluded to, as they do not admit, within any reasonable limits, of being popularly explained. Nor can we enter upon questions connected with the correction of chromatic and spherical aberrations in eye-pieces, which is effected by the combination of two or more lenses (generally of the *same* material) placed at a certain distance from each other. We may only mention that the defect (for terrestrial purposes) of the common astronomical telescope, the inversion of the image, is overcome by combining two such telescopes, the smaller to examine the image formed by the larger, and therefore to reinvert it. This practically comes to constructing the eye-piece of three lenses at a distance from each other; though, for greater distinctness, four are usually employed.

In the earliest, or Galilean, telescope, the eye-lens is concave; a construction only now used in opera-glasses. It has far less chromatic and spherical aberration than the common astronomical telescope, and is shorter, since the distance between the lenses is the *difference*, not the *sum* of their focal lengths; but it has a very serious defect in the smallness of its field of view. This can only be enlarged, as in opera-glasses, by making the diameter of the object-lens disproportionately great.

Before the discovery of the possibility of forming an achromatic lens, Huyghens, Cassini, and others, had endeavoured, by enormously increasing the focal length of the object-glass of the common astronomical telescope in proportion to its diameter, to get rid as far as possible of chromatic aberration. This was called the *aërial* telescope, as the object and eye lenses were mounted separately on stands; the tube (which would have been 100, 200, or even 600 feet long) being dispensed with. Valuable work was done with some of these telescopes, of 125 feet focus, but the longer ones proved unmanageable. The principle involved in these constructions is, practically, the throwing the magnifying power more on the object-lens than on the eye-lens; as the image formed by the former was still so imperfect as not to bear much additional magnification; although achromatic eye-pieces could even then be made with one kind of glass. The great step required for shortening the unwieldy instrument was therefore the perfecting of the object-lens. We have already seen how this was effected. Various very ingenious

improvements on achromatic combinations, even yet (we should be inclined to think) worthy the consideration of opticians, were devised by Dr Blair. He obtained in solutions of mercury or antimony in hydrochloric acid, media, in which, while much more refractive and more dispersive than crown-glass, no irrationality of dispersion as compared with crown-glass could be detected. With these fluid lenses he was enabled to give the telescope an aperture of ⅓d of its focal length without a trace of residual colour. The *dialytic* telescope, invented in 1828 by Mr Rodger, and since made by Plössl, seems to promise very well. Its object is to obtain a large aperture for the telescope with a flint-lens (the obtaining of which, in large and perfect discs, is the great difficulty) of moderate size. In this telescope the object-lens is single, and of crown-glass; having, of course, all the defects of the single lens. These are corrected, at some distance in the cone of converging rays, by the interposition of a combination of a pair of much smaller lenses, whose focal lengths are equal for red rays; the first being a convex lens of crown, the second a concave of flint, glass. The adjustments of this instrument for exact correction are, a motion of the pair of lenses to or from the object-lens, to correct chromatic aberration; and a change of the distance between the two smaller lenses, to correct spherical aberration.

Chromatic being so much more serious than spherical aberration, it is not to be wondered at that the idea of substituting an object-mirror, in which the former is absent, for an object-lens, was early suggested. The first practicable scheme for the purpose seems to have been that of Gregory; in which, however, two mirrors are employed. In the skilful hands of Short, this instrument completely superseded the ordinary astronomical telescope. Its chief defects are, the great loss of light by two direct reflections, and the increase of the spherical aberration by the fact that both mirrors are concave. The first defect is incurable, the second was partially overcome by Cassegrain's plan of using a small *convex* mirror for the second reflection. To Newton is due the simple idea of using the combination of a single curved mirror with a plane mirror and an eye-piece; a construction differing only in slight particulars from that now universally adopted for reflecting instruments. Newton constructed several such telescopes with his own hands, some of which are still preserved, as in the apartments of the Royal Society at Burlington House.

The elder Herschel constructed for himself all the instruments, gradually increasing in magnitude and optical power, by means of which he made his grand discoveries; and his son worthily succeeded him, both as constructor and observer.

The gigantic telescopes of Lord Rosse and Mr Lassell are wonderful examples of delicate art, and have had their full share with the large achromatics of Alvan Clark of Boston in the startling discoveries of modern astronomy.

The process of Liebig for depositing on glass an exceedingly thin film of silver, which, by careful polishing, can be rendered more highly reflective than any other material, has been taken advantage of by Steinheil in the construction of large specula. This is an immense step, since any disc of glass will do, its optical properties not being employed; while, if it be once brought to a true parabolic figure, the silvering may be renewed as often as may be required. One of the great difficulties in the construction and working of large reflectors has hitherto been the casting and annealing of metallic masses of a few tons' weight. This, in the silvered specula, is entirely avoided. We cannot here enter into a description of the processes, often extremely ingenious, which have been devised for the grinding, figuring, and polishing of lenses and specula. The reader who desires strictly scientific information, conveyed in a thoroughly popular form, on this and all other points connected with the subject, is referred to Sir John Herschel's article 'Telescope,' in the *Encyclopædia Britannica.*

TELEURASPIS, a genus of arboreal crotaline serpents, near the Copperheads, from Central America.

TELFORD, Thomas, an eminent engineer, was born in the parish of Westerkirk, in Eskdale, Dumfriesshire, 9th August 1757. His father was a shepherd; and during the intervals of his attendance at school, young T. followed the same occupation, diligently employing his leisure moments in the perusal of whatever books were within his reach. At the age of 14, he adopted the trade of a stone-mason; and long years afterwards, when he had attained the summit of his profession, he confessed the advantages which he derived during this period from 'the necessity of making himself acquainted with every detail in the procuring, preparing, and employing of every kind of material, whether it be the produce of the forest, the quarry, or the forge.' In 1780, he removed to Edinburgh; and in 1783, he repaired to London, obtaining employment under Sir William Chambers, who was then engaged on his chief work, the erection of Somerset House. T.'s merits attracted the notice of his employer, and he was appointed in 1784 to superintend the erection of the resident commissioner's house at Portsmouth dockyard, a work which lasted over three years, and afforded T. the opportunity, of which he fully availed himself, of mastering the details of construction of docks, wharf-walls, &c. In 1787, he was appointed surveyor of public works for Shropshire; and his two bridges over the Severn at Montford (3½ miles west-north-west of Shrewsbury) and Buildwas (1½ miles west of Coalbrook Dale), a large number of minor bridges, and other county works, testified to the genius and industry of the rising engineer, and gained for him the planning and superintendence of the projected Ellesmere Canal, 103 miles in length, to connect the navigation of the Severn, Dee, and Mersey—a work which occupied ten years (1795—1805), and greatly added to the already eminent reputation of Telford. In 1790, he was appointed by the British Fishery Society to inspect the harbours at their various stations; and in 1801 he received a commission from government to report on the state of Scotland, and on the desirable public works for that country. As a consequence, the plan of a canal from Inverness to Fort-William was revived, and its planning and construction intrusted to T. (see Caledonian Canal). In the same capacity of engineer to the parliamentary commission of roads and bridges for Scotland, he executed more than 1000 miles of road in the Highlands, Lanarkshire, and Dumfriesshire (see Road-making), and erected about 1200 bridges, besides churches, manses, harbours, &c. In 1808 and again in 1813, he was invited to Sweden, to report on the projected scheme for connecting Lake Wener with the Baltic, and superintended the construction of the Gotha Canal, by which this was effected, receiving on his departure numerous and valuable marks of the royal approbation. His next great work was the construction of the road from London to Holyhead, including the erection of numerous bridges—among others, of the Menai *Suspension Bridge* (q. v.)—and the last was the execution of the St Katharine's Docks in London, a work of remarkable merit. His other works are far too many to enumerate. We can only afford to state that, of bridges, the Conway (q. v.), the Broomielaw at Glasgow, the Dean in Edinburgh, the Over at Gloucester (an innovation on the ordinary form); of

canals, the Glasgow and Paisley, the Macclesfield, the Birmingham and Liverpool Junction, the Gloucester and Berkeley, the Weaver system, the great tunnel ($1\frac{2}{3}$ miles long) on the Trent and Mersey; of harbours. Peterhead, Banff, Fraserburgh, Fortrose, Cullen, and Kirkwall—were planned by this indefatigable genius, and wholly or partially erected under his superintendence. He was much employed by parliament to report on all public engineering schemes or works of importance, and was also occasionally consulted by the Russian government. For the last few years of his life, he retired from the active duties of his profession, employed himself in collecting and arranging materials for a complete history of his various works, and had the greater portion of the MS. ready when he was seized with a severe bilious attack, and died at Abingdon Street, Westminster, 2d September 1834. His life, entitled *The Life of Thomas Telford, Civil Engineer, written by himself*, was published in 1838, in 1 vol. 4to, accompanied with a companion volume of plates. While a mason in Dumfriesshire, he was known favourably as a writer of short poems, in the homely dialect of his district, which are to be found in the appendix to his autobiography. He completed his imperfect school education during the intervals of business, becoming an excellent linguist, and contributed to the *Edinburgh Encyclopædia*. He was elected a member of the Royal Society of Edinburgh in 1803, and of its more eminent southern sister in 1827.

TELL, a district in the extreme north-west of Africa, stretches along the shores of the Mediterranean, and comprehends the corn-growing tracts extending south from the Mediterranean to the Atlas Mountains, and from west to east through Morocco, Algeria, and Tunis. The T. is noticed under the articles Africa and Sahara (q. v.).

TELL, William, was, according to Swiss tradition, a patriot who, in the 14th c., rescued his native district from the tyranny of the House of Austria. His story has been variously told, but that version which has found the widest currency is the following. In the beginning of the 14th c., Albert I. of Austria was striving to annex the three Waldstädte, Uri, Schwyz, and Unterwalden, to his family estates. Hermann Gessler, his bailiff (or *Landvogt*), lived at the castle of Küssnacht, and perpetrated on the people of the district the most atrocious cruelties. A league was formed of the principal men of the Waldstädte to resist the Austrian pretensions, and to it belonged Walter Fürst, and William Tell, his son-in-law. Among other acts of tyranny, Gessler placed the ducal hat of Austria on the top of a long pole, erected in the market-place of Altorf, and gave orders that no one should pass without uncovering his head. T. and his little boy one day took no notice of the hat, and were at once dragged before Gessler. He, hearing that T. enjoyed great reputation as a cross-bowman, resolved to make his skill a means of punishing him. He was ordered to shoot an apple from his son's head, and told that if he missed it, he should die. To the amazement of all present, he hit the apple without injuring the child. But this did not satisfy Gessler. Turning to T., he asked him what he meant to have done with a second arrow he had in his girdle. 'To have shot you, if it had slain my son,' was the reply. T. was then seized, bound, and thrown into a boat on the Lake of Lucerne, to be taken with Gessler and his men to the castle of Küssnacht. A sudden Alpine storm sprung up. T. was the only man on board who knew the shore, and could manage a boat in such weather. He was allowed to take the helm, and he soon ran her towards a rocky ledge; he there seized his bow and arrows, sprang on shore, and pushed the vessel back into the water. The storm, however, abated, and Gessler and his party landed. T. lay in wait for them in a rocky defile, and as they passed, he shot Gessler through the heart. This befel in 1307, and the great war of the Swiss against Austria followed, which did not terminate till 1499. T., however, is not said to have taken any prominent part in it. He was drowned, it is added, in 1350, in attempting to save a friend during a great flood of the river Schächen.

There is evidence that, in 1387, a religious service was instituted to commemorate the act of T. at the place where he lived; and that, in the following year, Tell's Chapel was built on the spot where the boat was said to have landed. Russ and Etterlin, chroniclers who lived towards the end of the 15th c., told his story as true history. Tschudi, who wrote in the first part of the 16th c., repeated it in the form in which it is now familiar to us, and in which it was adopted by Schiller, in his well-known drama. So early as the end of the 16th c., however, doubts were expressed of its authenticity. Guilmann, who wrote a book, *De Rebus Helveticis*, called in question the very existence of Tell. What, he asks, has become of his family and relatives? Why was he not spoken of by his contemporaries? Grasser, the author of a Swiss *Heldenbuch*, pointed out a striking resemblance between T. and Toke, the hero of an old Scandinavian fable, recorded by Saxo Grammaticus. From that period, incredulity became general, and several books were published to shew that the story was legendary. One of these, *Guillaume Tell; fable danoise*, was burned by the public hangman at Uri, and then a patriotic feeling was manifested on the subject, which, it is believed, made Swiss writers, including J. von Müller the historian, cautious in expressing farther doubt. Voltaire, in speaking of T., makes the remark, that '*ces histoires de pommes sont toujours suspectes*,' and asserts that no part of the tale had a foundation in fact. His opinion became known all over Europe, and since then, a whole library has been published on the story of T., in Switzerland, Germany, Denmark, and France. The most important works, however, bearing on the question, are (1) Ideler's work, *Die Sage vom Schusse des Tell*, published at Berlin in 1826, in which it is shewn that the incident of the apple is purely legendary; (2) an edition of Russ's Chronicle, edited, in 1834, by M. Schneller of Lucerne, in which it is proved that serious disparities exist between the different versions of the story as told by the Swiss chroniclers; and (3) a work containing a series of documents relating to early Swiss history, published in 1835 by M. Kopp, also of Lucerne, in which it is as satisfactorily shewn that, although a continuous series of charters exist relative to the bailiffs of Küssnacht in the 14th c., there is no Gessler among them. T. is nowhere mentioned in contemporary records; but it need not, therefore, be inferred that an obscure peasant did not exist of the name, who shot an Austrian bailiff on the banks of the Lake of Lucerne, who by this act caused a revolt, and who lost his life in attempting to save that of a friend. If such incidents really occurred—and from the early foundation of Tell's Chapel, and other facts connected with it, we must presume they did—it would be easy to explain how they became connected with the old fable of the tyrant, the bowman, and the apple.—Ample information on the Tell controversy will be found in Hisely's *Recherches Critiques sur l'Histoire de Guillaume Tell* (Lausanne, 1843).

TELLEZ, Gabriel, better known by his literary pseudonym of *Tirso de Molina*, a Spanish dramatist

of great reputation, was born at Madrid in 1585, became a monk in 1620, and died in 1648, prior of the order to which he belonged. T. was a friend and pupil of Lope de Vega, whom he almost rivalled in facility of execution. In the preface to his *Cigorrales de Toledo* (1621), a collection of novels and comedies, he reckons the number of the latter composed by him at 300; of which, however, only 68 have come down to us. Besides these, he wrote several Interludes, a great number of *Autos Sacramentales*, an *Acto de Contricion en Verso*, and a *Genealogia de los Condes de Sástago* (Mad. 1640). T. ranks next to Calderon and Lope de Vega as a dramatist. Although he generously affected to consider himself only a follower of the latter, he is really one of the most decisively original geniuses of his country, and imitated Lope in nothing except in cultivating the same national spirit in literature. His plays, deficient in artistic conception, are full of dramatic vitality. The 'situations' are numerous and captivating; the delineation of character fresh, piquant, and vigorous; the wit abundant, and the language richly poetical.—The best edition of T.'s works is that of Don Juan Eugenio Hartzenbusch, in the *Teatro Escogido* (12 vols., Madrid).

TELLICHERRY. See SUPPLEMENT in Vol. X.

TELLING FORTUNES is a criminal offence when accompanied with begging of money or with fraudulent objects. Every person going about pretending or professing to tell fortunes, or using any subtle craft, means, or device, by palmistry or otherwise, to deceive and impose on Her Majesty's subjects, is deemed in law a rogue and vagabond, and may be committed to the house of correction for three months, with hard labour, by a justice of the peace.

TELLI'NIDÆ, a family of lamellibranchiate molluscs; having the mantle widely open in front; the foot tongue-shaped; the siphons separate, long, and slender; the shell usually equivalve and shutting close, the hinge toothed. The species are very numerous, and are found in almost all seas, mostly living in sand or sandy mud, some of them at a considerable depth. The fossil species are also numerous, and are found in the more recent formations. The genus *Donax* belongs to this family.

TELLU'RIUM (symb. *Te*, equiv. 128, spec. grav. 6·183) is one of the chemical elements, which some authorities place among the metals, and others among the non-metallic bodies or metalloids. Although in its outward characters it closely resembles the metals, its close analogies with sulphur and selenium indicate that its true place is amongst the metalloids. It possesses a high metallic lustre, and resembles bismuth in colour; it fuses at about 850°, and at a higher temperature is converted into a yellow vapour; it is a bad conductor of heat and electricity. When strongly heated in the air, it burns with a blue flame, and gives off white fumes of tellurous acid. Like sulphur and selenium, it is soluble in cold oil of vitriol, to which it gives a fine purple-red colour, and on dilution it is precipitated unchanged; and in these respects it differs from all metals. In nitric acid it dissolves with oxidation.

Tellurium forms two compounds with oxygen, viz., *Tellurous oxide* or *anhydride*, TeO_2, and *Telluric oxide*, TeO_3. *Tellurous hydrate* or *Tellurous acid* (H_2TeO_3) exhibits very slight acid properties, and is in the form of a light earthy powder having a bitter metallic taste. Its salts also have a metallic taste, and are said to act powerfully as emetics. *Telluric acid* (H_2TeO_4) has only a feeble affinity for bases. Most of the tellurates are insoluble and are obtained by precipitation. Tellurium unites with hydrogen to form telluretted hydrogen, TeH, which is a gaseous body, analogous to sulphuretted hydrogen, and precipitates most of the metals from their solutions in the form of tellurides, which have a close analogy with the corresponding sulphides.

In experimenting upon the action of the salts of tellurium, it has been found that they possess the power of forming, in the body of a healthy person, compounds which impart to the breath, to the perspiration, and to the gases generated in the intestinal canal, a disgusting fœtor, which makes him a nuisance to every one he approaches; and this smell may last for weeks, although the quantity of tellurium that was administered did not exceed a quarter of a grain.

Tellurium is a rare substance, found chiefly in Transylvania, but recently discovered in Hungary, in North America, and in the Altaï silver mines. It sometimes occurs native, but more commonly as a telluride of gold, lead, or silver. For the method of extracting it, we must refer to any of the larger works on chemistry, and especially to the *Lehrbuch* of Berzelius. It was discovered in 1782 by Müller von Reichenstein, but it was not till 1798 that its properties were accurately studied by Klaproth. The word tellurium is derived from the Latin *tellus*, the earth.

TEMBU (Abatembu, or Tambookie) is the name of an important tribe of Kaffirs, occupying the region east of the present boundary of the Cape Colony, where it forms the eastern limit of the district of Queenstown, formed by Sir Harry Smith in 1849—1850, a rather elevated plateau, from which flow the headwaters of the Kei, Bashee, Tsomo and other important rivers. They number about 90,000 souls, and are of a less warlike and predatory nature than the adjoining tribes of the Amaxosa and Amagaleka Kaffirs. In the earlier Kaffir wars and even in the great one of 1835—1836, the Tambookie Kaffirs remained neutral, and even friendly to the colonists; but in the war of 1848—1849 they were induced to join the other tribes, and were defeated with great loss by a small colonial force. In the war of 1851, they were much broken and scattered; but eventually submitting to the British authority, they have quietly located themselves in the unoccupied country east of the White Kei and Tsomo rivers, a good pastoral region, but rather bare of wood. Wesleyan missionaries have several stations amongst the Tambookie tribe, and many of them exhibit very pleasing features. A British resident, paid by the Cape Colony, also resides amongst them.

TEMESVA'R, the capital of the Temeser Banat (q. v.) or Servian Woiwodschaft, is a strongly fortified city on the Bega Canal, 358 miles south-east of Vienna, by the Vienna and Basiasch Railway. There is an inner fortified town, properly so called, and three suburbs. Though surrounded by marshes, T. has rather a pleasing aspect. It is the residence of the military governor, the seat of a Roman Catholic and a Greek-United bishop, is built with tolerable regularity, and contains many beautiful houses and many excellent educational and other institutions. Tanning and leather-making are considerable branches of industry, and the transit-trade, especially that with Turkey, is important. T. has endured a vast number of sieges—the latest being that of 1849, when it was bombarded for 107 days by the Hungarian insurgents, but was relieved at the end of that time by Marshal Haynau. Pop. (1880) 33,829.

TE'MPÉ, a narrow valley or gorge, about 4½ miles long, in the north-east of Thessaly, between Olympus (q. v.) and Ossa (q. v.), through which flows the river Peneus. The classic poets (none of

whom, curious to say, appear to have ever seen the glen) praise it for its matchless beauty, and hence the name became with them a synonym for any lovely vale. In point of fact, however, the scenery of T. is characterised by wild grandeur rather than by soft sylvan charms.

TE'MPERA, in Painting, the same as *Distemper* (q. v.).

TE'MPERAMENT is a term which has been employed in Physiology ever since the time of Galen, to designate certain physical and mental characteristics presented by different individuals. Dr Todd, in his article on this subject in the *Cyclopædia of Anatomy and Physiology*, observes that 'the temperaments the existence of which seems most consistent with observation, are those admitted by Cullen, namely, the *sanguineous* and the *melancholic*, the *phlegmatic* being a degree or modification of the sanguineous, and the *choleric* of the melancholic.'

Individuals of the *sanguineous* or *sanguine* temperament are such, according to Cullen, as have the quantity of fluids in the body large in proportion to the solids; the habit of body soft and plump; the skin smooth, white, and readily sweating on exercise; the hair soft, and generally pale, passing from thence to a red tint; the complexion ruddy; the eyes blue; the bodily strength moderate; and the mind sensible, irritable, cheerful, and unsteady. In persons of the *melancholic* temperament, the habit of the body is somewhat hard and meagre; the skin and complexion coarse, and of a dun colour; the hair hard, curly, and black; the strength considerable; the mind slow, disposed to gravity, caution, and timidity, but tenacious and steady.

Some writers recognise a *nervous* temperament, in which the predominating characteristic is a great excitability of the nervous system, and an undue predominance of the emotional impulses. This temperament is always associated with the sanguineous or the melancholic. In both sexes, the characteristics of the temperaments are far less manifest in old age than in earlier life. If it be admitted, as Dr Todd believes, that a constant connection exists between colour and temperament, it obviously follows that the nature of the temperament is determined by certain peculiarities in the physical condition of the organism. The different temperaments often merge so gradually into one another that it is in many cases difficult to decide positively to which variety any special case belongs.

TEMPERAMENT, in Music, a system of compromise in keyed instruments for the avoidance of the necessity presupposed by the strict relation of musical intervals of having a separate row of keys corresponding to each tonic. Taking C as keynote, the ratios of the notes of the diatonic scale, as derived from the number of vibrations in a given time of a string sounding that note (see MUSIC), are:

C	D	E	F	G	A	B	C
24	27	30	32	36	40	45	48

The intervals between these notes are by no means equal, and may be thus expressed in numbers by logarithms:

C–D	D–E	E–F	F–G	G–A	A–B	B–C
51	46	28	51	46	51	28

We have here three species of intervals, of which those represented by 51 are called major tones; those by 46, minor tones; and the smaller intervals represented by 28, semitones. These intervals will evidently only serve with C as keynote. If, for example, we start from D instead of C, we find E a tolerable, though not quite correct, second to D; but the third and seventh of the scale are entirely wrong. Were the major and minor tones equal, and each semitone exactly half a tone, the insertion of a note in the middle of each tone dividing the seven intervals would make it immaterial where the scale began; any one of the twelve notes becoming alike available as a keynote; and though such equality is contrary to the immutable principles of harmony, an arrangement based on it is found practically to give but little offence to the ear. In what is called the *equal temperament*, the twelve intervals are all of the same length, and no advantage is given to one key over the rest. This is, in theory at least, the temperament adopted in the pianoforte. Another system, known in this country as *Smith's* or the *vulgar temperament*, in which some keys were favoured at the expense of others, has been much used in organs. While the keys of B♭, F, C, G, D, and A are more perfect than on equally tempered instruments, E♭, A♭, D♭, and F♯ contain some very harsh intervals. The bad fifths and thirds which exist in these keys are designated by musicians by the name of *Wolf* intervals. This mode of tuning the organ is being more and more abandoned for the equal temperament, or an approximation to it. The different characters of the various keys often observed on the pianoforte, as well as the organ, could have no existence were the temperament absolutely equal, and arise out of the circumstance that this strict equality is not altogether adhered to in practice.

TE'MPERANCE. *History of the Movement.*—The origin of the temperance movement dates from the beginning of the present century; and the merit of having taken the first steps in the matter belongs to America, where the vice of drunkenness appears to have reached an alarming height about that time. In the month of April 1808, a society was established at Moreau, county of Saratoga, in the state of New York, consisting of 43 members; one of whose rules was as follows: 'Art. 4. No member shall drink rum, gin, whisky, wine, or any distilled spirits, or compositions of the same, or any of them, except by the advice of a physician, or in case of actual disease (*also excepting at public dinners*), under the penalty of 25 cents, provided that this article shall not infringe on any religious rite.' This society had other rules prohibiting members (under penalties) from offering any of the above liquors, or from being intoxicated; but though it continued to exist for 14 years, it does not seem to have accomplished much good. Gradually, however, the attention of the clergy and of philanthropical laymen was called to the subject; and after a series of sermons had been preached and published against a vice whose rapid progress was threatening (according to Dr B. J. Clarke) to make the Americans 'a community of drunkards,' a society was started at Boston (February 1826), called *The American Temperance Society*, 'to restrain and prevent the intemperate use of intoxicating liquors.' In 1829, *The New York State Temperance Society* was formed; and before the close of the year, 1000 local societies, with 100,000 members, were in existence, and a periodical, entitled *The Journal of Humanity*, established to promote the new movement. Rumours of the progress of temperance societies soon reached the Old World, and in August 1829, a society was started at New Ross, in the county of Wexford, Ireland, under the auspices of the Rev. George Whitmore Carr, the members of which pledged themselves 'to abstain from the use of distilled spirits, except as a medicine in the case of bodily ailment;' and further, 'neither to allow the use of them in their families, nor to provide them for the entertainment of friends.

Simultaneously, a movement in favour of temperance was begun in Belfast and the north of Ireland, by the Rev. Dr Edgar, Rev. Dr Cooke, and Rev. Mr Morgan, and before 12 months were over, 60 societies had been constituted, numbering about 3500 members, both Catholics and Protestants. Meanwhile, Scotland had not been uninfluenced. As early as October 1829, Mr John Dunlop of Greenock, a justice of peace for Renfrewshire, after lecturing on the subject of temperance in Glasgow, Stirling, and elsewhere, succeeded in forming a society at Greenock, the first in Scotland, and the precursor of *The Glasgow and West of Scotland Temperance Society*, formed in the ensuing November. Mr Dunlop is thus entitled to be considered 'the Father of temperance societies in Great Britain.' In his early labours, he was greatly assisted by Mr William Collins of Glasgow, who became the editor and publisher of the *Temperance Record* (1830—1835). The rules of *The Glasgow and West of Scotland Temperance Society* were substantially the same as those of the American and Irish societies—the members voluntarily agreeing 'to relinquish entirely the use of ardent spirits, except for medicinal purposes,' although 'the moderate use of other liquors is not excluded.' The zeal and activity of this society were remarkable. According to the Report read at the first annual meeting (December 30, 1830), it had circulated in the course of the year 125,300 tracts and 20,200 pamphlets, and numbered in Glasgow alone 5072 adherents; while it was stated that throughout Scotland at large there were 130 societies, and 25,478 members. It is not necessary to follow further in detail the course of the temperance movement, *strictly so called*, in Scotland, except to remark, that numbers of the clergy now began to interest themselves in it, and at the close of 1831, there were 187 ministers of various denominations in Scotland connected with the cause; but we must now notice the introduction of a new and more stringent application of the temperance principle. On the 21st September 1830, Mr John Davie, and several other members of the Temperance Society of Dunfermline, pledged themselves to 'total abstinence from all intoxicating liquors—small-beer excepted, and wine on sacramental occasions;' and in the course of the next two years, 'Total Abstinence Societies' were started in Glasgow, Paisley, and other places. In 1830, the temperance movement extended to England. Mr Henry Forbes, a merchant of Bradford in Yorkshire, happening to be in Glasgow on business, had attended one of the meetings of the Glasgow Society, became deeply interested, and on his return home took steps to organise a Bradford Society (February 2, 1830). Another society was formed at Warrington (April 4, 1830); a third at Manchester (May 12, 1830); and by the close of the year, about 30 temperance societies were in existence, numbering in all 10,000 members. In June 1831, *The British and Foreign Temperance Society* was organised in London, mainly through the persevering efforts of Mr William Collins of Glasgow. This was for many years the leading society of the party, its patron being the Bishop of London, and its vice-presidents including several other prelates, distinguished officials both civil and military, and a few members of parliament. The pledge taken by its members was simple: 'We agree to abstain from distilled spirits, except for medicinal purposes, and to discountenance the causes and practice of intemperance.' We have not space to narrate its history and progress in detail, but we may notice that it was instrumental in awakening an interest in the temperance movement both in the army and navy, and that, in the course of a single year (1831—1832), it could boast of having induced 400 old Greenwich pensioners to give up their grog!

Gradually, however, the more fervid friends of temperance in England, arrived at the same conclusion as the Dunfermline 'reformers'—viz., that a crusade against gin and other 'alcoholic' liquors was not enough; that 'beer' was the great cause of drunkenness in their country, and that nothing but total abstinence from all intoxicating drinks would cure the evil. The movement in this direction first took shape at Preston in Lancashire, in September 1832, when Mr Joseph Livesey, and some other members of the Temperance Society there, pledged themselves 'to abstain from all liquors of an intoxicating quality, whether ale, porter, wine, or ardent spirits, except as medicines.' An active propagandism in all the principal towns of Lancashire followed, and a considerable number of adherents were gained to the new cause. In September 1833, according to the commonly received story (see Burne's *Teetotaller's Companion*, p. 333), the notable word *Teetotal* was first used. A certain Richard Turner, or, as he was more generally called, 'Dicky Turner,' a plasterer's labourer or *lime-larry*, who was much given to holding forth in the Lancashire dialect at the meetings of the new sect, happened in the course of a philippic against temperance to say: 'I 'll hev nowt to do wi' this moderation—*botheration*—pledge; I 'll be reet down tee-tee-total for ever and ever.' 'Well done, Dicky!' said Mr Livesey: 'that shall be the name of our new pledge.' This origin of the word, which appears to make it but a stuttering pronunciation of *total*, has, however, been disputed; and it is affirmed that the term is simply a Lancashire phrase for final, thorough, or complete; thus, when a man is discharged merely for want of work, he is said to be *sacked*, but when discharged from inability to work, *teetotally sacked*. Whatever may have been the origin of the term, the new sect was resolved to be 'thorough.' In April 1834, a *Youths' Temperance Society*, on strictly teetotal principles, was formed at Preston, and before a year had passed, it reckoned nearly 1000 members. By dint of zeal, respectable teetotal societies were also established at Manchester (August 1834), Lancaster (November 1834), Colne (December 1834), Isle of Man (December 1835), and numerous other places. Meanwhile (September 1835), a conference of Lancashire and Yorkshire delegates was held at Manchester, and a new general society formed under the title of *The British Association for the Promotion of Temperance on the Principle of Total Abstinence from all Intoxicating Liquors*. This title clearly indicated the ambitious views of the new sect. It wished, and it hoped ere long, to speak in the name of the whole temperance party; and as early as 1836, one of the Yorkshire district societies, that of Wilsden, ventured to memorialise *The British and Foreign Temperance Society* of London on the subject of the total abstinence pledge. The answer that it received shewed that a disruption was not far off. In Scotland and Ireland, the progress of teetotalism, as distinct from temperance, was not at first very marked; but its votaries were resolute, and held vehement discussions, public and private, with the advocates of the rival system, in which they were generally considered victorious by the crowds before whom they disputed. During 1834—1835, teetotalism was struggling hard for recognition in London—the influential leaders of the old Temperance Society being dead against it. At length, however, owing to the persevering efforts of Mr Livesey of Preston and other enthusiasts, the teetotallers got a footing, and, in September 1835, established *The British Teetotal Temperance Society*, which, in August 1836, was merged into *The New British and Foreign Society*

for the Suppression of Intemperance. Teetotalism now in turn began to get the upper hand, and in the course of the next two or three years, the 'moderate' party almost disappeared; the majority of its members doubtless passing over to the ranks of the total abstainers. But these now fell out among themselves. Up to 1839, *The New British and Foreign Society* had two pledges, the long and the short; the former including the 'neither give nor offer' clause; and the latter omitting it. The more rigorous teetotallers made strenuous efforts to get the 'short' pledge abolished, which were as strenuously opposed, and in a very brief period the whole teetotal world was up in wild commotion on the subject. Various meetings of 'delegates' from the different societies in England, Scotland, and Ireland were held in London in May 1839, under the presidency of Earl Stanhope, and scenes of the utmost disorder ensued. The result was a temporary disruption, and the formation of two societies. Still the cause prospered in spite of fierce distractions. Strong provincial associations were formed in Yorkshire, Leicestershire, Lancashire, Norfolk, and Cornwall and Wales, almost always on the 'long pledge' principle. In Scotland, the 'long pledge' took deep root; indeed, after 1837—1838, the 'short pledge' was scarcely ever thought of. But it was in Ireland that the most brilliant successes attended the movement. In 1838, Father Mathew (q. v.) commenced his extraordinary career, and in less than two years, 1,800,000 men and women were enrolled in *Ireland's Great National Total Abstinence Society.*

The subsequent history of the movement must be briefly sketched. In November 1842, the disruption, above mentioned, of *The British and Foreign Temperance Society* was healed, and the two societies which that disruption had called into existence were amalgamated in *The National Temperance Society.* The work of proselytising then went on vigorously. Innumerable tracts were circulated, and all Britain echoed with the noise of infinite speech. Excursions, processions, Exeter Hall demonstrations, incessant tea-parties, &c. were got up with enthusiasm, which speaks volumes for the energy and sincerity of the teetotal agents. But in a less showy though more noble way, the missionaries of the new faith pursued their benevolent work in the lanes and alleys of large cities, the haunts of profligacy and dissipation, where they sought out the homes of drunkards, and tried (not without success) to rescue them from the power of the horrible vice that was dragging them to destruction. Many instances of this success could be cited—of men seemingly lost to society being reclaimed and raised to positions of honourable usefulness. It is, we are assured, a fact, that the majority of temperance hotels, now established in great numbers throughout the country, owe their existence and success to the enterprise of reclaimed men. Action of this sort—whatever one may think of the movement as a whole—is to be spoken of only with reverence. In August 1846, *The World's Temperance Convention* met in London, on which occasion, 302 delegates were present, representing different societies in the United Kingdom and the United States. Since then, the temperance cause has steadily, if not rapidly, progressed. Numerous local societies have been formed. There is scarcely a town or village in the country but has its fraternity of abstainers. Lecturers are constantly at work; pamphlets of various merit are every now and then making their appearance, advocating on social, religious, prudential, or physiological grounds the adoption of the new system; reviews and newspapers have been started for the same purpose; and at present it is estimated that there are not fewer than 3,000,000 total abstainers (inclusive of juveniles) in Great Britain and Ireland, and a much greater number in the United States of America. Of late years, total abstainers have devoted themselves mainly or largely to advocating the necessity or propriety of imperial legislation on the subject of intoxicating liquor (see below).

Pleas and Counter-pleas.—The question of abstinence from intoxicating liquors is capable of being argued on three distinct grounds, *scriptural, physiological,* and *social.* We propose to furnish a brief synopsis of the leading arguments *pro* and *con* under each of these aspects. First, then, the *Scriptural argument.*

The Scriptural argument in favour of abstinence from intoxicating liquor may be briefly stated. The only 'strong drink' mentioned in the Bible is wine It is both praised and blamed. The question raised by teetotallers is: Are the sacred writers referring in both cases to the same kind of wine? This they deny, and endeavour to make good their denial by an appeal to the original Hebrew. On examination, it is found that ten or twelve different designations for wine are used, but the two by far the most frequent are *yayin* and *tîrôsh.* The first of these is the generic term for wine, and therefore (say the advocates of total abstinence), as it *must* embrace fermented liquor, it is the word used when wine is denounced. Thus, it is *yayin* that is 'a mocker' (Prov. xx. 1), that is not to be looked upon (Prov. xxiii. 31, 32), &c. On the other hand, when wine is praised, *tîrôsh* is the word used, and *tîrôsh* (it is asserted) means the wine in clusters, that is, the actual grape itself, or the unfermented juice thereof, then, as now liberally drunk as a beverage by the inhabitants of Syria and elsewhere. The application of this view to the New Testament is obvious. If there was a wine that might be used, as well as a wine that was condemned—which, ask the teetotallers, would Christ and his apostles be most likely to sanction? The wine that 'maketh red the eyes,' that 'biteth like a serpent, and stingeth like an adder,' that 'deceiveth,' that 'maketh drunken' and 'mad,' or the wine that 'maketh glad the heart,' that is 'good,' a 'blessing,' &c.;—in a word, *yayin* in any of its dangerous forms (*sôbe,* from the root to 'soak;' *chemer,* the 'foaming or bubbling;' and *mesec, mezeg, mimsac,* the mixed wines), or the innocent *tîrôsh,* that cheers, but not inebriates? It is conceived that there can be but one answer to this question, and that every candid and reverent Christian must be forced to the conclusion, that the wine which Jesus made at the marriage-feast at Cana of Galilee, and used in his last supper with his disciples, and which Paul advised Timothy to drink for his stomach's sake, was the unfermented, innocuous, and popular *tîrôsh.*

To this it is replied that the distinction made between *yayin* and *tîrôsh* does not exist. Both parties are agreed that the former term is the generic one (corresponding with the Greek *oinos,* the Latin *vinum,* and the English *wine,* with all of which it is believed to be etymologically connected); but it is denied by the scriptural opponents of total abstinence that *yayin* means fermented, and *tîrôsh,* unfermented wines, exclusively. Not to trench upon the chemistry of the question, which, it is affirmed, wholly disproves the possibility of the 'juice of the grape' being kept for any length of time without undergoing a process of fermentation, and thereby acquiring to a certain degree intoxicating properties, it is alleged that the etymology of *tîrôsh* does not favour the teetotal view. According to Gesenius, it is derived from the root *yârash,* 'to get possession of;' that is, of the

brain. Dr Lees, indeed, quotes Bythner as suggesting that it may have been so named because the vine was a 'possession' in the eyes of the Hebrews; but this is extremely improbable, and in the absence of other explanations, that of Gesenius is certainly to be preferred. Again, *tîrôsh* is not exclusively used to denote the 'fruit' (strictly so called) of the vine; the dreaded *yayin* performs the same harmless function—e. g., in Jer. xl. 10, 12, where it is connected with a verb significant of 'gathering,' and in Ps. civ. 14, 15, with another expressive of growth. It is even denied that *tîrôsh* is ordinarily to be so understood, for although, being mostly found in connection with 'corn,' the verb applied to the consumption of that article of food is by *zeugma* made to apply to the 'wine' also, yet in the only passage where the act of consuming *tîrôsh* alone is mentioned (Is. lxii. 8, 9), the verb is *shâthâh*, which invariably signifies the act of drinking. Lastly, it cannot be shewn that *tîrôsh*, when it does mean wine, means innocuous wine. No doubt, *yayin* is the one generally employed when wine is denounced, and *tîrôsh* when it is praised, but this is not uniformly the case, for in Hos. iv. 11, 'whoredom and wine (*yayin*) and new wine (*tîrôsh*) take away the heart,' *tîrôsh* actually forms (as has been remarked) 'the climax' of intoxicating influences. The conclusion, therefore, to be drawn from a consideration of Scripture is, that the distinction insisted on by total abstainers between the two terms—viz., that the one (*yayin*) means fermented, and the other (*tîrôsh*) unfermented wines, is one that cannot be maintained. Both must be held as referring to fermented intoxicating wine; and the praise of *tîrôsh* is simply to be considered a recommendation of the moderate use of ordinary wine, as the condemnation of *yayin* is to be regarded as a solemn prohibition of excess in the same.

The physiological argument in favour of total abstinence necessarily takes various shapes; for it is concerned with physiological questions which are yet, to a great extent, matter of opinion—of speculation and conjecture, not of science. A question arises upon three distinct points: 1st, the effects of alcoholic liquors in quantities sufficient to produce intoxication; 2d, their effects when habitually used in moderate quantities; 3d, the effect of abstaining from them altogether.

Upon the first point, teetotallers usually maintain that insanity, idiocy, almost every form of organic disease, many chronic, not a few acute disorders, are frequent results of habitual intoxication; that the children of drunkards are often idiotic, and have transmitted to them various diseases, which are produced by excessive drinking—which, therefore, tends to the deterioration of the race; that drunkards are always the first victims of epidemics; and that it can be shewn from tables of mortality that drinking has a marked effect in shortening life. It is not disputed that many of these effects can be connected with the habitual use of liquors in excess; but as to some of the most striking of them, it is denied that they are physiological effects of such excess—being not direct results of hard drinking, but due to the bad conditions under which poor people who drink hard usually live. The question between teetotallers and those who differ from them, at this point, however, is only a matter of degree. The latter admit that alcohol, in narcotic or intoxicating quantities, produces only injurious results. In such quantities, it has a deteriorating, a devitalising influence upon the brain and nervous tissue, and habitual excess in its use is attended by a progressive impairment of nervous structure, indicated at length by such results as epilepsy or delirium. See INTOXICATION. But the results of excess differ greatly, it is said, in the case of different persons, so that, not unfrequently, many years of hard drinking do not affect the system of the drinker in a marked degree.

It is upon the second point—the habitual use of alcoholic drinks in moderation—that the opinion of teetotallers seriously conflicts with that of many physiologists. The teetotal argument—leaving out minor points, such as an alleged effect of alcohol in impairing the digestion—may be stated thus: 1. Alcohol can never have been intended by nature for the food of men. It is never produced spontaneously in nature. The vegetable world yields in abundance the principles which form the flesh, and those which keep up the heat of the body, but the healthy plant never produces alcohol. In the body, too, in health, food is never converted into alcohol. And the body does not merely not produce alcohol; it treats it as a foreign element, and gets rid of it as fast as possible. 2. Alcohol in the body, by taking up the oxygen supplied through the lungs, checks the burning of tissue, upon which life and the production of energy, muscular or mental, depend; and similarly it impedes the efforts of the body to get rid of the waste matters which are the products of the burning. It thus lowers vitality, vitiates the blood, and prevents the production of healthy fibre. Toddy or beer taken at bedtime, instead of being favourable to health, has just the same effect, according to Dr Carpenter, with sleeping in a four-post bed with the curtains carefully tucked under the bed-clothes. In either case, that is, there is a diminution of the supply of oxygen required for vital processes, especially for burning the waste of the body. 3. The stimulation produced by alcohol is succeeded by a recoil or reaction; and to produce a certain effect of stimulation, the quantity taken must constantly be increased. From this cause—to say nothing of social influences connected with drinking calculated to produce the same result—moderate drinking tends to pass into excessive drinking, about the evil consequences of which there is no dispute.

The physiological opinion opposed to those arguments is, that while alcohol, like other similar substances, has, in large quantities, a narcotic, a devitalising effect, it has in small quantities a stimulating effect, between which and narcotism there is a difference, not of degree, but of kind. The stimulating effect is precisely the same with that of highly-nutritious and easily digested food; as regards the vital functions, it differs from the effect of ordinary food only in rapidity of production. It does not substitute an abnormal for the normal action of the bodily organs; it restores their natural functions; and it is capable of rectifying either deficient or redundant functional action. The only positive difference of effect between ordinary food and alcoholic stimulation is, that the latter does not, to any great extent, add to the bulk of the body. There is no recoil or reaction after it, except that, as in the case of ordinary food, the effect is exhausted after a time. There is nothing to support the belief in a reaction, except the depression involved in the gradual recovery from the narcotic effect of a large quantity of alcohol; but between the narcotic effect of a large, and the stimulating effect of a small, quantity, there is, as already said, a difference of kind—their connection is merely accidental. And the experience of mankind—the fact that moderate drinking does not usually pass into excessive drinking—sufficiently shews that it is not found necessary to increase the quantity used for stimulation. Since stimulation restores the natural functions, it, of course, is capable of removing the consequences of functions being perverted. Thus, it is maintained that, among other things, it gives relief from pain

and muscular spasms, reduces the circulation when too rapid, produces healthy sleep, and removes general debility, as well as the fatigue of special organs. Whether it, to an important extent, affects the waste of tissue, or keeps waste matters in the blood, is at present undetermined; however this may be, there is no justification for holding that life is to be measured by the aggregation of tissue, or the rapidity of bodily changes. The notion that alcohol checks the burning of tissue by taking up the oxygen received by the lungs, originated when it was believed, upon the authority of Liebig (it was so believed until a few years ago, but the contrary is generally held now), that alcohol was altogether decomposed in the body. If these views are correct, it follows that alcohol, taken cautiously and in small quantities—the quantities varying with the circumstances and with the constitution of the individual—may be used not only with safety but with advantage.

Under the third head, teetotallers, of course, maintain that total abstinence is highly favourable to health. They adduce their personal experience; the mortality statistics of one or two regiments and of ships' crews mainly, or entirely, made up of abstainers; the evidence of arctic voyagers on the one hand, and of travellers in tropical regions on the other, to prove that in every climate health can be maintained, and is most likely to be maintained, when no use is made of alcoholic drinks. On the other side, the fact that men of all races use alcoholic beverages, is held to shew that men, living as men must usually do, find those beverages useful, if not necessary. It is not disputed that many persons live in health without them—that persons having an abundance of wholesome food, not overworked, living in well-constructed houses, and in wholesome air, can usually dispense with them. But when some, or all, of those conditions are wanting—which in towns, at anyrate, happens in all but exceptional cases—it is alleged that a nearer approach to health is made when a moderate use is made of alcohol.

The social arguments in favour of total abstinence, though very weighty and earnestly insisted upon, can be indicated in a few sentences. It is affirmed that the use of alcoholic drinks is at the root of all the misfortunes of the poorest and most numerous class; that it is the chief cause of pauperism, the chief cause of crime, a frequent occasion of immorality; that it lowers the health and shortens the life of the great mass of artisans and labourers, makes their homes wretched, and exposes them and their families to the evils and temptations of chronic destitution. Then, such are the seductive influences of drink and good-fellowship, that moderate drinkers are in danger of becoming drunkards; thus the use of liquors effects the ruin of a considerable percentage of the middle and upper classes. Total abstinence is demanded as a measure of personal precaution, because no one who drinks at all is safe against falling into drunkenness; as a patriotic duty, incumbent upon those who desire the improvement of the poorer classes; as a duty of example which every man owes to his neighbour, and which, involving self-denial, must have a favourable reflex influence upon character. On the other side, it is not denied that drinking is closely connected with, or that it exasperates, the misery undergone by the poor; but it is denied that it is the cause of the misery. It is maintained that drinking must be regarded as an effect of the bad conditions inherited by the poor, and under which they live. Persons born in close alleys, and brought up in foul air, living always from hand to mouth, often upon insufficient or unwholesome food, feel (it is said) a need of stimulants to support vitality; they drink to excess because they are poor, and thriftless, and reckless, and badly supplied with food, and air, and light. Drinking, then, confirms their poverty, and helps poverty to produce pauperism and crime. It is affirmed that the fluctuations of crime (properly so called) do not depend upon the amount of drinking, but—so far as they can be traced to one circumstance—upon variations in wages; that it is destitution, not drunkenness, that contributes most largely to the production of crime. The drunkenness, the crime, the pauperism, it is maintained, cannot be permanently reduced except through a material and moral improvement being effected among the poor. Then it is denied that moderate drinkers, in general, are in any danger of becoming drunkards; it is persons wanting in prudence, and of intemperate constitution, who are exposed to that danger. It is not disputed, that if a man cannot drink without drinking to excess, it is wise in him to abstain from beverages altogether. It is admitted, too, that if a man has within his family or household a person prone to excess in drinking, it may be his duty to exclude liquors from his house altogether. But it is maintained, that the duty which a man owes to his neighbours, in general, is to shew them an example of temperance, and that he does this if he avoids intemperance. The excesses of others no more impose upon a man the duty of total abstinence from beverages which contribute to his health and comfort, and to his social enjoyment, than the great frequency of imprudent marriages, or the existence of a great social evil in the irregular association of the sexes, imposes upon him the duty of celibacy.

Of late years, total abstainers—in unison with others who, though not themselves abstainers, are anxious to promote public sobriety—have exerted themselves to obtain, in one shape or another, a legislative prohibition of the trade in drink. This movement was set on foot in Great Britain in 1853, by an organisation called 'The United Kingdom Alliance,' on account of the success which had crowned the exertions of teetotallers in Maine and many other of the United States of America. In Maine, the liquor-traffic was suppressed in 1846; the law was made more stringent by a provision for confiscating all alcoholic drinks in 1851; and though, in 1856, the existing laws were repealed, and it became lawful to distil spirits, to sell spirits, and to have spirits in possession, drinking-houses continued to be prohibited. The 'Alliance' soon found that there was no possibility of carrying a Maine liquor-law through the British parliament; and they have accordingly confined themselves to asking for a Permissive Bill, enabling the ratepayers of a parish, if a majority of two-thirds of them should think fit, to suppress all public-houses within the parish. Hitherto, they have been unsuccessful. They support the bill upon the merits by a variety of arguments. Alcohol, they say, being a poison, its sale ought to be subject to the same restrictions as that of other poisons. The legislature has admitted the exceptional and dangerous nature of the liquor-trade, by putting it under strict regulation; in consistency, it should suppress it as a trade altogether. They allege that the amount of drinking in a place always varies directly with the number of public-houses; and then that the amount of crime and of pauperism varies directly with the amount of drinking. In 1857, Dr Lees calculated the expense of the use of liquors to this country at 120 millions a year—the cost of the liquor being put at 60 millions, and the remainder of the amount made up by allowing for the crime and pauperism caused by drinking, the loss of time in drinking, and, through disease induced by drinking, the waste

of life consequent upon it and many minor items. This money, it is said, if not spent upon drink, would have a marvellous effect in improving the condition of the poor. It is declared to be reasonable that the inhabitants of a parish should be left to say whether they would tolerate public-houses or not; also that a great majority of the working-classes desire the passing of the bill. On the other side, it is maintained, *in limine*, that the subject-matter of this bill is so very important, and so full of difficulty, that parliament should not delegate its functions in respect of it to the ratepayers; also, that to do so would be to plant, in every parish in the country, the seeds of perpetual strife. Upon the merits, it is said that a prohibitory law could not be carried out—at anyrate in large towns, where the worst evils connected with drinking are found; and that systematic attempts at evasion would be made, which would demoralise the people, and put them in chronic antagonism to the law. Besides the arguments already stated upon this side, it is urged that—excepting the case of poisonous substances—it is no part of the duty of a governing body to say to its people: You shall not spend your money upon this or that; that it is unreasonable, in a fiscal point of view, to speak of the national resources being wasted upon liquors, any more than upon tea or beef, or other substances which perish with the using; and that the power of procuring articles which are desired is what men work for—the great motive of industry. It is also maintained that compulsory abstinence from drink would not produce the same results as voluntary abstinence; that men would seek indemnifications, resorting, it might be, to other and more injurious narcotics than alcohol, and to vices which might be even more injurious than drinking. It is said that abstinence, to be valuable, must be a sign of a moral improvement; and that it is safest we should leave the poor to face the temptations of their situation, trying to fortify them against these temptations by education, by giving them just moral and religious views—at the same time, holding before them the spectacle of temperance and its results in the case of the more comfortable classes.

The following are the leading organisations in Great Britain, that, with various modifications of creed, carry on the temperance agitation. They can claim as directors and advocates men of acknowledged position and ability; and the aggregate sum of money spent annually is very great. The National Temperance League, London (organ, the *Weekly Record*); the United Kingdom Alliance, Manchester, with numerous branches (organ, the *Alliance News*); the Church of England and Ireland Temperance Society, London (organ, the *Church of England Temperance Magazine*); the Scottish Temperance League, Glasgow (organ, the *League Journal*); the National Band of Hope Union, London (organ, *Band of Hope Review*).

TEMPERATURE OF THE BODY IN HEALTH AND DISEASE. It is universally admitted, as a result of the observations of numerous physiologists, amongst whom our own countryman, Dr John Davy, stands pre-eminent, that although the range of temperature varies in different parts of the human body, the normal temperature at completely sheltered parts of the surface amounts to 98°·4, or a few tenths more or less in temperate climates; and that if there is a persistent elevation above 99°·5, or a depression below 97°·3, some form of disease is certainly indicated. (In warm-blooded animals, generally, the temperature is one degree lower at completely sheltered parts of the surface than in the back of the mouth, or other accessible internal parts.)

Some of the circumstances which cause a deviation from the normal temperature are mentioned in the article on ANIMAL HEAT. It may be further noticed, that exposure to cold without exercise, and sustained mental exertion, reduce the temperature, and that the amount of heat is at first reduced after a full meal, although, as stated in the above-named article, it subsequently rises. Moreover, in the tropics, the average temperature is nearly 1° higher than in temperate regions.

When the temperature rises in cases of disease, the following relation to its augmentation and that of the pulse has been established: *an increase of temperature of* 1° *above* 98° *corresponds with an increase of ten beats of the pulse in the minute.* Thus, if the pulse is 60 at 98°, it is 70 at 99°, 80 at 100°, and so on. It is now established beyond all doubt, by the observations of Wunderlich, Virchow, and many other foreign physicians, and by Parkes, Jenner, Aitken, and Ringer in this country, that the preternatural heat which in certain cases can be detected by the thermometer, and may exist to the extent of 4°, 6°, or even 8° above the healthy average, and which varies in amount in different diseases, in different persons, and at different times of the same day, is the essential symptom of fever. Dr Davy, in his *Physiological and Anatomical Researches*, vol. i. p. 206, describes the case of a lunatic soldier, in whom the accidental discovery that his temperature was 6° above the normal standard, led to the detection of tubercular disease of the lungs and intestines. Wunderlich, whose experience embraces at least half-a-million exact thermometric observations, bears unqualified testimony to the value of this mode of investigation in the early detection of disease, and as often furnishing an important guide to treatment. Some of these instances are quoted by Dr Aitken in his *Science and Practice of Medicine*, 3d ed. vol. i. pp. 44—46.

We give in a condensed form a few of the more important of these observations. In *ague*, the temperature of the body begins to rise several hours before the beginning of the paroxysm; and after the disease *seems* to have disappeared, a periodic increase of the temperature may still be detected, and as long as this continues, the patient is not really cured. In *typhoid fever*, the rise of temperature, or its abnormal fall, will indicate what is about to happen three or even four days before any change in the pulse or other sign of mischief has been observed. A sudden fall of temperature has thus denoted intestinal hæmorrhage several days before it appeared in the stools. A fall as low as 93° was noticed by Parkes in a case of this kind. When a person, who yesterday was healthy, exhibits this morning a temperature above 104°, it is almost certain that an attack of ephemeral fever or ague is coming on; and should the temperature rise up to or beyond 106°·3, the case will certainly turn out one of ague or of some other form of malarious fever. If, during the first day of illness, the temperature rises to 106°, it is certain that the patient does not suffer from typhus or typhoid fever; and if the temperature of a patient, who exhibits the general signs of pneumonia, never reaches 101°·7, it is certain that there is no soft infiltration in the lungs. 'In typhoid fever, a temperature which does not exceed on any evening 103°·5, indicates a probably mild course of fever. A temperature of 105° in the evening, or 104° in the morning, shews that the attack is a severe one, and forebodes danger during the third week. On the other hand, a temperature of 101°·7, and below, in the morning, indicates a very mild attack, or the commencement of convalescence. In pneumonia, a temperature of 104° and upwards indicates a severe attack. In

acute rheumatism, a temperature of 104° is always an alarming symptom. In a case of jaundice otherwise mild, an increase of temperature indicates a pernicious turn. In tuberculosis, an increase of temperature shews that the disease is advancing, and that untoward complications are setting in. In short, a fever temperature of 104° to 105° in any disease indicates that its progress is not checked, and that complications may still occur.'—*Op. cit.*, p. 21. We may further observe that, from the observations of Dr Sidney Ringer, a persistent elevation of temperature exists as an invariable precursor of the growth of tubercle in any organ. As a general rule, when the temperature rises continuously to 106°·2, the prognosis is unfavourable; and when it rises to 110°, a fatal issue is almost certain. The diseases in which the highest temperatures have been observed are scarlatina, in which it has been noted at 112°, and tetanus, in which, at the period of death, it was 112°·5, and an hour afterwards was 113°·8. In Dr Aitken's work, the reader will find a series of diagrams illustrating the range of temperature in ague, erysipelas, measles, pneumonia, simple continued fever, scarlatina, small-pox, typhoid and typhus fevers, &c.; together with a full description of the instruments to be used, the method of using them, and practical rules for recording observations.

TEMPERING METALS. A peculiar effect is produced upon some metals by heating them to redness, and then suddenly cooling them. By this means, extreme hardness is obtained, especially in steel, which is so susceptible to this process, called tempering, that almost any degree of hardness and brittleness can be obtained. If, for instance, we make a piece of steel red hot, and then plunge it into cold water, it becomes hard and brittle when cold, and is actually, though slightly, increased in bulk. But if we reheat the metal, and allow it to cool slowly, it again becomes soft and malleable as before. Moreover, if we again reheat it, but not to redness, and cool it suddenly, it is still further softened. If, before reheating, the surface has been polished, a beautiful shade of colour is produced by the heat, which is varied according to the temperature employed; and so exactly is this the case, that the experienced manipulator is entirely guided by the colour produced, instead of by nice regulations of the heat applied. For ordinary operations, the metal is cooled by plunging it in cold water; but oil, mercury, and saline solutions are used for special purposes. An exact series of experiments has proved that the following colours are produced at the temperatures given: Very pale yellowish, by 430° Fahr.; pale straw, 450°; yellow, 470°; brown, 490°; mottled brown, 510°; purple, 530°; bright blue, 550°; blue, 560°; dark blue, 600°.

TE'MPLARS, KNIGHTS, a celebrated religious and military order, founded at Jerusalem in the beginning of the 12th c., by Hugues de Paganes, Geoffroy de St Omer, and seven other French knights, for the protection of the Holy Sepulchre, and of pilgrims resorting thither. Baldwin II., king of Jerusalem, bestowed on this order their first place of residence; and an additional building was acquired from the abbot and canons of the church and convent of the Temple, whence the order obtained the name of the 'Poor Soldiers of the Temple of Solomon,' afterwards abbreviated into Templars. The knights were bound by their rule to hear the holy office every day, or if prevented by their military duties, to say a certain number of paternosters instead; they were to abstain from flesh four days in the week, and from eggs and milk on Fridays. They might have three horses and an esquire each, but were forbidden to hunt or fowl. In the earlier period of their history, the Templars made a great show of poverty, contrasting much with their later condition. After the conquest of Jerusalem by the Saracens, they spread over Europe; their valour became everywhere celebrated; immense donations in money and land were showered on them; and members of the most distinguished families thought themselves honoured by enrolment in the order. In every country where they existed, they had their governor, called the Master of the Temple or of the Militia of the Temple. The Templars had settlements in England from an early period. The first was in London, on the site of Southampton Buildings, Holborn; but from 1185, their principal seat was in Fleet Street, still known as the Temple. The round church which bears their name was dedicated by Heraclius, Patriarch of the Church of the Resurrection in Jerusalem, in 1185, and the chancel was consecrated in 1240.

The Templars were at first all laymen and of noble birth. Pope Alexander III., however, in 1162, authorised the admission of spiritual persons not bound by previous vows, as chaplains to the order, who were not required to adopt the military vows. A third class was afterwards introduced, consisting of laymen not of noble birth, who entered as serving brothers, some of them being attendants on the knights, and others exercising trades in the houses or lands of the order. Eventually, many persons became affiliated members without taking the vows, for the sake of the protection afforded them. As the power and prosperity of the Templars increased, so did their luxury, arrogance, and other vices, which gave the French kings a pretext for endeavouring to suppress them, and lay hold of their possessions. Accusations, many of which were absurd and incredible, were brought against them by two members of their own body. Their principal enemy was Philippe IV. of France, who induced Pope Clement V. to accede to a scheme by which the whole members of the order were seized and imprisoned, their lands confiscated, and many of them tried, convicted, and executed for capital crimes. The English Templars were arrested by command of Edward II.; and a council held in London in 1309 having convicted them of various crimes, most of which were probably imaginary, the king seized their possessions. In 1312, the whole order throughout Europe was suppressed by the Council of Vienne, and its property bestowed on the Knights of St John, to which latter order their English possessions were formally transferred by a statute of Edward II. in 1323.

The habit of the Templars was white, with a red cross of eight points of the Maltese form worn on the left shoulder. Their war-cry was 'Beau séant;' and their banner, which bore the same name, was parted per fess sable and argent. They also displayed above their lances a white banner charged with the cross of the order. Their badges were the *Agnus Dei*, and a representation of two knights mounted on one horse—indicative of the original poverty of the order.—See Addison's *History of the Knights Templars, the Temple Church, and the Temple* (Lond. 1842); A. O. Haye's *Persecution of the Knights Templars* (Edin. 1865).

TE'MPLATE, a mould in wood or metal, shewing the outline or profile of mouldings, and from which the workmen execute the moulding.

TEMPLE (so called because the Knights Templars had one of their branches in that part of London) in its connection with the law of England, is a part of the city of London occupied exclusively by barristers or attorneys, with few exceptions. It is the joint-property of the two Inns

of Court (q. v.), called the Societies of the Inner Temple and Middle Temple, each of which has a right of calling persons to the degree of barrister—a privilege shared by the two other Inns of Court, Gray's Inn (q. v.) and Lincoln's Inn (q. v.). The Temple consists of buildings occupied by barristers, who rent the same from the above two societies, who are the private proprietors, and issue their own regulations as to the management of the property.

TEMPLE, Sir William, an eminent diplomatist and popular writer, was the eldest son of Sir John Temple, Master of the Rolls in Ireland. He was born in London in 1628, studied for two years at Emmanuel College, Cambridge (where he had the celebrated Dr Ralph Cudworth for tutor), and at the age of 19, went abroad on his travels. He acquired the French and Spanish languages, and also cultivated his taste for English composition. He entered on public life in 1661, as member for the county of Carlow, in the Irish parliament. In 1665, he was selected to proceed to Westphalia, on a secret mission to the Bishop of Münster; and on his return, he was created a baronet, and appointed resident at the court of Brussels. He was, as Sir James Mackintosh has remarked, the model of a negotiator, 'uniting politeness and address to honesty;' while, as a domestic politician, 'in an age of extremes, he was attached to liberty, and yet averse from endangering the public peace.' In fact, the chief aim and desire of this accomplished statesman was to enjoy lettered ease and leisure, apart from all exciting public care and responsibility. His most important diplomatic success was the famous treaty of 1668, known as the Triple Alliance, by which England, Holland, and Sweden bound themselves to unite in curbing the ambition of France. This negotiation was accomplished in five days, in conjunction with the great Dutch statesman, De Witt. At the congress of Aix-la-Chapelle, and at the subsequent treaty of Nimeguen, T. was also a negotiator. He was long ambassador at the Hague, and assisted in bringing about the marriage of the Prince of Orange with the Princess Mary. Charles II. in vain endeavoured to prevail upon him to accept the appointment of Secretary of State; but though shunning such arduous duty, he attempted to reform the government, by establishing, with consent of the king, a privy council of thirty persons, by whose deliberations his majesty promised to be guided in all public affairs. As might have been foreseen, so numerous a council, under such a sovereign as Charles, and in times of such fierce rivalry and faction, proved an utter failure. T. then finally abandoned politics, and retired to the country. When the Revolution placed William III. on the throne, T. was again solicited to become Secretary of State; but he again refused. The remaining ten years of his life were mostly spent at his favourite seat of Moor Park, in Surrey, where he carried out his schemes of planting and landscape gardening, and realised his early wish for studious retirement. During this period, he had, as secretary and humble companion, the immortal Jonathan Swift, who regarded his stately self-complacent patron with more fear and distrust than affection, but who ultimately became his literary executor. T. died at Moor Park, in January 1699. His collected works form four volumes (Lond. 1814).

As an author, T. is now known chiefly by his historical *Memoirs* and his *Miscellanea*, the latter being a collection of essays on various subjects—as government, trade, ancient and modern learning, gardening, heroic virtue, and poetry. He has been considered one of the reformers of our style; 'the first writer,' says Johnson, 'who gave cadence to English prose.' His style has quite a modern air, and is smooth, copious, and agreeable. He is too pretentious as respects scholarship and learning, and has no weight as a political writer; but he expatiates very pleasantly on foreign travel and country life, on flowers and fruits, on parterres, terrace-walks, and fountains. His epicurean temperament is happily and characteristically displayed in the last words of his last essay. 'When all is done,' he says, 'human life is at the greatest and best but like a froward child, that must be played with and humoured a little to keep it quiet till it falls asleep, and then the care is over.' This is taking the battle of life very easily, but it is not in such manner that great men or true patriots are formed.

TEMPLEMO'RE, a market-town of the county of Tipperary, province of Munster, Ireland, is supposed to take its name from a commandery of the Knights Templars, and is situated on the right bank of the river Suir, 9 miles north of Thurles. Although without manufactures of any note, T. has some considerable share of inland traffic. It is a station on the Great Southern and Western Railway, 79 miles distant from Dublin. The public buildings, one of which is an extensive barrack, are substantial, but without any noteworthy architectural character. The pop. is about 2500, of whom almost all are Roman Catholics.

TE'MPO (Ital. time), the degree of rapidity with which a piece of music is to be executed. The rhythmical proportions of notes, as indicated by their form, give them only a relative value, and have no reference to the absolute speed with which the composition should be played. Some compositions require, from their character, a quick lively movement; for others, a slower movement is more suitable; and different terms are used to indicate different gradations of movement. Of these, the principal, beginning with the slowest, are: *Largo*, broad; *larghetto*, somewhat broad; *lento*, dragging; *grave*, heavy, solemn; *adagio*, slow; *andantino*, moving a little; *andante*, moving; *allegretto*, somewhat lively; *moderato*, moderately quick; *allegro*, lively; *vivace*, with vivacity; *presto*, rapidly; *prestissimo*, with great rapidity. These terms are not always used with the precision that might be wished, and sometimes apply more to the character than to the absolute speed of performance. They are often modified by other qualifying words, as *allegro con brio*, lively and with briskness; *allegro appassionato*, passionately excited. The *tempo* is indicated with more exactness by a reference to the beat of the Metronome (q. v.). Thus, M.M.♩ = 120, signifies that 120 beats of the metronome, each representing a crotchet, are to fill up the space of a minute; M.M.♪ = 60, that 60 quavers are to be performed in a minute.

While the general rule is, that the time of a movement is to be steady and unvarying, cases often occur where a certain part of a composition has to be taken quicker or slower than the rest; this is indicated by such terms as *più vivo*, more lively; or *ritenuto*, kept back; while a return to the original time is expressed by the words *a tempo*. The performer may be required to proceed from one degree of movement to another, not abruptly, but gradually; the terms used to express this are: *rilasciando*, slackening; *ritardando*, retarding; *calando*, calming down; *stringendo* pressing on; *accelerando*, gradually increasing speed; with some others.

Tempo Rubato (stolen time) is the name given to a mode of performance in which a restless character is imparted by protracting one note beyond its proper duration, and curtailing another, so that the

aggregate duration of each measure remains unchanged.

TEMPORAL POWER (OF THE POPE) is a phrase susceptible of two meanings, which are very distinct from each other, and the confusion of which has led to frequent and serious misunderstanding.

I. In one of these senses, it means the sovereign power which the pope possessed as ruler of the so-called PAPAL STATES (q. v.), and which was abolished in 1870 by their annexation to the kingdom of Italy. The power which the pope exercised within these states, although modified in its exercise by his spiritual character, was in substance the same as that of any arbitrary sovereign. The history of its origin and progress, and of the variation of the limits within which it has been acknowledged, is briefly detailed under the head PAPAL STATES. The question as to the necessity or utility of such a power vested in the hands of a spiritual ruler, and even of its lawfulness and its compatibility with his spiritual duties, has been very warmly debated. The controversy is not of entirely recent origin. Many of the medieval sectaries put forward the principle of the incompatibility of the spiritual with the temporal power in the same person, not only in relation to the pope, but also as to the baron-bishops or other ecclesiastical seigneurs of that age. Such were the doctrines of the Vaudois, of Pierre de Bruis, and above all, of Arnold of Brescia. The last-named of these rendered himself specially obnoxious by the activity and even turbulence with which he propagated this view, and the sentence of death under which he suffered was the penalty of rebellion quite as much as of heresy. Through the centuries which followed, the anti-papal controversies turned so entirely upon doctrine, that there was little room for the discussion of this question, and it is a mistake to suppose, as has not unfrequently been done, that it entered in any way into the conflict of Gallican and Ultramontane principles. Even the great Gallican champion, Bossuet, not only admitted the lawfulness of the pope's temporal sovereignty, but contended that it was in some sense necessary to the free exercise of his spiritual power, and to the independence of his ecclesiastical government. It was not until the aggression of the French Republic upon Rome, and the subsequent annexation to the Cisalpine Republic, and afterwards to the kingdom of Italy, by Bonaparte, of the three Legations, that the controversy assumed any practical interest. During the later conflict between Pius VII. and the Emperor Napoleon I., the design which the latter entertained of a still further annexation was one of the main causes of dispute; and still more recently, upon the re-annexation of nearly the same portions of the papal territory to the kingdom of Italy, the question violently agitated the entire Catholic world. No formal and authoritative judgment of the Roman Church has been pronounced regarding it; but a strong and almost unanimous expression of opinion was tendered to the present pope, Pius IX., in the form of letters and addresses from bishops and others in every part of Catholic Christendom. The tenor of all these was nearly the same. They professed that the possession of temporal sovereignty is no essential part of the privileges of the successor of St Peter; but they also regarded the possession of a sovereignty independent of any particular sovereign, as the means providentially established for the protection of the spiritual independence of the pope, and of the free exercise of his functions as spiritual ruler of the church. The expression of a contrary opinion by some distinguished members of the Roman Church, although it was understood to be regarded with great disfavour and suspicion, was not formally condemned by a doctrinal decision; but as the actual aggression upon the rights of the Roman see was deemed a violation of the laws of the church, those who were active participators in the aggression were held to have incurred the ecclesiastical censures attached to such violation of the laws.

II. By the second signification of the phrase 'Temporal Power of the Pope' is understood what would more properly be called the claim of the pope, in virtue of his office, to a power over the temporalities of other kings and states.

This power may be of two kinds, *directive* an *coercive*. In the first sense, it is a claim which nc Catholic, consistently with his belief of the spiritual supremacy of the pontiff, can be supposed to deny, as it imports nothing more than that the pope, as supreme moral teacher, has power to instruct all members of his church, whether subjects or sovereigns, in the moral duties of their several states.

If the power be regarded as coercive, it is necessary carefully to distinguish the nature of the coercion employed. That coercion may be exercised either by the threat or infliction of *purely spiritual censures;* or it may involve temporal consequences, such as suspension or deprivation of office, forfeiture of the allegiance of subjects, and even liability to the punishment of death. Considered in the former sense, the claim must be regarded as a natural consequence of the spiritual headship of the church, which is acknowledged by all Catholics; nor can it be denied that the power to compel sovereigns, by purely spiritual censure, to the fulfilment of the moral duties which their state imposes, is a natural concomitant of the spiritual primacy.

But the claim of the popes to authority over the temporalities has gone far beyond these limits. From the 10th c. downwards, they have claimed and have repeatedly exercised a power of coercing, and when refractory, of punishing kings by suspension, by deprivation, and by the transfer of the allegiance of their subjects to another sovereign. This well-known claim has been a subject of controversy in the Roman Catholic Church between the Gallican (q. v.) and Ultramontane (q. v.) schools; and in the Ultramontane school, two different theories have been devised for its explanation. The first and most extreme (which holds the power to be a direct one) supposes that this power was given directly by God to St Peter and his successors, that the two powers are foreshewn by the 'two swords' mentioned in Luke xxii. 38, and that the temporal power is a privilege of the primacy by divine law, equally with the spiritual sovereignty itself. According to the second, or *indirect* theory, the temporal power is not directly of divine institution, but is an indirect though necessary consequence of the spiritual supremacy; and is only given as a means of completing, and, in a corrupt and disorganised state, rendering more efficacious the work which the spiritual supremacy is directly instituted to accomplish. It was in this latter form that the theory of the temporal power was defended by the great champion of Ultramontanism, Cardinal Bellarmine, and the celebrated declaration of the Gallican clergy in 1682 (see GALLICAN CHURCH) was directed against it.

A third view of the temporal power, and one which has found many modern defenders, was propounded by the celebrated Fenelon (q. v.). According to the theory of Fenelon, which is generally described as the historical theory, the pope does not possess, whether by direct divine appointment, or in virtue of the necessities of his spiritual office, any temporal power whatsoever. But he possesses the plenitude of that spiritual power which is required

for the government of the church, and he is empowered to enforce it by spiritual penalties, and especially by excommunication or deprivation of membership of the church. Now, although excommunication and such other penalties, of their own nature, are purely spiritual, yet the religious sentiment of the medieval period, and the profound awe with which it regarded the authority of the church, invested these penalties with certain temporal effects, the chief of which were the forfeiture of civil rights, and the loss of the most important privileges of citizenship, of which well-known examples survived, even in the post-Reformation legislation of England and other Protestant kingdoms. See EXCOMMUNICATION. The penalty of forfeiture of certain civil rights, which, in the case of private persons, the law of England attached to the spiritual censure of excommunication, was applied by the laws of other countries to the sovereigns themselves; by the law of Spain in the sixth council of Toledo in 638; that of France, as confessed by Charles the Bald in 859; the law of England, under Edward the Confessor, and the so-called Saxon and Swabian codes of Germany. The last-named codes recognise in the pope, in certain specified cases, the right to excommunicate the Emperor himself; and ordain that in case the Emperor should remain for twelve months without being absolved from the excommunication, he shall be deposed. In the appeal of the Saxon nobles to the pope against Henry IV., this law is expressly referred to. The contemporary historians, Paul of Bernried, Lambert of Aschaffenburg, Nicholas Roselli, and others, describe it as the ground of the Emperor's deposition; and even Henry himself, without denying the force of the law, sought his defence solely in a denial of the charge of heresy which was imputed to him. The same spirit of the age is exhibited in the form of oath taken at the coronation of the sovereign in many countries, especially (although not exclusively) in those whose kings—as Roger of Sicily, Peter III. of Aragon, Guiscard of Naples, Godfrey of Jerusalem, and John of England—had made their kingdoms feudatory to the see of Rome; by which the monarch swore to be the protector and defender of the sovereign pontiff and the Holy Roman Church in all their necessities and utilities, and to guard and maintain their possessions, honours, and rights.

From these and similar indications of the public feeling of the medieval time, the advocates of this theory of the Temporal Power infer that orthodoxy and obedience to the pope, in all essential matters of faith and discipline, were by the consent, express or tacit, of sovereigns and of peoples accepted as a condition of the tenure of supreme civil authority —a condition similar in its character and objects to that which forms the basis of the limitation settlement of the succession to the English crown, to the heirs of the Princess Sophia of Hanover, 'being Protestant.' Hence they conclude that the function really exercised by the popes in relation to heterodox or scandalously immoral sovereigns, or oppressors of the church and church liberties, was in itself a spiritual one, and that the civil consequences which it entailed of deprivation or deposition arose, not from the church law, but from the expressed or understood international civil law of the age. This view, it should be said, is not confined to Catholic writers, but is held by Leibnitz, Pfeffel, Eichhorn, Voigt, Frederick Hurter (while still a Protestant), and others.

On the other hand, it is difficult, if not impossible, to reconcile this theory with the language used by the popes themselves in enforcing their claim to temporal authority, and with the arguments upon which they rest that claim. Nor can it be denied that, whatever is said of the cases of the exercise of such a power which occurred in the 12th and 13th centuries, the power continued to be claimed and to be exercised down to and even after the Reformation, when it would be idle to suppose that any such public understanding, if it had existed in the middle ages, had not been revoked, if not by all, at least by those nations which had revolted from the Roman Church.

The history of most of the principal instances of the exercise of this power by the popes will be found detailed under the separate articles which refer to the particular popes or sovereigns who engaged in the contest of church and state.—See Gosselin's *Pouvoir du Pape au Moyen-Age.*

TENA'CITY (Lat. *tenacitas*, power of holding) is that property of material bodies by which their parts resist a force employed to attempt to separate them. It is the result of the attractive forces exerted by the particles of matter upon one another through the infinitesimally small spaces which are supposed to exist between them; hence it differs in different materials, and even in the same material at different degrees of temperature. The practical bearings of the tenacity of solids (especially of wood and iron) are discussed in the article STRENGTH OF MATERIALS; and we shall therefore here only state a few of the conclusions at which Muschenbroek and other experimentalists have arrived regarding the modifications which the tenacity of metals undergoes in consequence of various processes. Forging and wire-drawing increase the tenacity of metals in the longitudinal direction. Copper and iron have this property more than doubled, while gold and silver have it more than trebled by these metals being drawn into wire. Mixed metals have usually a greater tenacity than simple ones. See ALLOY.

TENAILLE, in Fortification (q. v.), a work in low relief, constructed immediately in front of the curtain. It may either have two faces, in a line with the faces of the adjoining bastions, and meeting at the centre in a re-entering angle; or three faces, of which two are prolongations of the bastion faces, and one parallel to the curtain. The tenaille must be low enough for the defenders to be safe from the musketry-fire on one bastion defending a breach in the other bastion. This work is of great use in protecting the ditch, covering the postern from the enemy's view, &c.

TE'NANCY AT WILL, in point of Law, means an occupation by a person in the character of a tenant, but for no fixed term other than the will or caprice of the landlord or proprietor. Rent is payable, under a tenancy at will, according to the time of occupation, and the tenancy can be determined by either party at any time. As soon as a tenant at will once pays rent he becomes a tenant from year to year. His tenancy cannot then be determined at the end of the current year, unless a reasonable notice to quit is served by the party intending to dissolve the tenancy of the other. But the tenant is not to be prejudiced by the sudden determination of the tenancy, so that if he has sown the lands, he is entitled afterwards to re-enter the lands, to reap the crops.

TENANCY IN COMMON, in point of Law, means a right to hold or occupy lands, or possess chattels, along with another or other persons. In such a case, each has an equal interest; but in the event of the death of either, his share does not go to the survivors, as is the case in Joint Tenancy (q. v.), but to his heirs or executors. Tenancy in common applies to ownership as well as household interests. Though each tenant has as much right to the whole property as the others, yet neither has a

definite share set apart to himself exclusively. If one wastes or deals with the property to a greater extent than his share, the others can bring an action against him. Each can at any time compel a severance of the property, so that thereafter he may have his own share severally.

TENANCY ON SUFFERANCE differs from a tenancy at will in this, that a tenant at will enters on a good title, whereas a tenant on sufferance has no title, and wrongfully continues. Thus, when the term has ended, and the tenant has got notice to quit, but does not, he continues a tenant on sufferance, and may be ejected at any time, unless the landlord elect to treat him as a tenant in continuation of the former lease.

TENANT FOR LIFE, in English Law, means one who has not the absolute property, but an interest in the property, which ceases with his own life, or the life of another. An estate for life in lands is classed with freehold estates. Where the estate for life depends on the life of a third person, as it is the interest of the tenant that such third person should live as long as possible, frauds are often committed on the reversioner by misrepresenting the fact of such person being alive; hence, to prevent fraud, the reversioner may insist on the third person being produced, failing which he will be taken to be dead. An estate for life is usually created by deed, but there are two legal estates for life—namely, the widow's estate in dower, and the husband's estate by courtesy on his wife's death. As a general rule, a tenant for life of real estate is entitled to take wood to repair and burn in the mansion of the estate; but he cannot for other purposes fell the trees, nor open mines or pits, though, if these have been already opened, he may carry them on. Sometimes a tenant for life is declared by the deed or will to be tenant without impeachment of waste, in which case he can exercise most of the rights of an absolute owner, except cutting down ornamental timber, or defacing the family mansion. Tenants for life may now apply to the Court of Chancery for leave to raise money to drain the lands and make improvements. When a tenant for life dies between the usual terms for drawing rent, the rent is apportioned between his executors and the party next entitled. A tenant for life is called, in the law of Scotland, a Liferenter (q. v.).

TENANT IN FEE SIMPLE, in English Law, is the old feudal description of one who is absolute owner, the fiction being that all were originally tenants of the crown. A tenant in fee simple has a freehold estate of inheritance, which is the highest degree of property known to the law. There is practically no feudal connection with the crown, and he can alienate or devise the property without the leave or sanction of the crown. A tenant in fee simple has an absolute right to the soil and the mines down to the centre of the earth, and has a right to build as high as he pleases. If he dies, the estate goes to his heirs—i. e., his heirs general; but he has power to devise it to whom he pleases, subject to certain restrictions, in cases where the donee is a charitable corporation or trustee for charitable purposes. See MORTMAIN. A tenant in fee simple is called, in the law of Scotland, a Fiar (q. v.).

TENANT IN TAIL. See TAIL, ESTATE.

TENANT-RIGHT. This term is used by the Irish tenantry to denote various claims of right which they maintain against their landlords, such as the right of occupancy not subject to removal; and the right to occupy at a rent not subject to increase on the ground of improvements; it being, they say, inequitable to make them pay rent for what they have themselves produced. The chief claim of right is with respect to the improvements. In Ulster, and in the north of Ireland generally, the equity of this branch of the claim is recognised and acted upon; and the landlord, when the tenant removes, either buys the improvements, or they are bought by the incoming tenant. This recognition of tenant-right in the north of Ireland is traceable to the footing on which the newly settled proprietors in the time of Cromwell arranged with the agriculturists whom they induced to come to them from Scotland. In the south of Ireland, on the other hand, this claim of right has never been conceded by the proprietors; while the right of occupancy not subject to removal has, *de facto*, been enjoyed by the tenants, who, however, are clamouring to have it recognised by law. The non-settlement of the question has long been the cause of bitter controversy, and undoubtedly its existing condition is the root of much of the national misery. Owing to the old tenure of land as tribal or clan property, the people of the south of Ireland have never taken into their minds the notion of 'contracting' with any one as the 'owner' of land. They have the traditional feeling of being themselves the owners; and so much has this feeling been a source of agrarian disturbances, that few Irish 'landed proprietors' have ever ventured fully to exercise their rights of property. And nothing is more common in the south than to find that the land has been in the occupancy of the same families from time immemorial, without lease or contract of any kind. The Irish claim of tenant-right very much resembles that made by the Indian ryots against their zemindars. In India, as in Ireland, until what may be called recent times, land belonged to families or communities, which held themselves to be composed of kindred; but by acts passed by our government, a class of mere tax-collectors have been converted into land-owners, in order to facilitate the collection of the revenue. Hence, there has arisen in India an agitation very much resembling that which prevails in the south of Ireland. The ryot claim of tenant-right was recently the subject of a suit before the supreme courts of India, when a majority of the judges favoured the equitable claim of the ryots. In countries where the people have been trained in notions derived from the Roman or feudal laws, there has been little heard of this species of claim of right, and land has been recognised by the people as being, like other things, a fair subject for contract.

In Scotland and in the north of England, farms are almost always let on long leases, and at such rents as are supposed to repay the tenant the capital which he may lay out in improvements; and the common case is, that the landlord binds himself to pay the tenant a stipulated sum as the value of his improvements, provided that these are found at the end of the lease to be of a certain stipulated value. Over England generally, on the other hand, tenancy can be ended by six months' notice on either side, and the evils incidental to this precarious tenure have been obviated or mitigated solely by the honourable conduct of the English proprietors. It is quite common in England to find that the son has succeeded the father as tenant at will for many generations, often for centuries.

With regard to Ireland, it is quite plain that in a country where two-thirds of the population is agricultural, any hindrance to agricultural trade must be felt with especial severity. Land must be indebted for its improvement either to the capital of the tenant or of the landlord. Now, according to Adam Smith, 'it seldom happens that a great

proprietor is a great improver. . . . To improve land with profit, like all other commercial projects, requires an exact attention to small savings and to small gains, of which a man born to great fortune, though naturally frugal, is seldom capable.' It must be chiefly, then, to the moral quality of the tenantry, and to the inducement held out to them by the state of the law, that a country has to look for the improvement of its land. It must follow, therefore, that the law by which the ownership of improvement follows the ownership of land, is in the present condition of things in the highest degree unjust and inexpedient. The tenant's interest in all his improvements ending with his tenancy, he is very unlikely, at least towards the end of his term, to spend anything on the land which will be of benefit to it; and where he is a tenant at will, he is entirely without interest to improve it.—See *Impediments to the Prosperity of Ireland*, by W. Neilson Hancock (Lond. 1850); also by the same author, *Causes of the Prosperity of the Lothians of Scotland* (Belfast, 1852).

TENA'SSERIM is (together with the province of Martaban) the third or southernmost division of British Burmah*—the other two divisions comprising the ancient kingdom of Pegu and Arracan. On the 31st January 1862, these three maritime provinces were united under one local administration, bearing the name of British Burmah.

T. is a narrow line of coast about 500 miles in length, with a varying breadth of from 40 miles at its southern extremity to 80 miles; the latter distance being measured from the sea-shore at the mouth of the Salween to the range of mountains on the east that separates T. from Siam. It extends from the point of junction of the Thoung-yeen River with the Salween to the Pak-chan River, in 10° 15′ S. lat., and from 97° 30′ to 99° 36′ E. long., with an area of 24,838 square miles.

The division of Tenasserim is divided into five provinces—viz., Toungoo, Schwe-gyen, Maulmain, or Amherst province, the chief civil and military station, Tavoy, and Mergui—which lie along the coast from north to south in the order in which they are here mentioned.

Physical Features.—The general aspect of the country is bold and picturesque. The numerous wooded ranges of hills take generally a course from north to south. The northern part of the country is the most level; the southern portion is little else than a wilderness of thickly-wooded hills, enclosing long and narrow valleys. The soil of the plains is very fertile, and suited to the growth of rice, indigo, cotton, sugar, and vegetables. Tobacco grows chiefly on the banks of rivers in the hills. Only about $\frac{1}{18}$th of the country is under cultivation, and the forests occupy two-thirds of the entire area. The chief rivers are the Salween, Gyne, Attaran, Yé, Tavoy, and Tenasserim. The Tenasserim, from which the country derives its name, is the most considerable river of the province. The principal ports of T. are Maulmain (q. v.), Amherst, Tavoy, and Mergui, of which Maulmain is the best. Amherst harbour, at the mouth of the Salween, affords good anchorage for ships of any draught of water, but is difficult of approach. The Mergui Archipelago, lying off the southern coast of T., consists of almost innumerable islets, some of which are said to be rich in iron ore; and they are famous for their edible birds' nests. Numerous anchorages are found amongst the islands. The country possesses vast stores of mineral wealth, which now lie absolutely neglected. Gold-washing has been pursued with success at the head of the Tavoy River. At Kahan, on Mergui Island, are rich and accessible tin-mines; and thousands of tons of good clean ore, yielding 75 per cent. of the pure metal, could be raised not far from the surface of the ground. A very productive iron ore is obtained from Iron Island, between Tavoy and Tiger Island. Mergui province furnishes a valuable lead ore, and has extensive fields of coal. Manganese has been found on the Tenasserim River, where it is believed to be very plentiful.

Botany.—The botanical productions of T. may vie with those of any part of the world. There are more than one hundred different kinds of timber-trees, of which the teak is the most important. The celebrated *Amherstia nobilis* is the most splendid of the many flowering and ornamental trees for which T. is famous. The palm tribe are in great variety, and Dr Griffith collected 1700 different species of plants in about 14 months.

The *climate* of T. is regulated by the monsoons; and the wet and dry seasons divide the year into two nearly equal parts. The average yearly fall of rain is about 194·28 inches, and this descends during the six rainy months from May to October. The greatest amount of rain ever recorded as having fallen in one day (27th May 1857) is 12·75 inches; and the gauge for the week registered 40·27 inches (Dr Walter). While the rains last, the temperature is very uniform, the thermometer ranging between 76° and 82°. The cool season lasts from the cessation of the rains in October, when the north-east monsoon begins, to the middle of February. During that time, the thermometer seldom reaches 90° in the shade, and occasionally falls as low as 56°, and now occurs the greatest thermometric range, which is sometimes as much as 30° in one day. The sun then gradually regains its power, and the heat increases daily till the south-west monsoon again brings clouds and rain. In the hot period, the thermometer at mid-day is not often below 92° in the shade, and not unfrequently stands at 95°.

Commerce.—The principal exports from T. are teak timber and rice. The trade of the province is, however, not on the increase, but, as it appears, rather the reverse. The first of these articles of export is not continuous from year to year; and we accordingly find that the decrease in the value of trade is owing to the diminished demand for teak timber. Indeed, the defective continuity of supply is to some extent a fact also as regards timber. Rice is the most reliable article of commerce.

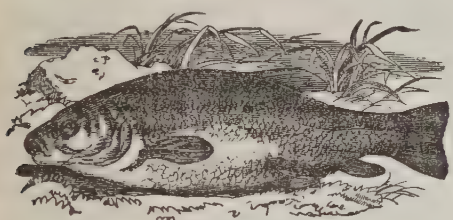
Inhabitants.—By the returns of 1872, the number of inhabitants of the five T. provinces is given as follows: Toungoo, 78,430; Schwe-gyen, 144,919; Amherst, 235,738; Tavoy, 71,494; Mergui, 46,184; total, 576,765. The bulk of these are Burmans proper; but there are, besides, many races and tribes—viz., Talaings, or descendants of the ancient Peguans; Karens, a dispersed people, inhabiting secluded mountain districts—among whom Christianity has made some progress, through the labours of American missionaries; Toungthoos, Khyengs, Shans, Europeans and their descendants, Chinese, and Indians. Throughout T. and British Burmah generally, inheritance and marriage are regulated by Buddhist law, while at the seaports the English mercantile law and law of contracts are in force, and regulate the decisions of the courts.—*The Natural Productions of Burmah and the Tenasserim Provinces*, by the Rev. F. Mason

* The provinces of British Burmah extend along the eastern shore of the Bay of Bengal from the Naf Estuary, in about 20° 50′ N. lat., to the Pak-chan River, in about 10° 15′, with a coast-line of 900 English miles. Their area and population, according to the returns of 1872, are as follows: Arracan, area, 18,530 sq. m., pop. 461,136; Pegu, area, 28,404 sq. m., pop. 1,524,422; Martaban and T., area, 36,750 sq. m., pop. 576,765.

A.M. (Maulmain, 1850); *Six Months in British Burmah*, by Christ. T. Winter (Lond. 1858); *The Tenasserim and Martaban Directory* (Maulmain, 1857); *Reports of the Administration of the Province of British Burmah, for* 1861, 1862, *and* 1863, by Lieut.-colonel A. P. Phayre, C.B., Chief Commissioner and agent to the Governor-general (Rangoon, 1862, 1863). Personal observation.

TE'NBY, a small parliamentary and municipal borough, and thriving watering-place, of South Wales, in the county of Pembroke, and 10 miles east of the town of that name. Its charming situation on a peninsula, overlooking the Bay of Caermarthen, its salubrity of climate, and the facilities for bathing which the extensive sands in the vicinity afford, have made it one of the best and most fashionable watering-places in Wales. A considerable part of the ancient embattled walls of the town still remains. There are also a handsome church and picturesque ruins of a castle. The season lasts from June till October, and the number of permanent winter residents is annually increasing. Fishing is extensively carried on. Pop. about 5000; but during the season the number is greatly increased.

TENCH (*Tinca*), a genus of fishes of the family *Cyprinidæ*, of a thick form, with small scales, and a barbel at each side of the mouth, the teeth on the pharynx compressed and club-shaped. The COMMON T. (*T. vulgaris*) is an inhabitant of ponds



Tench (*Tinca vulgaris*).

and other stagnant waters in Europe and the north of Asia. It passes the winter in a torpid state, concealed in the mud. It is of a deep yellowish-brown colour, more rarely golden or greenish. Instances have occurred of its attaining a length of three feet, but a T. of half that length is unusually large. It is very tenacious of life, and, like the carp, can be conveyed to a distance alive in wet moss. It spawns in May and June, depositing its spawn among aquatic plants. The ova are very small and very numerous. The flesh of the T. is soft and insipid, except when it is very well fed, when it becomes delicate and pleasant. It is commonly placed in ponds along with carp; a much smaller number of T. than of carp, however, being deemed sufficient to stock a pond. In Britain, the T. is found only in England, and there sparingly in some of the slow and muddy rivers. It is not improbable that it may have been originally introduced as a pond-fish, although it has long been naturalised. Angling for T. resembles angling for carp. The same kinds of bait are used.

TE'NDA, COL DE, a pass over the Maritime Alps. See ALPS.

TENDER, as a Legal term, means the formal offer to perform some obligation incumbent on the person tendering. It is more frequently used in reference to the payment of money which is due. Whenever a tender of the debt is properly made, the legal consequence is this, that if the money is refused the creditor will have to pay the costs of any action he may bring to recover it, and cannot claim interest afterwards. In case such an action is brought, the debtor has nothing to do but to plead that he duly tendered the money, and if he then pay into court the sum which he had formerly tendered, the other party must stop the action, or continue it at his own risk. In order, however, that a tender should have the above effect, it must have been duly made—that is to say, it must have been made without imposing any conditions on the creditor, and at the proper time and place. The tender must be in money, and not by bill of exchange; but Bank of England notes are good tender for all sums above £5. If the debt is beyond 40*s.*, it ought to be in gold, so far as it goes. Though other bank-notes than Bank of England notes are often tendered, the creditor is not bound to accept them; but if he take them without any specific objection, then it will be a sufficient discharge. A tender of a larger sum than is due is good, but must not require change to be given, which the creditor is not obliged to find. Nor must any condition be annexed to the tender, not even the condition of giving a stamped receipt, though on other grounds, by statute, a person receiving payment is bound to fill up a stamped receipt on its being tendered to him, and to pay the stamp; and his refusal to fill up the receipt subjects him to a penalty of £10. A tender of payment must, in general, be made to the creditor at the place he has indicated, and it is the duty of the debtor to find out and pay the creditor. With regard to payment of rent, however, it is enough that the tenant be ready to pay the rent on the premises at the time it is due, it being the landlord's duty to send or call for it, for the land is the proper debtor, and that is the place to apply to in the first instance.

TENDER, in Naval language, a small vessel appointed for the service of a larger one. Steam gunboats are most commonly employed as tenders.

TEN'DON is the term employed in Anatomy to designate the white fibrous tissue reaching from the end of a muscle to bone or some other structure which is to serve as a fixed attachment for it, or which it is intended to move. In accordance with their form, tendons have been divided into the three following varieties: (1) *Funicular*, or rope-like, as the long tendon of the biceps muscle of the arm; (2) *Fascicular*, as the short tendon of that muscle, and as the great majority of tendons generally; and (3) *Aponeurotic* or tendinous expansions, sometimes of considerable extent, and serviceable in strengthening the walls of cavities, as, for example, the tendons of the abdominal muscles.

The tendons commence by separate fascicles from the end of each muscular fibre, and they similarly terminate by separate fascicles in distinct depressions in the bones, besides being closely incorporated with the periosteum. In some birds, whose tendons are black, the periosteum is black also, from this incorporation. If a tendon is ruptured by an accident, or divided by the surgeon, the two ends, if not too far separated, unite with extreme readiness, by the formation of intervening plastic material, which soon acquires great firmness. So rapidly is this process of repair carried on, that, according to Mr Paget, a specimen, six days after division, could bear the weight of 25 lbs.; while in another specimen, the new material, at the end of 21 days, bore a weight of 56 lbs. When the interval between the two ends of a tendon exceeds a certain limit, there will be only an imperfect bond of union, and either a partial or total loss of the use of the muscle will result. For details regarding this process of repair which has an

intimate bearing on the treatment of ruptured tendons, the reader is referred to Mr. Paget's admirable *Lectures on Surgical Pathology*.

Amongst the diseases of tendons, *inflammation* requires especial notice. 'Tendons,' says Mr Tatum, in his article upon *Affections of the Muscular System*, 'together with their sheaths, are not unfrequently inflamed. Independently of gout and rheumatism, the most frequent cause is a sprain or wrench in the neighbourhood of a joint. These injuries are occasionally productive of long-continued wearing pains, assuming much of a rheumatic character, and yield often slowly and unwillingly to the remedies, both local and general, employed in rheumatism.'—Holmes's *System of Surgery*, vol. iii. p. 544. In one of the forms of Whitlow (q. v.), known as *Paronychia gravis*, or *tendinous whitlow*, 'the tendons and their sheaths in the finger and hand are the seat of a severe and often most destructive inflammation, which, though often confined to one finger, not unfrequently extends to the hand and arm, attacking not only the tendons and softer parts, but exposing the bones, and disorganising the joints.'—*Op. cit.*, p. 544. It arises from slight punctures or wounds, with or without the inoculation of irritant or poisonous matter, and often without any apparent cause, except a derangement of the general health. It begins with severe and throbbing pain in the palmar surface of a finger, which extends upwards along the arm. There is extreme tenderness, and a certain amount of redness and swelling, with great tenseness of the parts. If the inflammation is not checked, suppuration soon ensues, accompanied by much constitutional disturbance. The matter frequently extends amongst the muscles, and in bad cases, occurring in unhealthy persons, the bones and joints become affected in the way already mentioned. In the early stage, free leeching, followed by hot fomentations, may be useful. The hand should be kept elevated, and an active purgative, with low diet, prescribed. If, as is often the case, these measures are unsuccessful, a free incision must be made along the centre of the palmar aspect of the finger—an operation which gives extreme relief, by removing the tension, and allowing the escape of blood, even if little or no pus is discharged. A generous diet, stimulants, and tonics, are now advisable; and under this treatment the disease generally yields; although cases occasionally present themselves in which the suppuration produces such results as to render amputation of the arm necessary, or even to cause death. A permanently bent finger, from adhesion of the tendon to its sheath, is a common result in severe cases of whitlow of this kind.

Tendons are not very unfrequently the seat of syphilitic enlargements or tumours. Malignant tumours scarcely ever spring from tendons, but fibrous tumours and small cartilaginous enlargements are often found in tendons.

Rupture of the tendons is an accident which is frequently caused by violent muscular action, especially if, from illness or other causes, the muscles have been for some time in a state of inactivity. The long tendon of the biceps cubiti is very obnoxious to this injury, which, in this case, is more often due to the disorganisation caused by chronic rheumatic gout than to mere mechanical violence. The other tendons most frequently ruptured are the tendo Achillis, and the tendons of the rectus femoris and the triceps humeri. When a tendon is ruptured or divided by a surgical operation (tenotomy), 'the part which is attached to the muscle is drawn away from the opposite end for about an inch. Blood is poured out between the ends, but much less than in rupture of muscles. The pain is said not to be very great; a considerable shock, however, is felt, as from a blow received on the part, accompanied by cramp of the muscle, and a perfect inability to use the limb; and in rupture of the tendo Achillis, a feeling is described as if the heel were sinking into a hole in the floor.'—Holmes's *System of Surgery*, vol. iii. p. 541. The essential point in the treatment of ruptured tendon is to keep the injured part in a state of constant rest and muscular relaxation, so that the separated ends may be approximated as much as possible, and to prevent any violent extension till firm union, by the process of reparation, has been established. The special methods of treating individual cases (as rupture of the tendons of the rectus femoris and the triceps, and of the tendo Achillis) are discussed in Holmes's *System of Surgery*, and other standard works on surgery.

TENE'BRIO. See MEAL-WORM.

TE'NEDOS (Turk. *Bogdsha-Adassi*), an island belonging to Turkey in the north-east of the Ægean Sea, off the coast of the Troad, and about 17 miles south of the western entrance to the Strait of the Dardanelles. It is about five miles long by two broad, rocky, but not unproductive, with a pop. of more than 6000, who are partly Greeks and partly Turks. The chief town, also called Tenedos, or *Bogdsha*, on the north-east coast, is the seat of a Greek bishop and Turkish aga, and carries on an active trade in wine.

TENERI'FE, the largest of the Canaries (q. v.).

TENERIFE, PEAK OF, or PICO DE TEYDE, a famous dormant volcano, the highest summit in the Canary Islands, stands in the south-west of the island of its own name, and is 12,182 feet above sea-level. The lower slopes of the mountain are covered with forests, or laid out in extensive meadows, yielding rich grass; but the upper ridges, and the Peak, properly so called, are wild, barren, and rugged in appearance. The Peak and its two inferior neighbours, the *Montana Blanco* and *Chajorra*, rise from a rugged circular plain of lava debris and pumice, 7000 feet above sea-level, about 8 miles in diameter, and fenced in on all sides by an almost perpendicular wall of rock. From the crevices of these mountains sulphurous vapours are constantly exhaling. The Peak can be seen from a distance of upwards of 100 miles; but the view from it is generally destroyed by the dense masses of cloud which hang over the surrounding sea at an average elevation of 4000—5000 feet, the sky above being almost uniformly clear and bright. Mr Piazzi Smyth, in the summer and autumn of 1856, made here a series of experiments for the purpose of ascertaining how far astronomical observation could be improved by eliminating the lower third part of the atmosphere, and with this object observed for two months, first on Guajara (an elevated peak of the rocky wall, 8903 feet high), and afterwards on Alta-Vista (on the side of the Peak, 10,702 feet high). See *Tenerife*, by C. Piazzi Smyth (London, 1858).

TENÈS, a rising seaport of Algeria, 100 miles west of the city of Algiers. It is happily situated for commerce, is the entrepôt for Orleansville, and the depôt for the supply of the army with provisions. It is at once fortunate in the agricultural resources of its territory, in its mineral wealth, and its position in respect to transit-trade. The population of the commune is about 8000.

TENE'SMUS (from the Gr. *teinein*, to strain) is the term employed in Medicine to designate a straining and painful effort to relieve the bowels when no fæcal matter is present in the rectum; the effort being excited by some adjacent source of irritation. All that is got rid of by the straining, which usually occasions more or less descent of the

gut, is mucus, frequently stained with blood. Tenesmus is a common symptom in dysentery, irritation of the bladder, stricture of the urethra, &c.

TENIERS, DAVID, the Elder, a Flemish artist of note, was born at Antwerp in 1582. For some years, he was a pupil of Rubens; afterwards, he visited Italy, where he studied under Adam Elzheimer, and on his return, settled in his native city, where he died in 1649. The subjects of T.'s pencil are in general very homely, and often low—the interiors and exteriors of public-houses, smoking-rooms, rustic games, weddings, &c.; but they are executed in the most vividly realistic manner, with such charm of colour, and happy ease of composition, that they never fail to excite in the beholder a lively sense of pleasure. T. was almost constantly employed during his career as an artist.

TENIERS, DAVID, the Younger, son of the preceding, was born at Antwerp in 1610. He received his first lessons in art from his father, who, it is said, subsequently placed him in the studio of Adrian Brauwer; but this statement can scarcely be true, for Brauwer (q. v.) was only two years older than himself. It is probable that he derived most, if not all his professional instruction from his father, to whose genius his own bore a peculiarly filial resemblance. In fact, the elder T. may be considered the founder of a school of which the younger is the most brilliant and prolific member. The latter, like his parent, rapidly rose into distinguished consideration, enjoying in the course of his life the favour and friendship of the Archduke Leopold, Queen Christina of Sweden, Don John of Austria, the Prince of Orange, the Bishop of Ghent, and other dignitaries. T. lived for the most part in a villa on the outskirts of Malines, where he had abundant opportunities of studying closely that humble rustic life which he has so charmingly depicted in all its aspects; but he died at Brussels, 11th February 1685. He was twice married: first to a daughter of the painter Breughel (q. v.), *Velvet* Breughel as he was called; and again to the daughter of a councillor at the court of Brabant. The number of his pictures is something marvellous. Smith, in his *Catalogue Raisonné* has carefully described 685. England is peculiarly rich in specimens, but they are also liberally scattered over the galleries and private collections of the continent, and, in spite of their number, bring great prices. They possess, but in a superlative degree, the beauties of the elder T.'s pieces. In the colouring of his skies, the sketching of his trees, the animation and grouping of his figures, we see everywhere the presence of a richer, finer, more observant and more imaginative genius.

TENNANT, WILLIAM, still to be remembered as the author of *Anster Fair*, was born at Anstruther, in Fife, in the year 1785. A cripple almost from his birth, and doomed to propel himself through life on crutches, he betook himself naturally to study, as requiring no exertion of the limbs. In 1799, he went to the neighbouring university of St Andrews, where, however, he only remained two years, leaving it to join his brother, a corn-agent, in business. In this, his success was indifferent; and in 1813, he was fain to accept the situation of parish schoolmaster at Denino, a small hamlet about four miles from St Andrews, with a salary of £40 a year. The year before, he had published his *Anster Fair*, a poem of much sprightliness and humour, notable as the first attempt to naturalise in our language the gay *ottava rima* of the Italians; soon after adopted by Byron with such splendid success in his *Beppo* and *Don Juan*. The piece gradually made its way, and in 1814 a highly laudatory notice of it appeared in the *Edinburgh Review*, from the pen of the then omnipotent Jeffrey. In 1816, Mr T. became teacher of a school at Lasswade, near Edinburgh, whence, three years afterwards, he transferred his services to the Academy of Dollar, in Clackmannanshire. His attainments as a linguist were extraordinary; and in 1835 he was appointed Professor of Oriental Languages in the university of St Andrews—a post for which, perhaps, not many men then living had similar qualifications. In connection with his new duties, he published, in 1840, grammars of the Syriac and Chaldee languages He died, on 15th February 1848, at his residence near Dollar, where his summers were usually spent. He was one of the most genial and amiable of men. Besides other miscellanies in verse, he gave to the world, in 1822, *The Thane of Fife, a Poem;* in 1823, *Cardinal Beaton, a Tragedy;* and in 1825, *John Baliol, a Drama.* None of these later productions had much success, or did anything to increase the literary reputation which his first work had won for him.

TENNESSEE′, a southern state of the American Union, the third admitted under the federal constitution, extends in lat. 35°—36° 30′ N., and long. 81° 37′—90° 28′ W., and is bounded on the N. by Kentucky and Virginia; and on the S. by Georgia, Alabama, and Mississippi. Area, 45,600 square miles. The chief towns are Nashville (the capital), Memphis, Knoxville, Columbia, Murfreesborough, and Jackson. The principal rivers are—the Mississippi, forming the boundary on the west; the Cumberland (q. v.); the Tennessee River, which twice crosses the state; the Obion, Hatchee, and numerous branches of the larger rivers, which give navigation and water-power to the entire state. Eastern T. is crossed by several ridges of the Alleghany Mountains, some of which have elevations of 2000 feet; the middle region between the Cumberland and Tennessee rivers is hilly, and the west level. The western portion of the state, between the Mississippi and the Tennessee, is of the alluvial and cretaceous formation of the shores of the Atlantic and Gulf of Mexico. Extensive iron mines lie between the Tennessee and Cumberland rivers. In the limestone regions are numerous caves, mostly unexplored. Several in the Cumberland Mountains are 100 feet deep, and miles in extent. A considerable river has been discovered in one at a depth of 400 feet; another opening perpendicularly in a mountain has never been fathomed. In some of these caves are large deposits of fossil bones of extinct animals. In the Enchanted Mountain are seen impressions of the feet of men and animals in limestone. Tracts of several acres have sunk into caverns a hundred feet deep. In many places are interesting remains of ancient mounds and fortifications.

The climate of T. is temperate, and, except in some of the river-bottoms, salubrious. The soil of the whole state, except the eastern mountainous regions, is extremely fertile, producing cotton, tobacco, Indian corn, wheat, figs, peaches, grapes, and all the fruits and productions of the southern temperate regions. The state is richly wooded with pine, oak, hickory, sugar-maple, cedar black walnut; and the woods abound in game, as bears, deer, opossums, racoons, foxes, &c.; and the country is rich in horses, cattle, sheep, and swine—the last running in large herds in the woods, and fattening on nuts. In 1860, the lands of T. were valued at $271,358,985, and in 1870 at $218,743,747, showing a decline of $52,615,238. In 1870, the live stock was estimated at $55,084,075; and the crops consisted in part of 41,343,614 bushels Indian corn, 6,188,916 bushels wheat, 21,465,452 lbs. tobacco, and

181,842 bales of cotton. The commerce of the state, by its rivers and 23 lines of railway, is chiefly with New Orleans, St Louis, and Cincinnati. There are state asylums for the deaf and dumb at Knoxville, and for the insane and blind at Nashville. There are 51 colleges; a common-school income of $683,000; 3180 churches, chiefly Methodist, Baptist, and Presbyterian; 13 daily and 65 weekly papers. In 1870, the taxable property was $253,782,161; revenue, $3,381,579; state debt, $38,539,802.

In 1756, a settlement was formed near Knoxville, then a part of North Carolina. Nashville was settled near the close of the Revolution; in 1790, T. was organised as a territory with Kentucky; and in 1796 was admitted into the Union as a separate state. In January 1861, a proposal to secede from the Union was defeated, but in June it was carried by a majority of 57,667. In ten months the state raised 50 regiments for the Confederacy; 5 or 6 were also recruited for the Union. The state was the scene, at Knoxville and Chattanooga, of some of the most important operations of the war. In March 1870, a new constitution, recommending and providing for a common-school fund, was ratified by a large majority of the people. For some years after the close of the war of secession, portions of T. were in a disturbed condition, bands of disguised marauders forcibly entering houses and hanging and shooting citizens. The pop. of T., in 1800, was 105,602; 1820, 422,813; 1840, 829,210; 1860, 1,109,847, of whom 275,784 were slaves; 1880, 1,542,359.

TENNESSEE, a river of the United States, the largest tributary of the Ohio, has its origin in the union of the Clinch and Holston, which rise in the Alleghany Mountains of South-western Virginia, and flowing south-west in two parallel valleys, unite at Kingston in the west of Tennessee state. The river flows still south-west, in the Alleghany valley, entering Alabama close by the north-west corner of Georgia, whence it flows 60 miles further in the same course, then turning to the west-north-west, re-enters Tennessee at the north-east corner of Mississippi, flows northwardly across the state, then north-west across Kentucky to its confluence with the Ohio at Paduca; length 800 miles, or, from the source of the Holston, 1100. Its chief branches are the Sequatchie, Paint Rock, Flint, Duck, North Branch, Hiawassee, Big Sandy, and Clark's. It is navigable 259 miles to Mussel Shoals—a series of broad shallow rapids—and 500 miles above. Chief towns, Florence and Decatur, in Alabama; and Chattanooga, Tennessee.

Tenney.

TE'NNEY, in Heraldry, orange colour, one of the tinctures enumerated by heralds, but not of frequent occurrence in coat-armour. It is indicated in engravings by lines in bend sinister, crossed by others barways.

TE'NNIS, a game of great antiquity, belongs to the class of ball-games, and finds its analogies in the *sphairisis* of the Greeks, and the *pila* of the Romans. Under the name of *paume*, a name given to it from the ball being at that time struck with the palm of the hand, it is noticed in the Arthurian romances, and in the earlier records of the dark ages. In the 15th c., it was in great vogue in France among all classes, from the monarch to the meanest of his subjects; and about this time the use of a heavy glove to protect the hand in striking the ball was introduced, and a further improvement was subsequently effected by the adoption of the *racket*. The game in England kept pace with its progress in France, and during the 16th, 17th, and 18th centuries, was generally practised under the name of *tennis*, especially by the higher classes. Many modifications have been introduced from time to time, and the legitimate descendant of the paume and tennis of former days is the present game of rackets. 'Rackets' is played in a court 96 or 97 feet long, by 33 or 34 feet wide, and surrounded by walls sufficiently high to prevent the balls from being lost. The players are either two in number, or four divided into two parties. The player or party 'in' *serves* the ball against the head-wall of the court, so as to rebound over a line drawn at a certain distance; it is returned by means of the racket by the player or party 'out,' who must make it rebound from the wall to the other side of the line; and the game is thus carried on till one player fails to strike the ball or cause it to rebound properly. If the player 'in' fails, he changes places with the player 'out;' if the latter fails, the former scores a point. The part of the court on which the player or party in is placed is called the 'service' side; the other, the 'hazard' side. A similar game played without the racket is called *fives*, *hand-tennis*, or *hand-ball*.

TENNYSON, Alfred, was born in the year 1810 at Somersby, in Lincolnshire, of which parish his father was rector. He was the third of a large family, several other members of which shared with him in some measure the genius which has won for him undisputed rank as the first English poet of his time. Very early, the bent of nature became obvious; and in 1827, T., along with his brother Charles, issued a small volume, entitled *Poems, by Two Brothers*, of which almost nothing has been preserved. Having gone to complete his education at Trinity College, Cambridge, he gained in 1829 the Chancellor's Medal by a poem in blank verse, entitled *Timbuctoo*, in which there is plainly to be traced some impress of his peculiar genius. His literary career, however, may properly be said to date from 1830, in which year a volume appeared of *Poems, chiefly Lyrical*, by Alfred Tennyson. It was not received with great favour by the public; but amid much that was weak and immature, it contained pieces which in no indistinct manner announced the advent of a true poet. In a notice of the book by Professor Wilson, in *Blackwood's Magazine*, the promise of the young writer was recognised in sufficiently express terms. The praise was, however, not unmixed with censure, which, though it seemed on the whole judicious, did not commend itself as such to the poet, who retaliated on 'crusty Christopher' in his next volume, published in 1833. This consisted of a selection of poems from the previous one, carefully retouched by the writer, with the addition of pieces produced in the interval, many of which have scarcely been surpassed in beauty by anything he has since produced. Onward from this time, the reputation of the writer slowly but surely extended itself; and the publication, in 1842, of *Poems, by Alfred Tennyson*, in two volumes, raised him to the position of absolute supremacy which he has ever since continued to occupy by almost universal consent. In these he included whatever in his earlier issues he deemed worthy of preservation, and the work was substantially what we now buy as *Tennyson's Poems*. In 1847 appeared *The Princess, a Medley*; and in 1850, the series of elegies entitled *In Memoriam, A. H.*, a tribute of affection to the memory of Arthur Hallam, a son of the eminent historian, and the chosen friend of the poet in his earlier years at Cambridge. On the death of Wordsworth, in 1850, T. succeeded him as poet-laureate, in which capacity he issued, in 1852, his *Ode on the Death of the Duke of Wellington*, a piece which, as in a manner 'done to order,' can scarcely take rank as one of his happiest

effusions. This—if we except some simple and touching lines, evoked by the death of the Prince Consort—is happily the sole attempt hitherto made by T. in emulation of Pye and others. In 1855 appeared *Maud, and other Poems.* The immediate reception of this little volume was not enthusiastic. While many of its lyrics instantly caught the public ear, *Maud*, as a whole, at first rather puzzled the critics, and was little better than 'caviare to the general;' and though since it has risen in estimation, the subtle and recondite art exhibited in the structure of the poem is probably even now appreciated by only a few of its admirers. But for any little falling off in T.'s popularity on this occasion, a noble *amende* was made him on his next appearance. *The Idylls of the King*, published in 1859, were everywhere received with enthusiasm. This work at once took rank as one of the noblest poems in our language. In 1864, we had from T. a volume, containing *Enoch Arden*, one of his most finished and successful works; *Aylmer's Field;* a short piece, *Tithonus*, consummate in its beauty and finish; in 1870, *The Holy Grail; Pelleas and Ettare;* and *The Windows or Songs of Wrens*, set to music, which appeared the same year; and in 1872, *The Tournament* and *Gareth and Lynette.* T. has lived for the most part retired, not much caring to cultivate 'society,' by itself so called, but greatly beloved, it is understood, by the circle of his more intimate friends. In 1850 he was married to Miss Emily Sellwood, and subsequently resided in the Isle of Wight until 1869, when he removed to Petersfield, Hampshire. In 1883 he was raised to the peerage as Baron Tennyson d'Eyncourt of Aldworth.

It is not an easy matter to criticise the poetry of T. dispassionately, so deeply is one apt to become enamoured of its beauties. His verse is the most faultless in our language, both as regards the music of its flow and the art displayed in the choice of words. Nowhere in literature is the *callida junctura verborum* so wondrously seen. As a painter, no modern poet has equalled him. But it is neither to his colour nor to his music alone that he owes his great popularity. His *virtue* as a poet doubtless lies in these things; but the pleasure which his poetry gives springs largely from the cordial interest he displays in the life and pursuits of men, in his capacity for apprehending their higher and more beautiful aspirations, and in a certain pervasive purity and strength of spiritual feeling.

TE'NON, in Carpentry, the square end of a timber, reduced about ⅓d its thickness, to fit the mortise or socket in another timber, so as to join the two together.

TENOR, in Music, one of the four classes into which voices are divided in respect of their compass. It is the higher description of adult male voice, and generally extends from  to . Music for tenor voices is most properly written on the tenor or C clef, , in which its principal tones come within the staff; but the treble clef is occasionally used, with the notes written an octave above their true pitch.

TENO'TOMY, or the Division of Tendons, is a comparatively recent surgical operation, whose object is to relieve some variety of deformity by severing a permanently contracted muscle at its tendinous portion. The invention of subcutaneous tenotomy is due to Stromeyer (1831), and a lucid account of the history of this operation is given by Dr Little in his *Treatise on Club-foot and Analogous Deformities* (Lond. 1839). The various kinds of knives that have been devised for severing tendons are termed *tenotomes.* The affections in which tenotomy is advantageously employed are club-foot, contractions of the upper extremity from spasm and paralysis, deformity from diseases of the palmar fascia, torticollis or wry-neck, anchylosis of the knee and other articulations, and squinting.—For further details, the reader is referred to the above-mentioned work by Dr Little, and to the same author's treatise *On the Deformities of the Human Frame* (Lond. 1853).

TE'NREC, or TANREC (*Centetes*), a genus of Mammalia, nearly allied to moles and hedgehogs, usually ranked in the family *Erinaceidæ.* The tenrecs are incapable of rolling themselves up like hedgehogs. They are nocturnal animals, natives of Madagascar and the Mascarene Isles. Three species

Tenrec (*Centetes ecaudatus*).

are known. They are remarkable for spending the hottest part of the year in a dormant state, as some animals in arctic regions spend the winter. Their flesh has a very peculiar flavour, but is acceptable to the natives of Madagascar.

TENSE (Fr. *temps*, from Lat. *tempus*, time), in Grammar, designates a set of changes which verbs undergo in order to mark the time of the action. See CONJUGATION.

TENT (Lat. *tentorium*, from *tentus*, stretched). Without speculating on the relative priority of tents and other forms of human dwellings, it is safe to assume, that among nomadic tribes, some shelter, easily framed and portable, must have been felt to be a primary necessity. The skins of animals, or the larger kinds of foliage, would form the earliest coverings, for which textile fabrics would be substituted as civilisation advanced. In the book of Genesis, the patriarchs, Noah, Abraham, Lot, Isaac, Jacob, are represented as dwelling in tents, probably much the same as the modern Arab tents, which are large structures, very

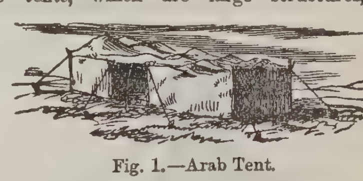


Fig. 1.—Arab Tent.

rude in form, covering a considerable space of ground, but of small height. Among the Nineveh sculptures is a representation of the tent of King Sennacherib, which, like modern tents, was supported by ropes: numerous tents of the officers and common people are likewise shewn.

The early Greek, and afterwards the Macedonian

tents were small coverings of skins, under each of which two soldiers slept. Alexander the Great is said to have had a pavilion of extraordinary magnificence. Its roof, one mass of gilded embroidery, was sustained by eight pillars covered with gold. In the centre, was the royal throne; and 100 beds could be made up within the temporary edifice.

The Roman soldiers seem to have used two sorts of tents—one, a tent proper, of canvas or some analogous material, and constructed with two solid

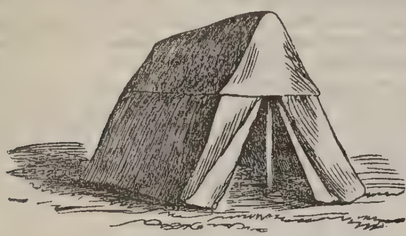

Fig. 2.—Roman Tent.

upright poles, and a roof-piece between them; the other, more resembling a light hut, of a wooden skeleton, covered by bark, hides, mud, straw, or any material which afforded warmth. Of these tents, the poles of the first would have been too cumbrous for carriage, and were probably cut afresh at each halting-place; the latter was evidently unsuited to removal, and was most likely only erected for winter-quarters, or a long sojourn. The Roman tent held 10 soldiers, with their *decanus*, or corporal.

In Persia, there are many tribes who pass their whole time in tents, which, naturally, they have brought to considerable perfection. They make them nearly hemispherical, with a wooden framework, and covered with felt, while worked hangings close the aperture. This felt admits of the exhibition of much taste in its decoration.

The Chinese lower orders live much in tents. They are ordinarily of matting. These people are

Fig. 3.—Chinese Tent.

clever in their construction, and make them of great size, and with considerable comfort.

Modern military tents are all made of linen or

Fig. 4.—Bell-tent.

cotton canvas, supported by one or more poles according to shape, and held extended by pegs driven into the ground. British tents comprise the hospital-marquee, a large oblong tent with high side-walls; and the round-tent, or bell-tent, for troops. The latter is 12 feet 6 inches in diameter, 10 feet 4 inches high, weighing, with all its appurtenances, 68 lbs., and giving sleeping accommodation to 16 men; the appurtenances comprise 2 mallets, 50 pins, 20 ropes, 20 loops, and 2 long ropes, for use in storms in giving additional firmness round the central pole. In modern tents, there is a low side-wall of canvas, to give greater room inside. These tents are said to be comfortable and moderately healthy, if floored with tarpaulin, vulcanised india-rubber, or other waterproof material. The great drawback is the tendency to blow over. To obviate this, and the inconvenience arising from the conical shape, Major Rhodes, a British officer, has invented a new tent, which has found much favour with the military authorities of this and other countries. He does away with the

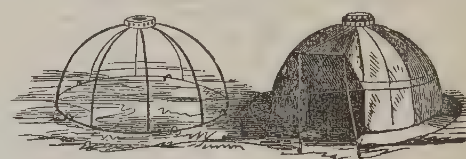

Fig. 5.—Major Rhodes's Tent.

central pole, and has a circular frame, hingeing in the centre like the ribs of an umbrella, over which the canvas is stretched. It is claimed for this tent, that it is more roomy than the regulation-tent, in proportion to its weight, is better ventilated, and possesses far greater stability.

TENTA'CULITES, a genus of obscure annulated tapering shells, found abundantly in some strata of Silurian age. They are generally referred to annelids, but the structure of the shell seems to exhibit greater affinities to recent pteropodous molluscs.

TE'NTERDEN, a municipal borough and market-town in the Weald of Kent, 18 miles south-south-east of Maidstone. The church, which contains portions of Early English, is surmounted by a massive and lofty perpendicular tower. Tradition asserts, that a quantity of stones, which had been got together for the purpose of strengthening the sea-wall of the Goodwin Sands, were employed in the building of this tower, and that when the next storm came, the district of Goodwin Sands, which had formerly belonged to the mainland, was submerged. Thus arose the popular saying, that 'Tenterden steeple was the cause of the Goodwin Sands.' Pop. (1881) 3620.

TENTERDEN, Charles Abbott, Lord, a distinguished English lawyer, was born at Canterbury, on the 7th October 1762. He was the son of a hairdresser. Being admitted on the foundation of the King's School connected with the cathedral, he distinguished himself by perseverance and extreme accuracy. A small exhibition in the gift of the chapter enabled him to proceed to Oxford, where, in 1781, he was elected scholar of Corpus Christi College; and a few years later, he obtained what were then the chief distinctions at the university, the Chancellor's two gold medals, one being for English, the other for Latin composition. In due time, he became a Fellow of his college. After being a student of the Inner Temple, in 1795, he was called to the bar. He joined the Oxford circuit; and in spite of a husky voice, a leaden and unmeaning countenance, and painfully timid manners, his great activity of mind, good taste, scholarship, scientific and legal

knowledge, were soon appreciated, so that he rapidly acquired a large business. He published, in 1802, his treatise *On Merchant Ships and Seamen*, in all respects the best written book which had till then appeared on one department of English law. It had the effect of increasing his employment in the more lucrative mercantile causes; and in 1807, it appears from his income-tax return that his fees amounted to upwards of £8000. In 1816, he accepted a puisne judgeship in the Court of Common Pleas; and in 1818 he was knighted, and chosen to succeed Lord Ellenborough as Chief-justice of the King's Bench. As a judge, his most marked characteristic was his evident impartiality and freedom from bias. The comparative leisure he enjoyed on the bench he spent in reading the classics and in the study of botany. He was, in 1827, raised to the peerage. In the House of Lords he was the most influential speaker against the Catholic Relief Bill; and in his last speech, he made a vow that if the Reform Bill, that 'appalling bill,' passed, he would never again take his seat as a peer. The success of the measure, it is believed, affected his health. He was seized with a violent attack of inflammation in November 1832, when presiding at the trial of the mayor of Bristol for misconduct during the riots, and he died there on the 4th of that month.

TENUIRO'STRÉS, a tribe or sub-order of birds, of the order *Insessores*, characterised by a lengthened slender bill, which is sometimes straight, sometimes curved. Some of them feed on insects, some chiefly on the honey of flowers. To this tribe belong the Creepers (*Certhiadæ*), Sun-birds (*Cinnyridæ*), Humming-birds (*Trochilidæ*), and Hoopoes (*Upupidæ*).

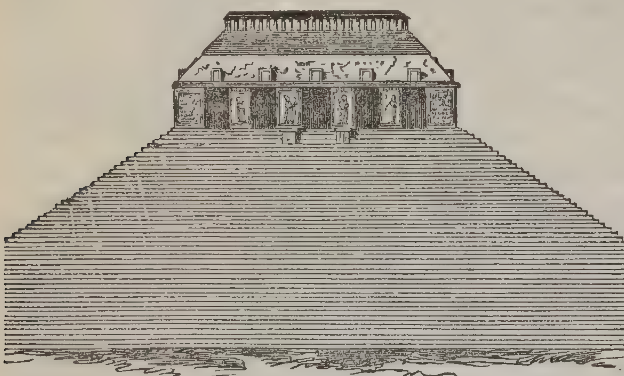
TENURE OF LAND, in England, was an accompaniment or immediate consequence of the Feudal System (q. v.) established during the middle ages throughout the greater part of Europe. Feuds were introduced by the barbarous tribes who poured themselves into the Roman Empire during the 4th, 5th, and 6th centuries. The chief feature of feuds was, that the lands of the conquered country were parcelled out to the leaders, on the condition of bearing arms whenever the sovereign required them. The relation thus created between sovereign and vassal was called a feud. The grantee held his lands at first for life only, but gradually it was developed into a hereditary character, and also into one which admitted of subinfeudation, i. e., the parcelling out of the feudal land among vassals of the head vassal, who was the lord of his own vassals. This kind of relation between lord and vassal gradually was extended to all kinds of land, for the owners of allodial land voluntarily surrendered their land to some lord, so as to have the same advantages. The vassal did homage to the lord, and took the oath of fealty. Besides these characteristics, the holding came to be attended with the following incidents. 1. An aid, which was a payment granted to help the lord in his necessities. 2. A relief was a tribute paid by a new tenant on succeeding to his predecessor. 3. A fine was paid by a tenant to the lord on alienating the lands to a purchaser. 4. An escheat or forfeiture was the reverting of the estate to the lord when there was a failure of heirs or some violation of duty on the part of the vassal. The feudal system was extended to England by the Norman barons soon after the Conquest, with the concurrence of William I., much to the dislike of the Saxons, whose grievances grew until they found vent in Magna Charta, which was in fact an attempt to restore their earlier constitution. The chief fiction, however, of a relation between the crown and the holders of land was not got rid of. The crown was nominally the lord paramount, and there were intermediate lords called mesne lords, of whom the tenants held. Gradually, the kinds of tenure were classed under free and base services—the former being those which a freeman might perform, as serving in war, or paying a sum of money; the latter, such as a peasant might perform, such as ploughing the lord's land, &c. These were afterwards further distinguished according to the certainty or uncertainty of the extended services to be performed. Ultimately, the tenures were classed as three. 1. *Knight-service*, or chivalry, i. e., holding on condition of serving in the war, and taking the oath of fealty. This was accompanied by the incidents of descent, wardship (or guardianship of the knight's heir by the lord), marriage (i. e., the lord's right to give the knight's infant in marriage), aids, reliefs, primer seisin (i. e., one year's profits from an heir on his succession), fine, escheat, and forfeiture. These incidents gradually grew irksome. James I. proposed to commute knight-service into an annual fee-farm rent; but this not being done, the statute of 12 Ch. II. c. 24 swept the whole away, and converted it into free socage. 2. *Free socage* was a tenure by some certain and determinate service, as by paying a small fixed rent, or ploughing the lord's lands for a fixed number of days. The incidents were rather less burdensome than those of knight-service, being descent, wardship, marriage, and reliefs, primer seisin, fines, escheat, and forfeiture. These incidents were all abolished by the above statute of 12 Ch. II. c. 24, and the tenure of free socage is now generally known as freehold. 3. *Villenage service*, or Copyhold Tenure (q. v.), which still exists nearly in its original state. The result is, that in England at the present day the two tenures are freehold and copyhold. The leading characteristic of freehold is, that practically the feudal relation between the crown and the holder is cut off, and the holder is entirely his own lord and master, can sell the estate, devise it by will, give it away, and do what he likes with it free from any interference or payment to the crown. As to copyhold, the feudal relation is kept up to a certain extent between the lord and the copyhold tenants, who must in form pay rents more or less nominal, and fines and Heriots (q. v.) to the lord on alienating the lands or succeeding thereto. Yet, practically, the copyholder does not materially differ from a freeholder except that he is liable to these petty and harassing acknowledgments towards a stranger; and by recent statutes, he can compel the lord of the manor to commute these fines and incidents, and convert the tenure into freehold.

In Ireland, the tenure of land is almost identical with that in England.

As to Scotland, there is a marked difference between the tenure of lands there and the tenure in England. At the present day, the feudal system prevails to a great extent, resembling in many respects the English copyhold tenure. Every piece of land there has generally its lord or superior and its vassal, that is to say, the vassal has the *dominium utile*, or actual enjoyment, while the superior has a kind of superior interest, or *dominium directum*, which consists in his drawing a rent called a feu-duty, which the vassal is bound to pay, or to forfeit the land. On each alienation or death of the vassal, there must be certain forms superadded, implying a consent or recognition by the superior, and certain casualties or additional payments must be made on such occasions. Recent statutes have tended to extinguish several of these superfluous forms, and make the vassal more independent. But a great many remain unaltered. And not only is there this feudal relation between the crown and its vassals, but these may subdivide the property and create

intermediate estates without limit, each vassal being in turn the superior to his subvassal; and this endless chain of relationships complicates the conveyancing still more. See CONVEYANCING; FEU.

TEOCA'LLI (House of God), the name given to the temples of the aborigines of Mexico, of which many still remain in a more or less perfect state. They were built in the form of four-sided pyramids, and consisted for the most part of two, three, or more stories or terraces, with the temple, properly so called, placed on a platform on the summit. The largest and most celebrated is the pyramid of Cholula, measuring 1440 feet each way, and 177 in



Teocalli at Palenque.

height; it is much defaced, and the temple on its summit has been removed. The teocallis in Yucatan are in far better preservation; they are not generally built in terraces, but rise at an angle of 45° to the level of the platform, with an unbroken series of steps from base to summit. The temples on their summit are sometimes ornamented with bas-reliefs in stucco and hieroglyphic tablets, and the roof is formed by courses of stone approaching each other, and furnished with projections like dormer windows. The preceding woodcut gives the elevation of a large teocalli of this kind at Palenque, on a scale of 50 feet to the inch. Not unlike the teocallis are the palaces of the Aztec kings or chiefs, which differ from them in having the pyramid smaller, less prominent, and oblong in plan, while the building, larger and more elaborate, consists for the most part of a stone basement, with square doorways, but without windows, surmounted by a structure which appears to be directly copied from wood-work. On some of these façades, we have also rude pillars and grotesque carvings, and there are often a number of chambers in the interior. A palace and temple are sometimes found attached together; and in a few cases, the most remarkable of which is the Casa de las Monjas, at Uxmal, the buildings stand round a courtyard. See MEXICO.

TEPIC, Mexico. See SUPPLEMENT in Vol. X.

TERA'MO (anc. *Interamna*), a town of Southern Italy, in the province of Abruzzo Ultra I., at the junction of the Tordina and Vezzola, 28 miles north-east of Aquila. It is well-built, with long and rather wide streets, has a cathedral, a public library, a foundling-hospital, and a botanic garden, carries on an active trade in corn, wine, and olives, and has a population of 19,721.

Ancient *Interamna* (of which the name T. is an Italianised form) was a city of Picenum, in the territory of the Prætutii. In the middle ages, it also bore the name of Abrutium or Aprutium (supposed to be a corruption of Prætutii), whence the modern name of the district, Abruzzo. Vestiges of the ancient city—the amphitheatre, temples, baths, aqueducts, &c.—are traceable, and many statues, altars, and inscriptions have also been discovered. In the plain below T. took place, July 27, 1460, between the army of John, Duke of Anjou, and the Milanese allies of Ferdinand I. of Aragon, one of the most sanguinary battles ever fought in Italy. After the contest at Castelfidardo (1860), T. was the first Neapolitan city that opened its gates and gave joyful welcome to King Victor Emmanuel.

TE'RAPHIM (Heb. plur.), a word of uncertain derivation (connected by some with Serapis), denoting certain images, idols, or household gods occurring in the Old Testament, which were consulted as oracles, and probably even worshipped to a certain extent. The gods which Rachel stole are called Teraphim, and Saul was reproached by Samuel for stubbornness which is like Teraphim; his daughter placed a Teraph into David's bed to conceal his flight, &c. There is no proof that this veneration for Teraphim was not held perfectly compatible with the worship of Jehovah, spite of some reformatory attempts to sweep them away. Many and curious have been the explanations given of the nature of the Teraphim by different scholars in and out of the synagogue. A vague but generally prevailing notion is that of their having been a kind of astrological automata, which somehow or other could be made to move, and to utter certain sounds. All that is certain, however, is only the fact, that the real meaning and character of this strange idol had been forgotten already at a very early period.

TERATO'LOGY (Gr. *terata*, wonders, or monsters) is a term used in Physiology as synonymous with 'The History of Monstrosities or Anomalous Formations.' See MONSTROSITY.

TE'RBIUM, a very rare metal, whose oxide, *Terbia*, is found in association with the rare earth Yttria, the oxide of Yttrium (q. v.).

TERBURGH, GERHARD, a Dutch painter, belonging to an old and respectable family of Zwoll, was born in 1608, studied first under his father, who was also an artist of note, and afterwards visited Germany, Italy, Spain, England, and France. On his return to his native country, he settled at Deventer, of which town he became burgomaster, and died in 1681. The elegant ostentatious life of his time, with its superfine courtly manners, and splendid costume, found in T. an admirable painter. The central figure in many of his pictures is a young lady with fair hair, and dressed in white satin. His most famous piece, however, is a picture containing portraits of the 69 plenipotentiaries who drew up the Treaty of Westphalia. In Dr Waagen's opinion, T. is the real founder of the art of painting conversation-pieces, and at the same time the most eminent master in this style. 'In delicacy of execution, he is inferior to none; and in a certain tender fusing of the colours, he excels all others; but none can be compared with him in the enchanting harmony and silvery tone, and the observance of the aërial perspective. His figures, which are well drawn, have an uncommon ease of refinement, and are frequently very graceful.' T.'s works are to be found in various English collections, particularly those of Sir Robert Peel, the

Duke of Sutherland, Lord Ashburton, Mr Hope, the Marquis of Bute, and Her Majesty; as also in the galleries of Dresden, Munich, Vienna, the Louvre, Amsterdam, and Berlin.

TERCE (Lat. *tertia*—i. e., *hora*, the third hour), one of the 'Lesser Hours' of the Roman Breviary, so called from the time of the day for which it is fixed. See CANONICAL HOURS.

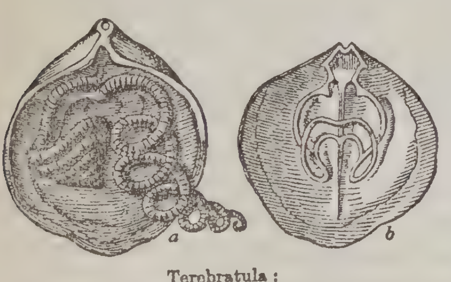
TERCE, in the Law of Scotland, is the interest or estate which a widow has in the land of her deceased husband at common law. This amounts to a liferent of one-third of such estates. In estimating the estate of the husband, all real burdens must be first deducted, and certain other things—as the mansion-house, if there is only one, superiorities, and patronage, leases, and feu-duties. The mode by which a widow completes her title to the terce is by a process called *kenning to terce*, the object of which is to separate her portion from the rest, which goes to the heir, so that each may possess independently his and her portion respectively. She is then in the position of an ordinary proprietor for life. Though terce is a legal right, yet this right of the widow may be modified by an antenuptial contract, under which she is otherwise provided for.—In England and Ireland, a widow has a similar right, called Dower (q. v.).

TERCEI'RA, one of the Azores Islands (q. v.), and the second in size of that group, forms one of the central cluster, and lies eastward from San Jorge. Area, 220 sq. m.; pop. between 40,000 and 50,000. Steep rocks of lava almost everywhere line the coast; the island is accessible only at few places, and these are defended against invasion by fortifications. The soil is fertile; the plateaux of the mountains afford excellent pastures, and cattle-breeding is an important branch of industry; the principal articles of export are wine, timber, and orchil. Chief town of the island, Angra, the capital (pop. 18,000), in the fort of which reside the governor and the bishop of the Azores.

TEREBINTA'CEÆ. See ANACARDIACEÆ.

TEREBRA'NTIA, a section of the insect order *Hymenoptera*, distinguished by the females having an ovipositor. To this section belong Sawflies (*Tenthredinidæ*), Ichneumons, Gall-insects, &c.

TEREBRA'TULA, a genus of deep-sea brachiopodous mollusca. The animal is attached to the shell by a pedicle, and the brachial disc is three-lobed, the centre lobe being elongated and spirally convoluted. The shell is smooth, with a truncated



Terebratula:
a, valve with the spiral arms; b, valve with arms removed.

perforated beak, the foramen being circular. The shelly loop is very short and simple. The shell of this genus, and some of its allies, is covered with minute quincuncial perforations, sometimes visible to the naked eye, but usually requiring a lens of a low power to distinguish them. The generic title is now restricted to shells with a short internal loop. The species with long loops are grouped together under the name *Waldheimia*. Of the restricted genus, there is only a single living species (*T. vitrea*); but the fossil species are more than a hundred in number, and are found in all periods of the earth's history, from the Devonian age upwards.

TERE'DO, a genus of lamellibranchiate molluscs of the family *Pholadidæ*; very much elongated, and worm-shaped; the mouth very delicate, open in front and at its lower part, for the passage of the short foot; the shell rather thick, equivalve, destitute of hinge, gaping at both ends. The species are rather numerous, and are generally known by the name of SHIPWORM or PILEWORM, because they

Common Shipworm (*Teredo navalis*).

perforate and live in timber. Their perforations are made in the direction of the grain of the timber, except when a knot is met with, or the shell of another *Teredo*, when they accommodate themselves to circumstances by bending. The cavity is lined with a calcareous incrustation. The aperture by which the T. enters is small, and it grows within the cavity which it makes. Two small valves form the true bivalve shell; the calcareous tube encloses the worm-shaped body of the animal. Its growth is very rapid, and its ravages are often terrible. A piece of deal has been found riddled by shipworms after forty days' immersion. Ships, piles, and all submarine woodwork are destroyed by it. Copper-sheathing is employed to protect ships from the shipworm, or the timber is driven full of short, broad-headed nails, the rusting of which forms a coating which it does not penetrate. The dykes of Holland have been threatened with destruction by its ravages. The COMMON SHIPWORM (*T. navalis*) is said to have been introduced into Europe from warmer climates. It is now, however, extremely abundant in European seas. In the East Indies, a very large species (*T. gigantea*) is found, generally in shallow water among mangrove trees; it is sometimes more than five feet in length, and at the thickest part three inches in diameter.

TERE'K, one of the most considerable streams of the Caucasus, rises near the lofty Mount Kasbec (about 17,000 feet high), flows north-west through the defiles of the mountains, crossing the district of the Kabarda, and reaches the border of the government of Stavropol, where it curves eastward, forming the south boundary of that government, until, reaching Kisliar, it divides into numerous branches, which form a delta 70 miles broad, and 50 miles long from apex to base, and falls into the Caspian Sea. It is not navigable. Total length estimated at from 300 to 390 miles.

TEREN'TIUS A'FER, PUBLIUS, the comic poet, was born at Carthage, 195 B. C. By birth or purchase, he became the slave of the Roman senator P. Terentius Lucanus, who, out of regard to his handsome person and unusual talents, educated him highly, and finally manumitted him. On his

manumission, he assumed, of course, his patron's *nomen*, Terentius. His first play was the *Andria*, written in his 27th year, but not acted till 166 B. C. Its success was immediate, and introduced its author to the most refined society of Rome, where his engaging address and accomplishments made him a particular favourite. His chief patrons were Lælius and the younger Scipio, after living with whom in great intimacy for some years in Rome, he went to Greece, where he translated 108 of Menander's comedies. He never returned; and the accounts of how he came by his death are conflicting. He is supposed to have died in his 36th or 37th year, leaving one daughter. Six comedies are extant under the name of T., which are perhaps all he produced—viz., *Andria*, *Hecyra*, *Heauton-timoroumenos*, *Eunuchus*, *Phormio*, and *Adelphi*. In conjunction with Plautus, T., on the revival of letters, was studied as a model by the most accomplished play-writers. His language is pure almost to being immaculate, and though inferior to Plautus in comic power, he is more than his match in consistency of plot and character, in tenderness, in wit, and in metrical skill. His plays have an educational value, as dividing, with the works of Cicero and Cæsar, the honour of being written in the purest Latin. They have been translated into most of the European languages. The best editions are those of Bentley (Cambridge, 1726), and the recent one of Parry (1857).

TERESA, St, one of the most remarkable of the female saints of the modern Roman calendar, and the most admired of the modern mystic writers of that communion, born at Avila, in Old Castile, March 28, 1515, was the daughter of Alfonso, of the noble House of Sanchez de Ceyeda. Even as a child, T. was remarkable for piety of a most enthusiastic kind; and when she was but seven years old, she and her little brother, Rodrigo, fled from her father's house, with the design of offering themselves for the crown of martyrdom among the Moors, but were overtaken, and restored to their parents. Her mother died while she was still young, and she was educated in a convent at Avila, from which, however, she was compelled by illness to return home when she was in her 16th year. During her illness, she resolved, notwithstanding the very earnest opposition of her father, to become a nun, and having in her 18th year entered a convent of the Carmelite order in her native city, she made her solemn vow on the 3d November 1534. In this convent she continued to reside for nearly thirty years, but it was not till about the year 1539, that her constitution became strong enough to permit her to follow, even in an imperfect way, the observances of conventual life. Her own account of her mental and spiritual condition during this period, which extended to the year 1555, is extremely interesting, and, like the confession of St Augustine and other saints, has furnished endless materials to the spiritualists of more recent times. The change of heart and of purpose came in 1555—1556, and was as complete and decisive as her former condition had been purposeless or fluctuating. After a time, her religious exercises reached a most extraordinary degree of asceticism. Her prayers were almost continual, and she was reported to be favoured with visions, ecstasies, and other supernatural visitations, of which many curious details are related by her biographers, and in her own letters and papers. The fame of her sanctity spread not only throughout Spain, but into almost every part of the church. By some, the reality of the reported supernatural favours which were ascribed to her was called into question; and there were even some who threatened to invoke the rigorous investigation of the Holy Office; but the popular voice was freely accorded to her, and the authority of St Francis Borgia, St Peter of Alcantara, and other high names, eventually disarmed the opposition. The most notable and permanent fruit of the enthusiastic spirituality of T. is the reform of the Carmelite order, of which she became the instrument. She commenced this work in concert with a few zealous members of her own sisterhood in the convent at Avila, where she had resided from the date of her profession; but after a time, she obtained permission from the Holy See, under the direction of Peter of Alcantara, to remove with her little community to St Joseph's, a small and very humble convent in the same city, where she established in its full rigour the ancient Carmelite rule, as approved by Innocent IV. in 1247, with some additional observances introduced by T. herself. This new convent was established in 1562, and in the end of that year, or the beginning of 1563, T. took up her abode therein; and in 1565, she obtained from the pope, Pius IV., a formal approval for the rule as modified by her. For two years, T. lived in great privacy and quiet in her convent of St Joseph; but in 1567, the general of the Carmelite order, F. Rubeo, was so struck, during his visitation of the convents at Avila, with the condition of that over which T. presided, that he urged upon her the duty of extending throughout the order the reforms thus successfully initiated. T. entered upon the work with great energy, and although she met with much opposition, nevertheless succeeded in carrying out her reforms. In 1579, the Carmelites of the stricter observance established by T. were released from the jurisdiction of the old superiors, and united into a distinct association, with a separate head and a distinct organisation, which was approved in 1580 by Pope Gregory XIII. Under this new constitution, the association flourished and extended; and within the lifetime of T., no fewer than 17 convents of women and 16 of men accepted the reforms which she had originated. T. died at Alba, October 4, 1582, in her 68th year. She was canonised by Gregory XV. in 1621, her feast being fixed on the 15th October. She left a number of works, which have at all times maintained a high reputation among the spiritualists of her own church, and whose merits, in many respects, are acknowledged by non-Catholic writers. They consist of ascetical and mystical treatises, instructions in the conventual life, meditations, &c., besides a large number of letters, which possess remarkable literary merit, quite independent of their doctrinal character. Her works in the original Spanish fill two folio volumes, and they have been in the whole or in part translated into almost every European language. Her life occupies nearly an entire volume of the new continuation of the *Acta Sanctorum*; and several more popular biographies have been written in Spanish, French, Italian, German, and very recently in English by the Rev. Canon Dalton. See also *Leben der heil. Theresia*, von Dr Fr. Pösl (Regensburg, 1847).

TERLI'ZZI, a flourishing, well-built town of Italy, in the province of Bari, 20 miles south-east of Barletta, and 8 miles from the Adriatic. It contains a cathedral, a parish church, and three convents. The almond tree is extensively cultivated in the vicinity. Pop. about 20,000.

TERM, in Legal phrase, has several meanings, but that best known is when it denotes certain days of the year for calculating rent between landlord

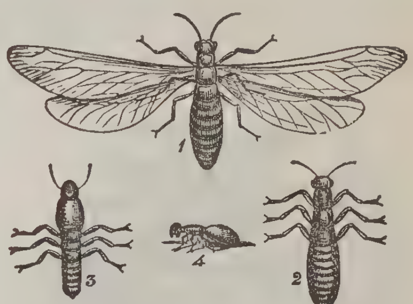
and tenant, and which have been adopted by immemorial usage, owing to the convenience of thus terminating the contract between the parties. In England and Ireland, the year is for this purpose divided into four quarters or terms. These are—Lady-day, March 25; Midsummer-day, June 24; Michaelmas-day, September 25; and Christmas-day, December 25. In Scotland, the terms as between landlord and tenant are divided into legal and conventional terms. There are two terms recognised by common law—viz., Whitsunday, May 15; and Martinmas, November 11; while other two conventional terms subdivide these—viz., Candlemas, February 2; and Lammas, August 1.—There is also a subdivision of the year into Law-terms (q. v.), adopted and sanctioned by statute for the purpose of the sittings of the law-courts. These are Hilary, Easter, Trinity, and Michaelmas terms.—There is a third and technical meaning of the word 'term,' when it means an estate for years in land.

TE'RMINI (anc. *Thermæ Himærenses*), a seaport town on the north coast of Sicily, 21 miles east-south-east of Palermo, at the mouth of the river Termini. It is built partly on a plateau (the summit of which is crowned by a castle—now a prison—of medieval construction), and partly on the slope and in the hollow beneath. T., with its noble background of towering hills, and its magnificent view of the Mediterranean, well deserves the title of *La Splendidissima*, bestowed on it by the Emperor Frederick II. Many of the inhabitants are engaged in fishing for tunny and anchovies. Pop. about 23,000.

The ancient *Thermæ* (of which T. is an Italian corruption) was founded 408 B.C., after the destruction of the Greek city of Himæra, and whence its name Himærenses. Whether it owed its origin to the Carthaginians themselves, or to the surviving citizens of Himæra, is doubtful; but it soon passed under the authority of the former, who here defeated the Romans with heavy loss (260 B.C.) during the first Punic war. After Sicily became a Roman province, Thermæ was treated with peculiar consideration by its new masters, and became a flourishing place. Relics of the ancient city, as the baths (which are still used), fragments of a theatre, and aqueduct, are still visible; and numerous inscriptions, statues, &c., are preserved in public and private collections.—See B. Romano's *Antichità Termitane* (Palermo, 1838).

TE'RMINUS, a Roman divinity, supposed to preside over public and private boundaries. Originally, he appears to have been the same as Jupiter himself, but gradually he was recognised as a separate and distinct god. Hardly any religious conception is more thoroughly characteristic of the Romans, that land-loving, law-reverencing people, than the conception of T., whose worship was practised down to a late period.

TE'RMITE, or WHITE ANT (*Termites*), a genus of insects of the order *Neuroptera*, and of the family *Termitidæ*, or *Termitinæ*. They live in great communities, chiefly in tropical countries, and are almost omnivorous, in the larva, and pupa, as well as in the perfect state. In their communities, there are five classes—males, females, workers, neuters, and soldiers. The workers, neuters, and soldiers seem all to be imperfectly developed females. The males and perfect females have four wings, which are long and nearly equal, and which are often suddenly cast off before the termination of their life; but the greater part of the community consists of workers, which are wingless. The 'soldiers' are larger than the neuters, and have very large mandibles, which they are always ready to use upon any assault. The antennæ of the genus *Termes* are long and thread-shaped, with about 20 joints; the eyes are small and prominent, and there are three *ocelli;* the abdomen has a pair of minute caudal appendages. Most of the white ants make their nests on the ground, but some of them among branches of trees, decayed or dry wood forming a principal article of their food. The species which make their nests on the ground make them conical, or turret-shaped, often 12 feet, and sometimes even 30 feet high, in groups, like a little village. The soil where the white ants have laboured is particularly good, and the South Africans take advantage of its excellent quality. The nest is divided internally into numerous chambers and galleries; there are generally two or three roofs within the dome-shaped interior, and the thick walls are perforated by passages leading to the nurseries and magazines of food. If a breach is made in the building, the soldiers appear, ready for defence. White ants are very useful in consuming every kind of decaying animal or vegetable matter



1 and 2, Perfect Termites; 3, Soldier; 4, Worker.

They even eat grass, and the snapping of multitudinous mandibles has been likened to the sound of a gentle wind among trees. They sometimes attack the wood-work of houses, and soon reduce the thickest timbers to a mere shell. Extraordinary and incredible stories are told of their attacking and devouring large animals, but it seems probable that they do so only when the animals are helpless from age or sickness. They come in vast hosts to any place where food is to be found, and are not easily driven off; multitudes pressing on, although previous multitudes have been destroyed. They gather great stores of corn into their nests, of which the natives of Africa often avail themselves. They are themselves also used as food in Africa, and are said to be delicate and pleasant. The abdomen of the pregnant female T. becomes dilated to an extraordinary degree, so as to exceed the rest of her body 1500 or 2000 times, and she is then about 1000 times heavier than the male insect. Her fecundity is prodigious; she is supposed to lay more than 31,000,000 of eggs in a year.

The Termites which live in trees construct nests of great size, like sugar-casks, of particles of gnawed wood, cemented by a kind of gluten, and so strongly attached to the branches as not to be shaken down even by violent storms. These species sometimes take up their abode in the roofs of houses, where they are very destructive to the wood-work.

Termes mordax and *T. atrox* are among the African ground-building species. *T. lucifugus* is found in the south of Europe, and has proved very destructive in the navy-yard of Rochefort, and elsewhere in the south of France. Sulphurous

gases and chlorine are forced into its galleries, without completely effecting its extirpation. *T. flavicollis* is very injurious to olive trees in Spain. *T. frontalis* extends as far north in the United States as Massachusetts, and does mischief in vineries, not only attacking dead wood, but the roots of living vines. No true species of *Termes* is found in Britain, but some of the *Termitidæ* are British insects. One of them is *Psocus pulsatorius*, one of the insects which emit a sound like the ticking of a watch in houses. The species of the genus *Psocus* are very small, active insects, living beneath the bark of trees, in wood, straw, &c. Some of them are often found among books and in collections of natural history.

In books of travels, the termites are often called ants, their habits being similar, although they belong to a different order of insects.

TERN (*Sterna*), a genus of birds of the Gull family (*Laridæ*), by some made the type of a distinct family (*Sternidæ*); having the bill as long as the head, or longer, nearly straight, compressed, slender, tapering; the wings long and pointed; the tail long and forked. The plumage is very full. From their forked tail, manner of flight, and small size, the terns are often called sea-swallows. They are

Common Tern (*Sterna hirundo*).

incessantly on the wing, skimming the surface of the water, and catching small fishes and other small animals from it. The species are numerous, and are found in almost all parts of the world. Some of them are of very wide geographic distribution. Many are birds of passage. Thus, all which occur on the British coasts, and in other northern parts of the world, are mere summer visitants. The COMMON T. (*S. hirundo*) is abundant on the more southern shores of Britain, but rarer in the north. It is found also on the coasts of Europe, Asia, and Africa, from the Arctic Circle to the farthest south; but there is some doubt if its range extends to America, where a very similar species, WILSON'S T. (*S. Wilsoni*), was long mistaken for it.

TERNA'TÉ. See MOLUCCAS.

TE'RNI (anc. *Interamna*), a town of Central Italy, on the right bank of the Nera (anc. *Nar*), a little below its confluence with the Velino, 49 miles north-north-east of Rome. It is encircled by a wall, with towers and five gates, is well-built, gives name to an archbishopric, and possesses a cathedral, several fine palaces and churches, a hospital, theatre, and various monuments of antiquity, as the ruins of an amphitheatre, temples, and baths—none of which, however, are of much importance. T. manufactures silk and woollen fabrics. Pop. about 10,000. About two miles from the town is the famous cataract of Velino, 500 feet high, celebrated by Byron in his *Childe Harold*.

Ancient *Interamna*, according to classic tradition, was founded only 80 years after Rome, but we have no knowledge of its history until it ceased to be an Umbrian, and became a Roman city. About the time of Marius and Sulla, it was (according to Florus) one of the *florentissima Italiæ municipia*, but at no period did it occupy a very prominent position. Its chief claim to notice arises from its being regarded (by some) as the birthplace of the historian Tacitus, and of his descendant, the emperor of the same name.

TERNSTRŒMIA'CEÆ, a natural order of exogenous plants, allied to *Guttiferæ*, and consisting of trees and shrubs, natives of warm and temperate countries. About 150 species are known. They are most abundant in South America; a few are found in North America; some in India, China, and other parts of the East; only one African species is known; and Europe produces none. The leaves are alternate, leathery, in many species evergreen, generally undivided, sometimes dotted. The flowers are on axillary or terminal stalks, generally white, sometimes pink or red; with 5—7 concave, leathery, deciduous sepals, and 5—9 petals, which are often combined at the base; many hypogynous stamens, which are either free or variously combined; 2—7 filiform styles, more or less combined; the fruit a 2—7-celled capsule, either opening by valves, or leathery and indehiscent, the seeds large, few, and attached to the axis, the cotyledons very large, and often containing much oil. This order is very important as containing the Tea-shrubs. It is also interesting because of the great beauty both of the foliage and flowers of many of the species, of which the genus *Camellia* affords the best-known examples. See TEA, CAMELLIA, and GORDONIA.

TERPSI'CHORÉ (Gr., delighting in the dance), one of the nine Muses (q. v.), presided over choral song and dancing.

Statue of Terpsichore.

TERRACI'NA (anc. *Tarracina*), a town of Italy, in Velletri, formerly a delegation of the Papal States, on the coast at the south-east extremity of the Pontine Marshes, near the mouths of the Ufente and Amaseno. It is the seat of a bishop, possesses a cathedral (built on the ruins of a heathen temple), a square with a handsome fountain, a palace of Pius VI., and, on the summit of a precipice overlooking the town, the ruins of a palace of Theodoric, king of the Goths. The harbour, a naval station of the Romans, is now filled up. Pop. 4600.

Tarracina was originally a Volscian town, and was called by the Volscians *Anxur*, a name which is often applied to it by the Latin poets. It fell into the hands of the Romans 400 B. C., became the seat of a Roman colony 329 B. C., and as long as the Republic and Empire lasted, was a flourishing and important city. So closely do the mountains here approach the sea, that there was scarcely room for the celebrated 'Appian Way;' hence the importance of T. as a military position. Numerous ruins of the ancient town are extant.

TERRA-CO'TTA, an Italian term signifying *baked clay*. It is applied chiefly, if not altogether, to

manufactures of brick-earth used for ornamental purposes, especially those used architecturally. Formerly, it was not uncommon in Britain, particularly about the beginning of the 18th c.; but after the reign of Queen Anne, it was discontinued, and was scarcely ever used until within the last ten years. A complete revival has now taken place, and this material has been applied with admirable effect in some of the buildings lately erected, especially the South Kensington Museum, and the Charing Cross Railway Station Hotel.

TE'RRA DEL FUE'GO, more correctly, Tierra del Fuego (q. v.).

TE'RRA DI LAVO'RO, or CASERTA, a maritime province of Southern Italy, bounded on the N.-W. by the former Papal States. Area, 2500 square miles; pop., according to the census of 1881, 714,487. This is the famous *Campania Felix* of the ancients. Pliny extols its beauty and its fine situation. Florus calls it the finest country in the world. In ancient times, it was inhabited by the Ausonii, the Osci, and later by the Campani. The finest part of Campania has been separated from it, and is that fertile tract of country which surrounds the Gulf of Naples like an amphitheatre; another part has been added to the province of Molise. T. di L. is watered by two rivers, the Liris or Garigliano and the Volturno. Towards the east, it is broken up by the Apennines, and its beautiful ranges of hills are clothed with vine and olive yards, and studded with country-seats. It produces corn, strong wines, oil, fruits, and silk. Its seaport towns are populous and busy, although here and there the sea-board is interrupted by marshes. The climate is very mild in winter, and extremely hot in summer.

TE'RRA DI SIE'NNA. See BURNT SIENNA.

TERRA-FI'RMA, a term frequently employed to denote continental land as distinguished from islands. But it was at one time more specially applied—1st, to all the mainland of Italy which acknowledged the supremacy of Venice—viz., to the duchy of Venice, Venetian Lombardy, the March of Treviso, the duchy of Friuli and Istria; 2d, to that extensive tract of South America, bounded by the Pacific Ocean, Peru, the silvas of the Amazon, the Atlantic Ocean, and the Isthmus of Panama, which mostly belonged to the Spaniards during the last century. In a still more restricted sense, the term was applied by the Spaniards to the Isthmus of Panama itself. Colloquially, the phrase *terra-firma* is applied (but erroneously) to land as distinguished from water.

TERRA JAPO'NICA. See CATECHU.

TERRANO'VA, a seaport town on the south coast of Sicily, province of Caltanisetta, on the right bank of the Omonimo, 18 miles east from Alicata. Pop. about 20,000. There is no regular port, but the town carries on a good trade in fruit, corn, pulse, sulphur, soda, and above all, in cotton, large quantities of which are grown in the vicinity. A kind of coarse cloth is manufactured for home consumption. T. is believed to occupy the site of the ancient Gela (q. v.). The town now standing was built by Frederick II. in the 12th century. In its neighbourhood is the village of Mazarino, from which the famous cardinal took his name.

TE'RRAPIN, the popular name of many species of fresh-water tortoises, of the family *Emydidæ* (see EMYS), natives of tropical and the warmer temperate countries. The neck can be wholly retracted within the shell; the head is flat, and the jaws prolonged into a beak. They feed partly on vegetable food, but also devour fish, reptiles, and other aquatic animals. They swim very well, and even on land move with much greater swiftness than land-tortoises. Their flesh is generally much esteemed.—Very many species are natives of North America.

TERRE HAUTE, a city of Indiana, U. S., on the east bank of the Wabash, 73 miles west-south-west of Indianapolis. The public buildings include the State Normal School, Providence Hospital, industrial school, a fine opera-house, 7 banks, 7 public-school edifices, Roman Catholic convent and schools, 18 churches, &c. It has 3 daily and 5 weekly papers, 2 public libraries, and abundant supplies of bituminous coal. It is the terminus of 6 important railways, connecting it with all the principal cities of the West. Pop. (1860) 8594; (1870) 16,103; (1880) 26,042.

TERRE-PLEIN, in Fortification, is the flat surface of the rampart, on the front portion of which the parapet and banquette are formed, and of which the rear slopes down to the general level of the enclosure.

TERRE'STRIAL MAGNETISM. In the article MAGNETISM, it is shewn that the earth itself is to be considered as a great magnet; and in the present article it is proposed to exhibit the chief results of observation on the earth's magnetism as seen in its action on artificial magnets. That action is simply *directive;* that is, it determines the way in which the magnet shall point, but has no tendency to translate or move it bodily. Terrestrial magnetism acts differently at different places; what are called the *magnetic elements* of a place, are the direction of the needle in regard to the points of the horizon (*variation* or *declination*), its direction in regard to the vertical (*inclination* or *dip*), and the force that keeps it in these positions (*intensity*). For the first two elements, see DECLINATION-NEEDLE and DIPPING-NEEDLE. The element of intensity is more difficult to determine. The relative horizontal intensity is measured by the number of oscillations that a needle, of unit size and strength, when disturbed makes in a given time, the intensities of two places being as the squares of the oscillations. The total intensity is got by dividing the horizontal intensity by the cosine of the angle of dip. Gauss has succeeded in reducing this measurement from a relative to an absolute standard.

Magnetic Charts.—The magnetic elements have been ascertained with great care at different portions of the earth's surface. The knowledge thus obtained has been embodied in magnetic charts, in which the points at which the declination is the same are joined by lines, and similarly those where the dip and intensity are alike. The lines of equal declination are called isogonic lines; those of equal dip, isoclinic; and those of equal intensity, isodynamic lines. As the magnetism of the earth is subject to a slow secular variation, such charts are only true for the time of observation. The chart, fig. 1, was drawn up by Colonel Sabine for the year 1840, and gives an approximate view of the lines of equal declination for that year. The change since 1840 has been small, so that an isogonic chart for the present time would differ but slightly from it. The chart sufficiently explains itself. Attention may however, be given to one or two points. The declination is marked on each line. Thus, the line passing through England, for instance, is marked 25°, and that passing north-west of the British Islands, 30°. At places under those lines, the needle points to a north 25° and 30° west of the true north. On the space intervening between these lines, including Scotland and Ireland, a correction, varying from 0° to 5°, must be made according as the station lies more towards the one line than the other. The westerly line of no declination passing northward

cuts off the eastern corner of South America, proceeds to North America, which it enters at North Carolina, traverses the continent by Lakes Erie and Huron and the west of Hudson's Bay, and ends in the north of the continent at Boothia. The easterly line of no declination passing southward enters Europe in the north of Russia, crosses the White Sea, the east of Russia, of the Caspian Sea, of Persia, and the Arabian Sea; then turns eastward, and cutting off the west of Australia, passes southward. The space included between those two lines, and which in the chart is left untinted, constitutes, so to speak, the hemisphere of westerly declination. It includes the east of the two Americas, the Atlantic Ocean, the whole of Europe and Africa, and the west of Asia and Australia. The rest of the earth, which in the chart is tinted, has an easterly declination. There is an elliptic space in Eastern Asia which is

Fig. 1.

left white, having a westerly variation, and forms an exceptional region in the eastern magnetic hemisphere.

It will be seen that the lines converge in the north of North America, and in the south of Australia. So far as experience goes, and so far as the most matter-of-fact theory (Gauss's) teaches, the convergence in both cases is to a point. The point in North America is the *north magnetic pole*, and that south of Australia is the *south magnetic pole*. At these points, then, all isogonic lines converge, and a compass-needle lies indifferently in any position.

The isogonic lines, as seen from the chart, form a somewhat complicated system. This arises from the fact, that we refer the indications of the needle to the geographical poles, which are, so far as we know, arbitrary or extraneous as regards terrestrial magnetism. Duperrey, by drawing what he calls *magnetic meridians and parallels*, draws a system of lines which have much the same conformation with regard to the magnetic poles that the meridians and parallels of latitude have to the geographical poles. A magnetic meridian, according to Duperrey, is the line that would be described by a person setting out, say from the south magnetic pole, and travelling always in the direction of the magnetic north till he reached the north magnetic pole. The magnetic parallels are lines drawn at right angles to the magnetic meridians.

In fig. 2, the isoclinic lines, by the same author and for the same epoch, are given. In the upper part of the chart, which is left white, the north end of the needle dips; and in the lower part, which is tinted, the south end of the needle dips. The amount of dip is marked on each line. Thus, the line passing through the centre of England is marked 70°. A dipping-needle, at any place cut by the line, is inclined 70° to the horizon. The line 75° passes to the north of the British Isles. In Ireland and Scotland, therefore, the dipping-needle has an inclination greater than 70°, and less than 75°. The line marked 0° is the line of no dip; at any station on it the dipping-needle is horizontal. This line is called the *magnetic equator*. It will be seen that it is not coincident with the geographical equator; it is not even a great circle of the earth, but is an irregular curve cutting the equator in two points, one near the west coast of Africa, and the other in the middle of the Pacific Ocean. The points on the earth's surface where the dipping-needle stands vertical, and where, in consequence, as before mentioned, the compass-needle lies in any direction, are called the magnetic poles. The north magnetic pole was found in Boothia Felix by Captain Ross at 70° 5′ N. lat., and 263° 14′ E. long. According to Gauss's calculation, it should have been at the time (1831) some 3′ north of this point. From observations made at Hobart Town, the nearest station to it, the south magnetic pole should lie 66° S. lat. and 146° E. long. These points are not diametrically opposite each other, as the geographical poles. If the lines of equal dip were drawn on a globe, they would form round the magnetic poles a system of irregular circles, somewhat resembling

that of the parallels of latitude round the poles of the earth.

We do not add an isodynamic chart, as it would take up too much space. Colonel Sabine's Dynamical Chart, along with the isogonic and isoclinic charts, will be found fully engraved and explained in Johnston's *Physical Atlas* (new edition). From this chart we learn that the magnetic intensity is least in the vicinity of the magnetic equator, and increases as we approach the magnetic poles. The lines of equal intensity, though running much in the same direction as the lines of equal dip, are neither coincident nor parallel with them. The line of least intensity, itself not an isodynamic line, runs nearly parallel to the magnetic equator, but lies, except in the western half of the Pacific, a few degrees to the south of it. We thus learn that the changes in direction and intensity do not march together. We should fancy that at that point or points on the earth's surface where the dipping-needle stood erect, we should be nearest to the centre of free magnetic energy, and that there the force would be greatest; but this is not the case. The point in North America where the intensity is greatest, is situated to the west of Hudson's Bay, some 18° south of the north magnetic pole. But this is not the only point of maximum force in the north magnetic hemisphere. There is another, which was found by Hansteen in 1828 in Northern Siberia, about the longitude 120°. This maximum point is weaker than the American in the proportion of 100 to 107 (Sabine). According to Gauss, there can only be one maximum point in the southern hemisphere, which is stronger than either of the other two. It lies north-east of the south magnetic pole, and its intensity is 137 (Gauss) compared with 107, that of the principal northern centre. At none of those points does the dipping-needle stand erect. This want of coincidence of the points of vertical dip and of maximum intensity has led to some confusion in the use of the term magnetic pole; some writers meaning by it a point of vertical dip, and others a point of maximum intensity. In adopting the former definition, we are only adhering to the popular meaning of the word, and to the opinion of Gauss, perhaps the greatest authority on the subject. Some of the best English authorities, however, attach to it the latter meaning.

Although the total intensity increases as we go northward or southward from the line of least intensity, the horizontal intensity diminishes. This arises from the fact, that the greater the dip the less the horizontal intensity. Hence the compass-needle,

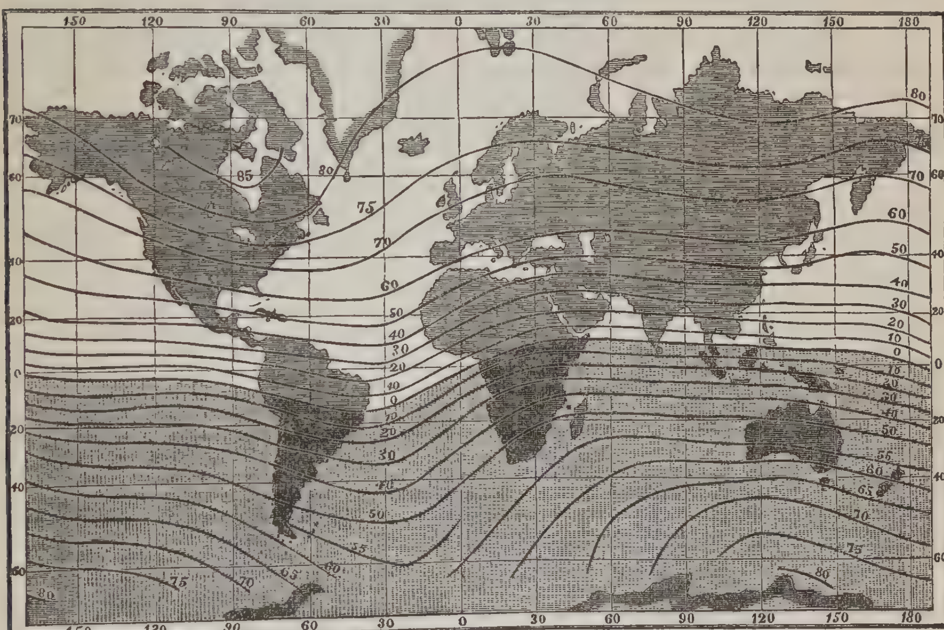


Fig. 2.

which is affected alone by the horizontal intensity, oscillates more sluggishly as we leave the line of least intensity. A dipping-needle, for instance, oscillates faster at London than at Calcutta, because the total intensity which affects it is greater at London than at Calcutta; but with a compass-needle it is the reverse, from the horizontal intensity being greater at the latter than at the former station.

Variations of the Needle.—The magnetic elements do not remain constant in the same place, but are subject to continual though small variations. These are regular and irregular. Under regular variations are included *secular*, *annual*, and *diurnal* variations. The secular variations take centuries for their completion. The following list of the declination and dip at London in different years will give an idea of the secular variations for these elements:

Year.	Declination.
1576, . .	11° 15′ easterly.
1657—1662,	0° 0′ no declination.
1760, .	19° 30′ westerly.
1815, . .	24° 27′ 18″ westerly. Maximum.
1850, .	22° 29′ 30″ westerly.
1865, Jan. 1, at Kew,	21° 6′

Year.	Declination.
1720, . .	74° 42′
1780, .	72° 8′
1800, . .	70° 35′
1830, .	69° 38′
1850, . .	68° 48′
1865, Jan. 1, at Kew,	68° 9′

At present, the annual decrease of declination at Kew is 8′. At this rate it would take rather more than 84 years for the compass-needle to shift through a whole point. From the observations of

the dip, we find that it has been gradually decreasing for the last 150 years. The annual decrease of dip is at present about 2′·6. The time during which observations have been taken of the declination and dip is far from comprehending a cycle of change in either, and it is a mere matter of speculation how long that may take. The magnetic history of London does not apply to other places; each place, so far as has been ascertained, having a magnetic history of its own. Thus, in Paris, the time of no declination was 1669; and of maximum declination, 1814; the latter amounting to 22° 34′ W. Every place, according to Barlow, appears to have its own magnetic pole and equator. Magnetic intensity has been observed for so short a time, that little as yet is known of its secular variation. At present, the horizontal intensity is increasing in Europe, but that may arise partly from decrease of dip.

The magnetic elements are also subject to changes, which have a yearly and a daily period. In describing these shortly, we shall limit ourselves to the changes affecting declination, as these are of most general interest. The following are the chief particulars of the *annual variation* of declination given by Cassini: From April to July, or from the vernal equinox to the summer solstice, the western declination decreases. From the summer solstice to the vernal equinox, that is, during the other nine months of the year, the declination increases, the needle turning to the west. Its position in May and in October is nearly the same; so that in the winter months, from October to April, the westerly motion is slow. The range of the annual variation at Kew is 58″·85.

The mean *diurnal variation* for Kew is shewn in fig. 3. The irregular line indicates the course of the north end of the needle. A rise of this line indicates a change of the north end to the east; a fall, a change to the west. The interval between two horizontal lines corresponds to a deflection of the needle 1′ to the east, and a fall 1′ to the west. The line marked ° is the magnetic meridian, or the mean daily position of the needle. The interval between two upright lines corresponds to an hour. The course begins at twelve at night, and ends at twelve the following night. At twelve at night, the magnet is 1½′ east of the mean position, and continues nearly in the same position, with only a slight westerly deviation, till 15 hours (three in the morning), when it veers eastward. At 20 hours (eight in the morning), it reaches its furthest east point. From eight in the morning till one in the afternoon, it makes a sweep of 10′ towards the west, and then stands about 6′ to the west of the mean. After one, it goes westward till midnight, when it again begins the same course. The needle stands in its mean position a little after ten in the morning, and a little before seven in the evening. The course here described is the course for the year. But the diurnal range is different in different months. In May, for instance, the average range between the extreme points is 12′, which is the maximum range for the year; and in December, when it is a minimum, it is only 5′ 28″. The diurnal changes here described for Kew are much the same all over the north magnetic hemisphere. The amount, however, is different. Near the magnetic equator the diurnal variation is little or nothing, and it increases as we go northward. Captain Duperrey states that at or near the magnetic equator, the north point of the needle in the morning shifts slightly east or west of the mean, according as the sun passes south or north of the station. In the southern magnetic hemisphere, the daily motions of the needle take place much in the same way as in the northern hemisphere, only the south pole takes the place of the north pole, and the direction of the deflections is reversed. The correspondence, and at the same time opposition, of the southern hemisphere is also shewn from the time of maximum and minimum range. When the sun is in the northern signs of the zodiac, the range is a maximum in the northern, and a minimum in the southern hemisphere; and when the sun is in the southern signs, the reverse takes place. The diurnal variation is so small, that the ordinary compass-needle is not delicate enough to shew it.

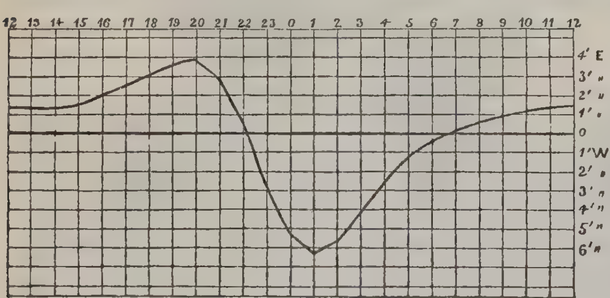

Fig. 3.

The *irregular variations* are those which break in upon the regular march of the diurnal variation, without in the main altering it. Instead, for instance, of the needle steadily going westward from 8 A.M. to 1 P.M., as shewn in fig. 3, it makes, when affected by irregular variation, deflections eastward as well as westward, although it in the main moves westward; so that the line between these hours, instead of being comparatively straight, would be an irregular zigzag. These disturbances of the mean course are sometimes considerable, amounting even to one or two degrees in extreme cases. On some days, the mean diurnal course is much disturbed, on others, very little; but it is never quite free from them. It has been found that places of the same longitude have similar disturbances at the same time; that those on opposite sides of the globe, or differing by 180° of longitude, have disturbances equal in amount, but opposite in direction; and that those situated 90° west or east of the disturbed regions, have little or no disturbance. The appearance of auroras is invariably accompanied by magnetic irregularities, and their effect extends far beyond the regions where they are visible. Earthquakes and volcanic eruptions have also a marked effect in this way. Humboldt gave the name of *Magnetic Storms* to these irregular disturbances. Sabine has found that the frequency of magnetic storms is greatest every ten years, at the same time that the spots on the sun are most numerous.

1. *Theories of Terrestrial Magnetism.*—The earliest theory was that suggested by Gilbert, in which it is supposed that a magnet in the middle of the earth extends from one magnetic pole to the other. On this supposition, the general phenomena of terrestrial magnetism may be accounted for—a needle, both by declination and dip, must point to the poles. This must always remain, from its simplicity, the popular theory on the subject. In consistency with his theory, Gilbert considered the north pole of the magnet to be a south pole, as he

took the north pole of the earth for his standard north pole. If this theory were correct, the magnetic equator would be a great circle of the earth, and the magnetic poles would be 90° from it, which is far from the case. It is only a rough approximation to a just theory.

Halley endeavoured to supplement Gilbert's theory, by supposing two magnets of unequal strength crossing each other at the earth's centre to be the cause of terrestrial magnetism. The theory of the two magnets or four poles was ably defended by Hansteen.

Barlow considered that the earth acted on the needle as if currents of electricity traversed it from east to west. He imitated its action by wrapping a wire in parallel coils round a wooden globe, and causing a galvanic current to pass through it. Each turn of the wire represented a magnetic parallel, and the two ends of the coil the magnetic poles; and to complete the analogy, the globe was movable on an axis, which stood in the same relation to the ends of the coil as the astronomical to the magnetic poles of the earth. When a small needle was placed on the globe, its declination and dip bore a striking resemblance to those of a needle similarly situated on the earth's surface. The objection to this theory is the difficulty of accounting for the origin of such currents in the earth. To meet this, some suppose the earth to be a huge thermo-electric pile; as the heat of the sun falls on one side of it, currents are there generated which travel round the globe. But how, again, it may be asked, are the conditions of thermo-electricity implemented by the materials of the earth? This question still remains to be answered. The close connection between temperature and magnetism is shewn by the diurnal variation of declination, the epochs of which closely correspond with those of the daily temperature, and by the fact, that the isodynamic and isothermal lines manifest a marked correspondence. Sir David Brewster has also shewn that there are two centres of maximum cold in the northern hemisphere, which are situated near to the two intensity poles.

Gauss did not start from any simple supposition of one or two magnets giving rise to the magnetism of the earth, nor did he assert or deny its electric origin. Considering the whole earth as magnetic, he aimed at determining how it must act as a whole at the different points on its surface. In order to make the equations he obtained theoretically in this attempt express the distribution on the earth, the magnetic elements of eight stations at a sufficient distance from each other on the earth's surface had to be ascertained and substituted in these equations. This done, from the longitude and latitude of any station he considered himself prepared to deduce its magnetic elements. The magnetic charts which he sketched, though founded on the imperfect observations to which he had access, are singularly in keeping with fact, and go far to establish the correctness of his reasonings.

The secular variations are as yet wholly unaccounted for. The cause of the diurnal variation is universally attributed to the sun. Secchi, who carefully studied the diurnal variation of the needle, considers that the sun, so far as they are concerned, acts upon the earth as a powerful magnet at a distance.

Historical Sketch.—The discovery of the change in declination at different places is generally attributed to Columbus, and was one of the many important observations of his memorable voyage across the Atlantic. Robert Norman, an instrument-maker in London, first discovered the dip of the needle in 1576. He was led to it by finding that needles nicely balanced before magnetisation had to be slightly loaded on the south end, to keep them horizontal after being magnetised. Gilbert (1600) gave the first theory of terrestrial magnetism, viz., that of the single magnet. Halley, the astronomer-royal, published his theory of the four poles in 1683. In 1688 and 1689, at the expense of government, he made two magnetic voyages, the results of which he embodied in his charts of the lines of equal declination, published in 1701, which were the first magnetic charts ever published. In 1722, the diurnal variation was discovered by Graham, the celebrated instrument-maker of London. The first inclination chart was published by Wilke at Stockholm, 1768. Humboldt inaugurated the present system of careful observations of terrestrial magnetism by taking comparative measurements of the magnetic elements at Peru and Paris (1799—1803). Hansteen's work on the *Magnetism of the Earth* was published at Christiania, 1817; in 1826 he published the first isodynamic charts. Barlow (1831) suggested the electric origin of terrestrial magnetism. In 1831, Captain Ross came upon the north magnetic pole. In 1835, stations were established throughout Europe, and the observations were published by Gauss and Weber, 1836. Gauss (1833—1840) perfected his theory. In 1837, Colonel Sabine published an isodynamic chart of the whole globe. Observations were made (1840—1854) at stations throughout the British Empire by British officers, under the direction of Colonel Sabine.

TERRESTRIAL TEMPERATURE. The distribution of heat over the globe is represented by isothermal lines, or lines drawn through all places having the same mean temperature. The mean annual temperature is shewn by the lines in fig. 1, and the warmest and coldest months in fig. 2, the dotted lines shewing the mean temperature for January, and the solid lines the temperature for July.

The part of the globe having the highest mean annual temperature forms an irregularly shaped belt, lying along the equator, and comprised between the north and the south isothermals of 80°. On either side of this warm belt the temperature diminishes towards the poles; and the lines shewing successively this diminution are, speaking in a very loose sense, arranged parallel to the equator, thus shewing the all-predominating influence of the sun as the source of terrestrial heat. The coldest portion of the earth's surface is a small oval-shaped patch near to but not surrounding the north pole, its mean temperature being −4°. Its narrowest diameter lies north and south, nearly touching the pole on the one side, and extending on the other as far south as 72°·30 N. lat. in 130° W. long. Part of it is seen in the diagram. On looking at the isothermal of 0°, one might be led to suppose that there are two centres of greatest cold, one north of Siberia, and the other north of British America. Such, however, is not the case—the apparent double centre of greatest cold being solely due to the isothermals being drawn on Mercator's projection of the earth; for if an isothermal map be drawn on a polar projection, the lines of mean annual temperature enclose one connected space of greatest cold, and not two such spaces, as is not unfrequently stated.

While the decrease of temperature in advancing towards the poles corresponds in a general way to what may be called the solar climate, there are deviations brought about by disturbing causes too important to be overlooked. These disturbing causes are (1) the currents of the sea; (2) the prevailing winds; and (3) large surfaces of water which are frozen during part of the year.

The influence of an oceanic current depends on

the temperature of the place it leaves and the place at which it arrives. Hence the great equatorial current, flowing from east to west, does not require to be considered here, because the heat remains the same throughout its course; but only those currents which convey the waters of the sea to higher or to lower latitudes. Of these, the most marked and important is the Gulf Stream in the North Atlantic, which, by conveying warm water to the arctic regions, pushes the isothermals many degrees to the northward. There is a similar, though much feebler, current passing from the North Pacific to the Arctic Sea through Behring's Strait, and there, accordingly, the isothermals are pushed a little to the northward. In the southern hemisphere, there are two currents, one discovered by Humboldt, passing from the Antarctic Ocean northward by the coast of Peru as far as Lima; the other flowing from the Cape of Good Hope northward along the west coast of Africa: these currents, flowing from colder to warmer latitudes, lower the temperature, and thus drive the isothermals towards the equator. Again, the great equatorial current, after impinging on the east coast of Africa, turns southward, and by the warmth it imparts, pushes the isothermals into higher latitudes. For the same reason, the current flowing southward past the coast of Brazil, raises the temperature in the east of that country. The influence of these great currents is more distinctly marked in the forms of the isothermals for January and July. Thus, in January, when the relative excess of the temperature of the Gulf Stream is greatest, the isothermals are driven very far to the north; and similarly in the southern hemisphere, the currents from the Antarctic Ocean being coldest in July, the isothermals are deflected more towards the equator during that month. The most remarkable lowering of the isothermals occurs in Labrador

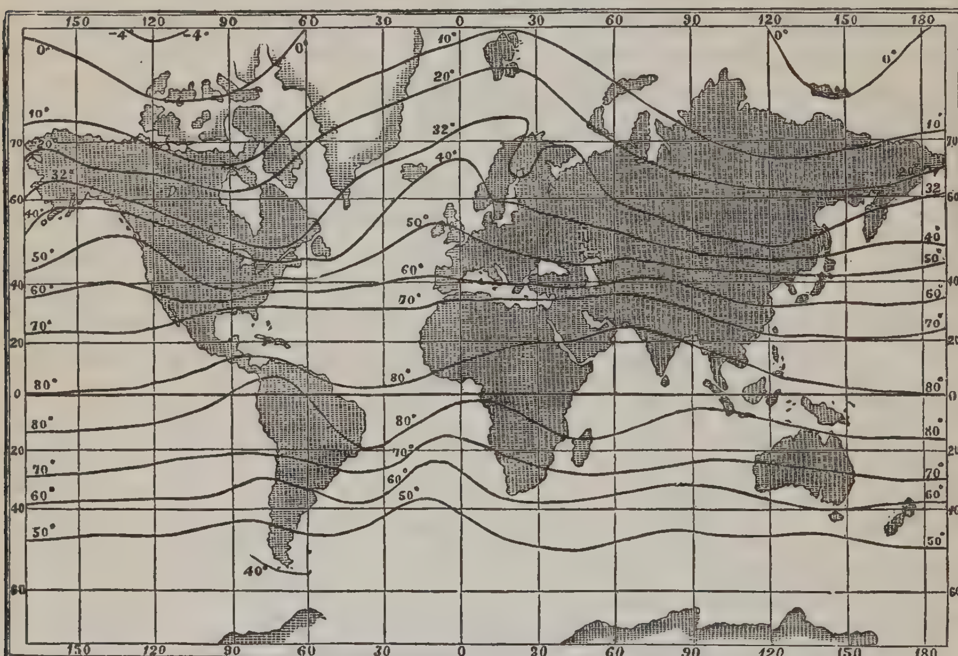

Fig. 1.

and Newfoundland during May and June, and is caused by the icebergs which then descend on these coasts from Davis' Strait.

Since winds bring with them the temperature of the regions they have crossed, the equatorial current is a warm wind, and the polar a cold wind; also winds arriving from the ocean are not subject to such variation of temperature during the year as winds from a continent. As an atmosphere loaded with vapour obstructs both solar and nocturnal radiation, it follows that moist winds are accompanied with a warm temperature in winter, and a cool temperature in summer; and dry winds with cold winters and hot summers. The direction of mountain-ranges is also an important element to be taken into account in estimating the influence of winds on temperature. These considerations explain the position of the isothermals in the north temperate zone, where the prevailing wind is the south-west or anti-trade (see WINDS). In January, the western parts of each continent enjoy a comparatively high temperature, from their proximity to the ocean, whose high temperature the winds waft thither; and they are further protected from extreme cold by their moist atmosphere and clouded skies. But in the interior of the continents it is otherwise; for the winds getting colder as they advance, and being deprived of their moisture as they cross the mountains in the west, the soil is exposed to the full effects of radiation during the long winter nights, and as a consequence, the temperature rapidly falls. In the centre of Siberia, the January temperature falls to $-40°$, which is $9°$ colder than the coldest part of the American continent; and this centre of greatest cold lies near the eastern part of the continent of Asia. On the other hand, in July, the interior of continents is much warmer than their western parts. Hence the interior and eastern parts of Asia and America are characterised by extreme climates, and the western parts by equable climates. Thus, at Yakutsk, in Siberia, the July temperature is $62°·2$, and the January $-43°·8$, the difference

being 106°·0; whilst at Dublin these are respectively 60°·8 and 38°·5, the difference being only 22°·3. This constitutes the most important distinction of climates, both as respects vegetable and animal life. On man especially the effect is very great—the severity of the strain of extreme climates on his system being shewn by the rapidly-increasing death-rate as the difference between the July and January temperature increases.

The great fresh-water lakes of North America—Lakes Superior, Huron, Erie, Michigan, Ontario, Bear Lake, &c.—exercise an important influence on

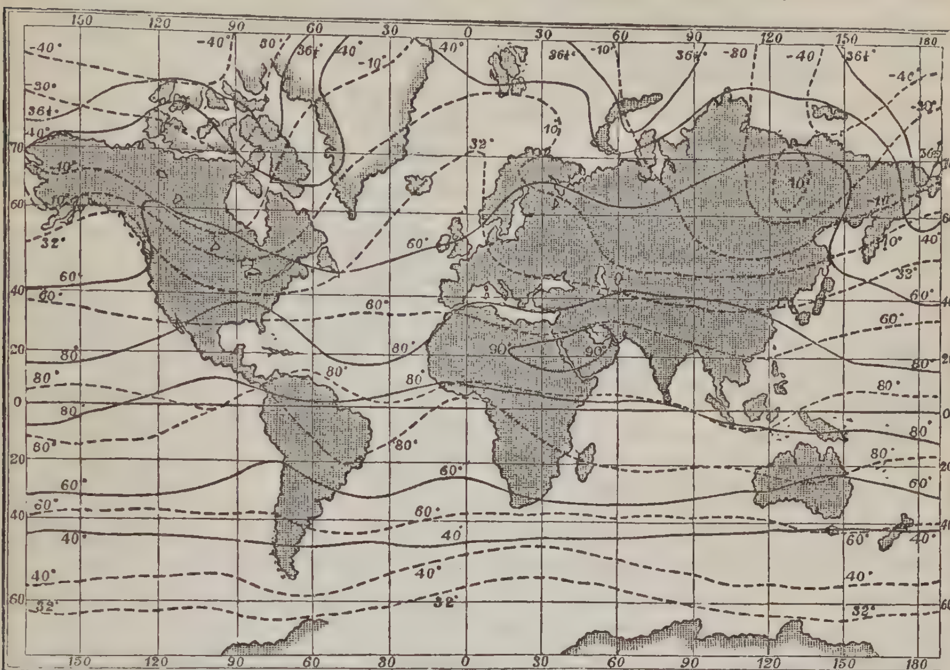

Fig. 2.

the climate of the central parts of North America, for in winter, America, with its frozen lakes, is a truly unbroken continental mass, and its winter climate is therefore continental; whereas in summer its numerous large sheets of fresh water communicate to it many of the features of an insular summer climate.

The whole effect of the disturbing causes is seen at once, if we compare the observed temperature of a place with its normal temperature, that is, the temperature due to it in respect of its latitude. In the northern hemisphere, in January, the sea and the western parts of the continents are in excess of their normal temperature; elsewhere, there is a deficiency. There are two centres of excess, one to the north-east of Iceland, amounting to 41°; the other in Russian America, amounting only to 18°; and two centres where the temperature is deficient, one at Irkutsk, amounting to 41°; and the other west of Hudson's Bay, amounting to 27°. In July, the United States, Europe, Asia, the Indian Ocean, the north of Africa, and the extreme north of South America, have their temperature in excess, while elsewhere it is deficient. The centres of excess are, north of Siberia, 13°·5; Red Sea, 11°·0; and north-west of the United States, 4°·5: and the centres where the temperature is deficient are, the entrance to Hudson's Bay, 11°·0; and the Aleutian Islands, 11°·0.

TE'RRIER, a small kind of dog, remarkable for sagacity, vivacity, courage, and eagerness in the pursuit of 'vermin,' which it readily follows into burrows; whence apparently the name T., from Lat. *terra*, the earth. The courage of the T., however, is such that it will readily attack animals much larger than itself; and it has been observed in India that terriers will fearlessly rush at the largest carnivora, when even the bull-dog hesitates. Terriers are of great use for killing

Scotch and English Terriers.

rats in places much infested by them. They are also used for compelling the fox to leave his retreat; and a large variety called the *Saufinder*—that is, Boar-seeker—is employed in Germany to rouse the fiercest beasts of the forest from their

lairs. The varieties of T. are numerous. In Britain, two are particularly prevalent, known as Scotch and English terriers—the former with long, rough, wiry hair, with which even the face is much covered; the latter with smooth, short hair. The ears are either erect and pointed, or have pendent tips. The Skye T. is a breed of Scotch T., peculiarly prized. If any kind of dog may be regarded as truly indigenous in Britain, it is the T.; but there is no certainty that it was not imported by the first inhabitants. Dogs very similar have existed in the north of Europe in a domesticated state from remote antiquity. The BULL T. is probably a cross between the T. and the Bull-dog (q. v.).

TERSCHELLING, one of the chain of islands to the north of Holland, lies in 53° 24′ N. lat., the principal villages being Oosterschelling, Westerschelling, and Midsland. It consists of fertile arable and meadow lands, is protected on the south by large dykes, and in other parts by downs, which are carefully preserved. Area about 45 sq. miles. Pop. 3128. There is a good haven, a shipbuilding-yard, a woollen dyework, &c. The old church of the hamlet of Stroe (Strū) is supposed to be a former heathen temple. T. was the birthplace of William Barentz, the celebrated Arctic explorer. See NORTH-EAST PASSAGE.

TE'RTIAN FEVER. See AGUE.

TE'RTIARY (Lat. *Tertiarius*, one of the third rank), a name given by church writers to a class in the Roman Catholic Church, who, without entering into the seclusion of a monastery, aspire to practise in ordinary life all the substantial obligations of the scheme of virtue supposed to be laid down in the Gospel. Whatever earlier traces of this institution may be observable, there is no dispute that it was under St Francis and the mendicant orders generally that the institute of T. reached its full development. The rules of the institution of T., such as they have since substantially been maintained, were made public in 1221. The associates must, of course, all be members of the church; and it is moreover required that all shall be of good repute and blameless life. The intending members must restore all ill-gotten goods, must renounce all evil practices, and abandon all feuds and enmities with their neighbours. Wives cannot be received without the consent of their husbands. The obligation of T. once accepted, is irrevocable, unless the party should be released, or should enter into a more strict religious order. The members are required to renounce luxury of life, profane exercises and amusements, costly or unseemly dress, and the use of arms, except in the necessity of self-defence. They must frequent the sacraments; hear mass, if possible, daily; observe the fasts of the church, as well as certain special austerities; avoid contention, litigation, and unnecessary oaths; cultivate charity towards all, with special obligations towards needy, sick, or afflicted brethren, and practise with more than common fervour the great Christian virtues. The T. are placed under the authority of superiors elected at intervals, and for a stated period, and are liable to an annual visitation, conducted by a priest appointed for the purpose. It is to be observed, however, that none of these obligations were supposed to bind the members under pain of mortal sin.

Such was the celebrated institute of the T., or the Third Order of St Francis. Similar lay associations were organised in connection with the Dominican, Carmelite, and Augustinian, as well as with certain of the more modern orders; and a brotherhood of the same character had already been formed by the Templars. It ought to be added, that the T. institute, properly so called, is quite distinct from that of the lay 'confraternities' which exist in connection with the several orders, and the objects of which are very similar.

TERTIARY, the term applied in the science of Geology (q. v.) to all the strata of the earth's crust above the Cretaceous Rocks, with the exception of those superficial beds which have recently been raised to a distinct group, under the title of the Quaternary System, or Recent Period. There is considerable difference of opinion as to the division-line between the two systems, some including the boulder-clay and its associated beds in the one, and some in the other group. Tertiary is synonymous with Cainozoic, and is divided into the Pleiocene (q. v.), Meiocene (q. v.), and Eocene (q. v.) periods.

TERTU'LLIAN, a Father of the church, and one of the earliest who used the Latin language in written compositions. In one passage, the genuineness of which there is no reason to doubt, he calls himself Septimius Tertullianus. The best manuscripts call him Quintus Septimius Florens Tertullianus. He was the son of a proconsular centurion—that is, a centurion who attended on the proconsul. He was born in Carthage. He was brought up a heathen, and from his own writings we learn that he was licentious in his conduct, and fond of the public shows. We know nothing more of his heathen life. Eusebius describes him as a man exceedingly well acquainted with the laws of the Romans, and his writings bear out the assertion. From this circumstance, some have identified him with a Tertullianus whose name occurs in the index of the Pandects, and have supposed that he acted as an advocate; but the supposition is a mere conjecture. We know nothing of his conversion. He became a presbyter in the church, but whether he held this office in Rome or in Carthage, is matter of dispute, and there are no data to determine the question. It is certain that he visited Rome, and was well acquainted with the affairs of the Roman Church. He also married; and as his wife was a Christian, it is supposed that his marriage took place after his conversion. After remaining a presbyter until he had reached middle age, he became a Montanist. Jerome attributes his adoption of Montanism to the insulting treatment which he received at the hands of the Roman clergy. But this is not likely an entirely accurate account of the matter. Jerome himself had been ill treated by the Roman clergy, and was therefore inclined to blame them; and in the character and general tendency of T.'s opinions, we have ample explanation of his passing over to Montanism. See MONTANUS. He lived to a good old age, remaining a Montanist to the last. We have no clue to precise dates in the history of Tertullian. Jerome states that he flourished under Severus and Antoninus Caracalla. Allix places his birth at 145 or 150 A.D., and his death at about 220 A.D.; but these are conjectures.

T. was a man of strong and violent passions: he loved and hated with intensity. He possessed considerable culture, and was well versed in Roman law, in ancient philosophy, history, and poetry. He was not deficient in philosophical power, but he was narrow, bigoted, and uncharitable. He shews no sympathy with Greek speculation or with freedom of human thought; and he shews little sympathy with the joys and pleasures of man, being strongly inclined to asceticism. We need not wonder, therefore, that he came to believe in the Paraclete of Montanus as the revealer of the perfection of Christianity, and that he adopted the

Montanist opinions, that second marriages were adulteries, and that it was unlawful to flee in times of persecution, and wrong to receive the lapsed back into the communion of the church.

His writings are numerous. Attempts have been made to divide them into those which were written before he became a Montanist, and those written after that event; but the attempts have failed; for in treating many subjects he would have no occasion to say a word in regard to the Paraclete, second marriages, or persecution.

His works are interesting, throwing much light on the internal circumstances of the church, on the social questions which perplexed Christians, on the opinions of heretics, and on the development of doctrine. Of his theology, Neander remarks: 'In Tertullian we find the first germ of that spirit which afterwards appeared with more refinement and purity in Augustine, as from Augustine the scholastic theology proceeded, and in him also the Reformation found its point of connection.' Among the peculiar opinions which he held, may be mentioned his belief in the corporeality of the human soul.

His writings had great influence on the subsequent ages, but especially on Cyprian. Jerome says: 'I saw at Concordia, in Italy, an old man named Paulus. He said that, when young, he had met at Rome with an aged amanuensis of the blessed Cyprian, who told him that Cyprian never passed a day without reading some portion of Tertullian's works; and used frequently to say: *Give me my master*, meaning Tertullian.'

There are many editions of Tertullian; the best is by Franciscus Oehler (3 vols. 8vo, Lps. 1853). The third volume contains the principal dissertations on the life and writings of Tertullian. The works of T., with many dissertations and notes, form the first and second volumes of Migne's *Patrologia Latina*. The English reader will find a full and satisfactory account of T.'s life, writings, and opinions in Bishop Kaye's *Ecclesiastical History of the Second and Third Centuries, Illustrated from the Writings of Tertullian* (8vo, 2d ed., Cambridge, 1829); and in Neander's *Anti-gnosticus, or the Spirit of Tertullian*, translated by J. E. Ryland, and appended to his translation of Neander's *History of the Planting and Training of the Christian Church* (2 vols. 8vo, Lond. 1851).

TE'SCHEN, a town of Austrian Silesia, on the right bank of the Olsa, 38 miles east-south-east of Troppau. Pop. 8000. Here, in 1779, a treaty of peace was concluded between Maria-Theresa and Frederick II., by which the dispute of the Bavarian Succession was brought to an end.

TE'SSERÆ, the small square tiles or cut stones used in forming tesselated pavements.

TEST ACTS, otherwise called *Corporation Acts*, the popular name given to two English statutes imposing certain oaths on the holders of public offices. Act 13 Car. II. c. 2, directs that all magistrates shall take the oaths of allegiance and supremacy, as well as an oath renouncing the doctrine that it is lawful to take arms against the king, and provides that they must receive the communion according to the rites of the Church of England within a year before their election. Act 25 Car. II. c. 1, imposed the like conditions on the holders of all public offices, civil and military, and obliged them in addition to abjure all belief in the doctrine of transubstantiation. These acts, which were practically evaded to a large extent by means of an act of indemnity passed every year, were repealed 9 Geo. IV. c. 17, in so far as regarded the administration of the sacrament, for which a declaration set forth in that act was substituted. A statute of William IV. substituted a declaration for an oath in most government offices. A new form of oath has been substituted for the oaths of supremacy, allegiance, and abjuration by 21 and 22 Vict. c. 48.

TE'STAMENT. See BIBLE.

TESTAMENT. See WILL.

TESTA'TUM is one of the clauses of an English deed, otherwise called the Witnessing or Operative part, commencing at the words, 'Now this indenture witnesseth that,' &c.; and it includes a statement of the consideration-money and the receipt thereof.

TESTER, or **TESTOON**, a flat canopy over a tomb, pulpit, &c.

TE'STICLES. See REPRODUCTION.

TESTIMO'NIUM, in an English deed, otherwise called the Attestation Clause, is that part which states that the party signed the deed, beginning with the words, 'In witness whereof.'

TESTING, in Chemistry, embraces a series of processes, the details of which would occupy far more space than the general plan of this work would admit of. Indeed, testing may be regarded as equivalent to qualitative analysis. As a simple illustration of the process of testing, we will assume that the most common of all chemical compounds, a salt, is submitted for examination. The student must pursue some such course as the following: 1. He must examine the dry substance before the blow-pipe, and note whether (*a*) it is volatile, as are the salts of ammonia and mercury; or (*b*) fusible, as are the salts of potash and soda; or (*c*) infusible, as are the salts of zinc, alumina, magnesia, lime, strontia, and baryta; or (*d*) reducible, as are the salts of silver, tin, lead, bismuth, antimony, and cadmium; and (*e*) whether it gives a coloration to the borax bead, and what that colour is. 2. Having made his blow-pipe examination, he must bring his substance to a finely-divided state, and dissolve it, if possible, in water, and if it is insoluble in that fluid, even with the aid of heat, in hydrochloric or nitric acid. The solution, whether in water or acid, to which no test or reagent has been applied, is termed by Odling (*A Course of Practical Chemistry*, 2d ed., 1865) and others *the original solution;* and to this are added various tests, such as sulphuretted hydrogen, hydrosulphate of ammonia, ammonia, nitrate of silver, &c. The most common effect resulting from the addition of a gaseous or liquid reagent is to cause a *precipitate* or solid deposit of either the base or acid sought for. These precipitates differ in their colour, consistency, &c.; and the student must note not only the colour of the precipitate (although this is the most important point), but also whether the deposit is crystalline, gelatinous, clotty, &c. 3. He must then ascertain to which group the base he is seeking for belongs. There are three great groups of bases; the members of the first group being precipitated from their acid or acidified solutions by sulphuretted hydrogen (hydrosulphuric acid); those of the second group not being thrown down by this reagent, but being precipitated from neutral solutions by hydrosulphate of ammonia (sulphide of ammonium); while those of the third group are not thrown down by either of these reagents. The first group includes tin, arsenic, antimony, bismuth, mercury, lead, silver, copper, and cadmium; the second, nickel, cobalt, manganese, iron, chromium, aluminium, and zinc; and the third, barium, strontium, calcium, magnesium, potassium, sodium, and ammonia. (See Odling, *op. cit.*, p. 64.) 4. Having ascertained to which base the group belongs, the next point is to identify it. For information on this point, the

reader is referred to any of the standard works on qualitative analysis, or on practical chemistry. 5. The base being thus determined, it remains to determine the acid, and in searching for it, the student will be much assisted by a knowledge of the solubility of the most important classes of salts. Knowing, for example, the insolubility of the sulphates of baryta and strontia, he need not search for sulphuric acid in a soluble salt of one of these earths. On the other hand, a salt insoluble in water is not likely to be a nitrate or chlorate, or acetate, or chloride (the only chlorides insoluble in water being chloride of silver and calomel). We cannot enter into the testing for acids further than to observe that the nitrates and chlorates deflagrate; the tartrates and citrates char; the carbonates effervesce when acted on by an acid more energetic than carbonic acid; the silicates, borates, and benzoates are precipitated by hydrochloric acid; and the arseniates and chromates react with hydrosulphuric acid. The presence of any particular acid is more or less indicated by its behaviour, while still in union with the base, with strong sulphuric acid, which in many cases causes the evolution of characteristic fumes or vapours; and amongst the tests especially applicable for the detection of the acids (in acid solutions) are solutions of nitrate of baryta, nitrate of silver, chloride of calcium, and perchloride of iron. As the above remarks apply merely to the detection of the base and acid contained in a single salt, it will readily be understood how much the difficulties are increased when there is a mixture of several salts, or where, in place of a metallic oxide, a vegetable base is present, or where we have to deal with a complicated mixture of organic and inorganic substances, as, for example, in the investigation of the contents of the stomach in a case of suspected poisoning.—The following works on the subject may be referred to: Fresenius's *Qualitative Analysis*, Noad's *Qualitative Analysis*, Greville Williams's *Outlines of Chemical Manipulation*, Bowman's *Practical Chemistry*, and Odling's *Practical Chemistry*.

TESTING CLAUSE, in a Scotch deed, is the last clause, which narrates when and where the parties signed the deed, before what witnesses, the number of pages of which the deed consists, and who was the person who penned the deed. Moreover, if there have been any interlineations or erasures of important words during the engrossing, these should be mentioned in this clause. The clause is an essential part of a Scotch deed, and no deed which is written by another than the party is valid unless the testing clause is regular. The usual form is this: 'In witness whereof, these presents, written on this and the five preceding pages by John Smith, residing at, &c., were subscribed by the parties as follows—viz., by the said A. B. at Glasgow on the 10th day of October 1865, before these witnesses, W. X. of, &c., and Y. Z. of, &c.'—In English or Irish deeds, there is no necessity to enumerate these particulars in the attestation clause.

TEST-PAPERS are made by dipping unsized paper into an alcoholic solution of a vegetable colouring matter which changes colour when exposed to the action of an acid or alkaline solution. The paper, after being gently dried, is cut into slips of a suitable size. Hence, by dipping the appropriate test-papers into any solution, we can ascertain whether it is acid, alkaline, or neutral. Litmus and turmeric are most commonly used as the colouring matters; litmus for the detection of acids, and turmeric for that of alkalies.

TESTU'DO. See TORTOISE.

TESTUDO, in Ancient Warfare, was a defensive arrangement of the shields, by means of which a body of men advancing against a wall for assault or mining sought to protect themselves from the darts and weapons of the defenders. The men standing in close order joined their shields above their heads, the edges overlapping, until the whole resembled the shell of a tortoise (*testudo*).—The name was also applied to a machine moving on wheels, and roofed over, under which soldiers worked in undermining or otherwise destroying the walls in a siege. See BATTERING-RAM.

TE'TANUS (derived from the Gr. *teinein*, to stretch) is one of the most formidable diseases of the nervous system, and is characterised by an involuntary, persistent, intense, and painful contraction or cramp (see SPASM) of more or less extensive groups of the voluntary muscles, nearly the whole of the body being sometimes affected. There is usually a certain degree of order in which the different sets of muscles are affected. The muscles of the neck, jaws, and throat are almost always the first to give evidence of the presence of the disease. 'The patient,' says Dr Watson, who has written a most graphic description of this terrible malady, 'feels a difficulty and uneasiness in bending or turning his head, and supposes that he has got what is called a stiff neck. He finds also that he is unable to open his mouth with the customary facility. At length the jaws close; sometimes gradually, but with great firmness; sometimes (it is said) suddenly and with a snap. In four cases, perhaps, out of five, the disease begins in this way with *trismus* or *lock-jaw;* so that this last is the vulgar name for the complaint. Along with this symptom, or very soon after it, the muscles concerned in swallowing become affected; and in a short time there comes on, what is often the most distressing part of the disorder, an acute pain at the lower part of the sternum, piercing through to the back. This pain depends, it can scarcely be doubted, upon cramp of the diaphragm, and is subject to aggravation in paroxysms. The spasm extends to the muscles of the *trunk;* to the *large* muscles of the extremities; the muscles of the *face;* and last of all, in general to the muscles of the tongue, and of the hands and fingers, which often remain movable at the will of the patient, after all the other voluntary muscles of the body have become fixed.'—*Lectures on the Principles and Practice of Physic*, 4th ed., vol i. p. 568. The muscles that are affected remain permanently contracted till either recovery or death ensues, and some of them, as, for example, the muscles of the abdomen, are so rigid, as when struck by the fingers, to resemble a board, although a perfect remission of the spasm scarcely ever occurs, except sometimes during sleep. Exacerbations of the spasms, on the other hand, commonly occur every ten minutes or quarter of an hour, usually beginning by an increase of the pain at the sternum, and lasting for two or three minutes: and as the disease advances, these paroxysms become more frequent. The powerful muscles of the back generally overcome the muscles in the front of the body, and when this excess of morbid power in the back is marked, the result is that the patient during the paroxysms rests solely on his head and heels, while his body is raised in an arched form. Occasionally the muscular contraction predominates in the opposite direction, and brings the head and knees in contact; and still more rarely, the body is bent to one side.

During the exacerbations, the face of the patient often presents a positively frightful appearance. The tongue is apt to get bitten during the contractions, which are occasionally so violent as to break the teeth, rupture powerful muscles, and at least in one

case, to fracture the thigh-bone. Death usually results from a mixture of causes, but mainly from apnœa (breathlessness), due to the fixed condition of the respiratory muscles, associated with asthenia (loss of power), and flagging of the heart's action.

There are two principal causes of this disease, viz. (1) exposure to cold and damp, and (2) bodily injuries. When tetanus arises from the *first* of these causes, it is termed *idiopathic;* and when from the second, *traumatic.* Idiopathic tetanus is so rare, at all events in this country, that we may pass on at once to the consideration of the traumatic variety. The disease is liable to follow any kind of injury, from a trifling cut or scratch to a compound fracture or the most severe operation, and is much more common in tropical than in temperate climates. The following table, given by Mr Poland in his article 'Tetanus' in Holmes's *System of Surgery,* vol. i. p. 306, gives the relative proportions which the occurrence of tetanus bears to various classes of surgical lesions observed at Guy's Hospital during seven years:

There were of—		
Major and minor operations,	1364 cases—tetanus occurred in	1
Wounds of all varieties, .	594 " " "	9
Injuries and contusions, .	856 " " "	1
Burns and scalds, . .	458 " " "	3
Compound fractures, . .	396 " " "	9
Total, . .	3668	23

From the large experience thus afforded, it appears that tetanus is most frequently met with in the more severe varieties of injury and accident, such as compound fractures, burns, and injuries to the fingers and toes. It is still a disputed point, whether the seat of the injury forms any special connection with the disease. Hennen, one of our greatest authorities on military surgery, observed it oftener after wounds of the elbow and knee; others, again, more frequently from injuries of the thumb and great toe. There is certainly a popular belief that wounds of the ball of the thumb are especially likely to be followed by tetanus.

The interval between the reception of the injury and the first tetanic symptoms commonly varies from the 4th to the 14th day, and rarely exceeds 22 days, some time in the second week being the most common period. As a general rule, the more rapidly the disease comes on, the more fatal will be the result.

Mere *trismus* or lock-jaw may be induced by affections of the teeth, especially by difficult dentition of the wisdom-teeth; but this is a purely local affection, in which the muscular contraction, though persistent, is never increased by painful spasmodic paroxysms, and which usually disappears on the removal of the exciting cause; and the general knowledge of this fact may tend to remove unnecessary terrors. Hysteria sometimes mimics the phenomena of tetanus with marvellous fidelity; and hydrophobia and tetanus have been mistaken for one another, in consequence of the spasm of tetanus sometimes affecting the muscles of deglutition, and inducing a fear of swallowing. There is, however, seldom any serious difficulty in detecting the difference between tetanus and any other disease. But there is a form of poisoning which produces almost every symptom of tetanus, and which may be termed *artificial tetanus.* If strychnia or brucia, or their salts, or vegetable matter containing either or both of these alkaloids, as nux vomica, St Ignatius's beans, or the juice of the upas tiente, be administered, either by the stomach or by inoculation, into the system, it induces all the symptoms of intense tetanus, and there is no test by which to distinguish the results of the disease and of the poisoning, except that, according to Dr Christison, the disease never proves so quickly fatal as the rapid cases of poisoning with strychnia. See NUX VOMICA. And those who wish to study more minutely the comparative symptoms of strychnia-poisoning and tetanus, may consult the authorised *Report of Palmer's Trial.*

In the way of treatment, almost every known medicine has been prescribed, and whatever plan be adopted, a vast majority of the cases terminate fatally. As is the case with certain fevers, so tetanus seems to have a definite course to run; and as Mr Poland wisely suggests: 'All we can do is to enable our patient to weather out the storm by giving him as much strength as possible, and not adding fuel to the fire by all sorts of applications and internal remedies, which have over and over again signally failed. If we can help our patient on one day after another, we gain much: constant watching and constant attention are required by night as well as by day; an unflinching perseverance on the part of the sufferer in carrying out these views; besides the avoidance of all causes of excitement, and more especially the cold air or winds; taking care to preserve a uniform temperature as much as possible.' When, in consequence of the strong contraction of the muscles of the jaw, it is impossible to open the patient's mouth, food and physic should be introduced into the stomach by means of a flexible tube passed through one of the nostrils.

The peculiar form of tetanus that occurs in newly-born children, differs in so many respects from the disease described in this article, that we shall briefly notice it in a separate article under the title of TRISMUS NASCENTIUM.

TETANUS, or LOCK-JAW, occurs in most of the domesticated animals, but most frequently in horses and sheep. It is usually produced by cold and wet, by intestinal worms, obstinate constipation, or injuries. The symptoms usually come on gradually, involve tolerably equally most of the muscular structures, which become hard and rigid; the nose is protruded, the limbs move stiffly, the tail is upraised, the bowels are constipated. The patient must be kept perfectly quiet, and in an airy but tolerably warm place, and plentifully supplied with cold water, and with soft, sloppy, but tolerably nutritive food, which he will usually greedily suck in through his firmly-closed teeth. A full dose of purgative medicine must at once be given; extract of belladonna repeated twice or thrice daily, is occasionally serviceable; any discoverable wound or injury should be fomented or poulticed; bleeding, sedatives, and all causes of irritation must be avoided. In adult animals, most cases are fatal; but amongst young animals, especially when the attack results from exposure to cold, many recoveries occur.

TÊTE-DU-PONT. See BRIDGE-HEAD.

TETRAGONIA'CEÆ, a natural order of exogenous plants, formerly included in *Mesembryaceæ* (q. v.), from which it differs chiefly in the want of petals. The species are herbaceous plants or small shrubs, with alternate, thick, succulent leaves. A few are found on the shores of the Mediterranean, and some in Asia and the South Sea Islands, but the order abounds chiefly in the south of Africa. New Zealand Spinach (q. v.) belongs to this order. Other species are also used like spinach, as *Sesuvium portulacastrum* and *S. repens* in the West Indies. Species of *Aizoon* are among the plants burned for barilla in Spain and the Canary Isles.

TETRAHE'DRON (Gr. *tettares,* four, *hedra,* a side), one of the five regular geometric solids, is a solid bounded by four equilateral triangles. The

best idea of it is gained by considering it as a triangular pyramid, whose three sides and base are equilateral (and therefore equal) triangles. It is a form assumed by some crystals, and in crystallography is considered as a secondary form of the Octahedron (q. v.), produced by removing the alternate angles or edges of the latter.

TE'TRAO AND TETRAO'NIDÆ. See GROUSE.

TE'TRARCH (Gr. *tetrarches*, Lat. *tetrarcha*, 'governor of the fourth part,' i. e., of a country), a title originally designating what is signified by its etymology, the governor of one of four divisions of a kingdom or country; but in the usage of the later Roman Empire, given undistinguishingly to all minor rulers, especially in the east, possessing sovereign rights within their territory, but dependent on the emperor, and in many cases removable at his pleasure. This was especially the case in Syria, where the princes of the family of Herod are called indiscriminately by this title (Luke iii. 1) and by that of king (Matt. xiv. 9). The tetrarch in this latter sense was in truth a sovereign, although a dependent sovereign; and there are even some instances in which it seems to have been applied to really independent sovereigns, when the principality was small and of little importance.

TE'TRA-STYLE, a portico of four columns.

TETUA'N, a seaport town and small province on the north coast of Africa, 22 miles south of Ceuta, and 40 miles south of Gibraltar. Area, 914 sq. m.; pop. 17,600. It is surrounded by walls, flanked with towers, and is defended by a castle. Its harbour does not admit large vessels; but a brisk trade is carried on in wool, silk, girdles, leather, cotton, &c., and it exports provisions largely to Ceuta. Oranges are grown in great abundance in the vicinity, and are exported to Spain, Gibraltar, Oran, and recently to England. T. was taken by the Spaniards under O'Donnell (q. v.), February 1860; and the treaty of Madrid, by which the city was evacuated in favour of the Spaniards, was concluded October 30, 1861.

TETZEL, or TEZEL (properly *Diez* or *Diezel*), JOHN, well known in connection with the controversy regarding indulgences, out of which the first beginnings of the Reformation took their rise, was born at Leipzig between 1450 and 1460. His father was a goldsmith of that city. T., after completing the ordinary studies of the period in the university, entered the Dominican convent of St Paul in 1489, and soon established a reputation as a popular and effective preacher. His personal character is a subject of much controversy. The questions as to the teaching of T. are more important. His ability and success as a preacher led to his being intrusted with the charge of preaching an indulgence, first on behalf of the Teutonic Knights, and afterwards, in 1516, on the far more momentous occasion of the celebrated indulgence published in favour of contributors to the fund for building the church of St Peter's at Rome. In the discharge of this commission, it cannot be doubted that T. went to extremes which it is impossible to justify; but the worst charges, and especially that of preaching the efficacy of indulgences without repentance, and of offering anticipatory pardons for future sin, are strongly denied by Roman Catholic writers as being contradicted not only by contemporary authorities, but also by the very instructions contained in his official commission. Much of the obloquy which he drew upon his cause was produced by the pomp and apparent luxury in which he travelled about upon his mission. It was in opposition to the preaching of T. that Martin Luther published his celebrated theses, on the 31st October 1517. T. replied first by publicly burning these obnoxious propositions; but he afterwards published a series of counter-theses (which were burned in retaliation by the students of the university of Wittenberg); and in May 1518, a detailed reply to Luther's celebrated Sermon on Indulgences. On the arrival of the papal delegate Miltitz, T. addressed to him a letter in reply to the charges of his adversaries; but notwithstanding this defence of his conduct, he was summoned to appear before Miltitz in Leipzig in the January of the following year, and underwent a severe rebuke for the excesses in language, and the improprieties in proceeding, which had brought so much scandal upon the church. Miltitz threatened him, moreover, with the severest animadversions on the part of the pope. He was required in consequence to withdraw to his convent at Leipzig, where he died in the August of the same year, 1519, according to some of the plague, but according to another account, of the chagrin and mortification resulting from the judgment of the papal representative.—See on the one side, Hechlein, *Vita Tezelie;* Hofmann, *Lebensbeschreibung des Ablass-predigers Dr Joh. Tetzel* (Leip. 1844); and on the other, Schrödl, in Wetzer's *Kirchen-Lexicon*, art. 'Tetzel,' x. 767.

TEUTOBURGER WALD (Lat. *Teutobergiensis Saltus*). See HERMANN.

TEUTO'NIC, a term applied to a group of nations, as well as of languages, forming an important division or stem of the Aryan (q. v.) family. The T. languages will be found enumerated and classified in the table at the end of the article PHILOLOGY. The T. stock of nations, as they exist at the present day, is divided into two principal branches: (1) The Scandinavian, embracing Danes, Swedes, Norwegians, Icelanders; and (2) the Germanic, which includes, besides the German-speaking inhabitants of Germany proper (see GERMANY) and Switzerland (q. v.), also the population of the Netherlands (the Dutch), the Flemings of Belgium, and the descendants of the Anglo-Saxons in Great Britain, together with their offspring in North America, Australia, and other British colonies. It is necessary in this case, as in all similar cases, to guard against making language the sole test of race. In many parts of Germany where German now prevails, Slavic dialects were spoken down to recent times, and in some places are not yet quite extinct. And in Great Britain, it is unreasonable to suppose that the Anglo-Saxon invaders exterminated the native Celtic population, or even drove more than a tithe of them into the Highlands. The mass undoubtedly remained as subject serfs, learned the language and customs of their masters, and gradually amalgamated with them; so that, in point of blood, the English are perhaps as much Celtic as Teutonic.

Of the various tribes and nations spoken of as inhabiting Northern Europe in ancient times, it is often difficult to determine which were really of Germanic race, and which Celtic or Slavic; the classic writers having no skill in detecting the affinities of language, had only confused notions of ethnology. Of undoubted German nations who took part in the destruction of the Roman Empire, the most prominent were the Goths (q. v.), Lombards (q. v.), Vandals (q. v.), and Franks (q. v.). The term Teutonic is derived from *Teutones*, the name of a nation or tribe first mentioned by Pytheas, who wrote about 320 B.C., as then inhabiting a part of the Cimbric Chersonesus, or Jutland. For the next 200 years there is no further mention of the Teutones, that is, not until 113 B.C., when they appear in history as ravaging Gaul, and in conjunction with

the Cimbri and Ambrones, threatening the very existence of the Roman republic. The Cimbri having gone into Spain, the Teutones and Ambrones were at length defeated by C. Marius in a great battle at Aquæ Sextiæ, or Aix, in Gaul, 102 B.C., in which from 100,000 to 200,000 of the invading army were slain, and many thousands made prisoners. A similar victory was gained by Marius in the following year over the Cimbri in the plains of Lombardy. It is disputed among ethnologists and historians whether the Cimbri so defeated were of the Celtic or of the Germanic race, and doubts have even been thrown on the claim of the Teutones to be considered Germans, although the best German scholars hold the claim to be established. Be that as it may, Roman writers, after the time of Cæsar and Tacitus, began to use the adjective Teutonicus as equivalent to Germanicus; and this practice was adopted in the middle ages by Germans writing in Latin. The native term was *theodisk*, from Goth. *thiud*, people; and it is from this word and not from Teutonic, that the modern *Deutsch* is derived. See GERMANY.

TEUTONIC KNIGHTS, one of the more celebrated of the military and religious orders to which the Crusades gave birth. The sufferings of the Christian soldiers at the siege of Acre excited the sympathy of certain merchants of Bremen and Lübeck, who rendered such important services by the erection of hospitals and otherwise, that Duke Frederick of Swabia, with the sanction of Pope Clement III. and the Emperor Henry VI., enrolled them in an order of knighthood, as the Teutonic Knights of St Mary of Jerusalem. Only Germans of noble birth were made admissible to the order, the original founders having probably been ennobled before being enrolled. The members were at first all laymen, but priests were soon admitted as chaplains; and there was also added about 1221, a class of half-brothers similar to the serving-brothers of the Templars and Hospitallers. The habit of the order was a white mantle with a black cross; and the knights took vows of poverty and chastity, which in later times were not very strictly interpreted. Their first seat was Acre. On the overthrow of the kingdom of Jerusalem, the grand master removed to Venice, and from thence in 1309 to Marienburg, on the banks of the Vistula. In 1237, this order became united with the Brethren of the Sword in Livonia. In the course of the 13th c., the Teutonic Knights were, with the sanction of the pope, engaged in a bloody war to enforce Christianity on the heathen nations inhabiting the southern shores of the Baltic, which resulted in the acquisition by the order of Prussia, Livonia, Courland, and other adjoining territories. Warriors from all parts of Europe in that and the following century joined their standard, including Henry IV. of England, accompanied by 300 attendant knights and men-at-arms. The conquests of the order raised it to the rank of a sovereign power, with a territory extending from the Oder to the Baltic, and embracing a population of between two and three millions, the grand master having his seat at Marienburg in Prussia. The decline of the order began in the 15th c., and its fall was brought about partly by internal dissensions, and partly by the attacks of neighbouring states. Sigismund of Poland wrested West Prussia from the knights; and Albert of Brandenburg, who was chosen grand master in hopes of his aiding the order against Poland, ended an unsuccessful war with Sigismund by an arrangement, according to which the territories of the order in East Prussia were formed into a duchy, to be held by Albert and his successors. Mergentheim in Swabia then became the seat of the grand master, who was recognised as a spiritual prince of the empire. At the peace of Presburg in 1805, the Emperor of Austria obtained the rights and revenues of the grand master; but in 1809 the order was abolished by Napoleon, its lands passing to the sovereigns in whose dominions they lay. The Teutonic order, however, still continues to preserve a titular existence in Austria.

TEW'KESBURY, an ancient market-town and parliamentary and municipal borough of Gloucestershire, in the vale of Evesham, on the Avon, and near its confluence with the Severn, 10 miles north east of Gloucester. The parish church, an ancient and noble edifice in Norman, is the most noteworthy architectural feature. Hosiery, shoes, nails, leather, and malt are manufactured, and there is an extensive carrying-trade, of which T. is the centre, on the Avon and Severn; pop. about 5000. T., a very ancient town, appears to be of Saxon origin. Within half a mile of it was fought (May 14, 1471) the famous battle of T., in which the Yorkists under Edward IV. (q. v.) and Richard III. (q. v.) inflicted a signal defeat on the Lancastrians.

TE'XAS, one of the south-western of the U. S. of America, is bounded on the S.-W. by Mexico, from which it is separated by the Rio Grande; and on the E. by Arkansas and Louisiana. Area, 237,504 sq. m. Pop. (1860) 601,039, of whom the entire coloured population — 186,682 — were slaves; (1880) 1,591,749. It is divided into 161 counties. Among the chief towns are Austin, the capital; Galveston, the principal seaport; the German town of New Braunfels, Houston, Marshall, Indianola, Corpus Christi, &c. Nearly the whole gulf-coast is lined with bays, generally long and narrow, with shallow inlets—that of Galveston being 12 feet. The chief rivers are the Red River, which separates Texas from the Indian territory; the Sabine, Trinity, Colorado, and Rio Grande. These rivers, mostly navigable from 300 to 400 miles, run south-east, nearly parallel to each other, and empty into the Gulf of Mexico. The country on the coast of the gulf is level, with a gradual ascent, the middle region undulating with rolling prairies; the west is a high table-land, and the salt plains and staked plains (*el llano estacado*) on the border of N. Mexico, are deserts 3000 to 4000 feet above the sea, without trees, and in the summer without grass. There are a few small mountains in the west—spurs of the Rocky Mountains. The river-bottoms are well timbered. In Eastern T., wooded lands, called cross-timbers, alternate with prairies, and the country has a park-like and delightful aspect. The coast-region is formed of alluvial beds of sand or gravel; the middle, of outcrops of tertiary formations. In some places, petroleum is found on the surface of acid springs, and the earth is so charged with bitumen as to be used for fuel. There are fertilising marls and gypsums, brown coal or lignite in beds of six inches to eight feet, and beds of hematite. Beyond the tertiary lies a wide range of cretaceous formations, beds of limestone, sandstone, clays, marls, and beyond these, 5000 sq. m. of coal-measures, four distinct seams, of eight or nine feet in all, resting on fire-clay. There are also fine marbles, and some deposits of lead and copper. The soil is of great fertility, the coast producing the finest cotton, sugar, &c.; and the interior, wheat, Indian corn, tobacco, fruits of all kinds, with abundant pasturage—making it one of the finest cattle-countries in the world. The climate is pure, temperate, and remarkably salubrious. The thermometer ranges from an average of 81° F., the hottest week in summer, to 29°, the coldest week in winter. The eastern region is rainy; the middle, moderate; the south-western, dry. The vegetation

is in the greatest variety, from the oak, cedar, and pine, to the palmetto, mezquit, and nopal, which feeds the cochineal insect, with figs, oranges, grapes, vanilla, and flowers in wonderful profusion. The prairies abound in buffalo, immense herds of wild horses, and the forest with deer. There are also the puma, jaguar, black bear, wolf, &c. The coasts, bays, and rivers abound in the finest fish, shell-fish, turtles, &c. Though the country is generally level, it is not destitute of wild and grand scenery. In some places are found gigantic animal fossils and silicified trees. In 1870, there were 2,964,836 acres under cultivation, producing 20,554,538 bushels of corn, 415,112 bushels of wheat, 762,663 of oats, &c. The total value of the live stock was $37,425,194. The chief manufactures are salt, iron, and woollen goods. There is a large trade with Mexico and with New Orleans. The chief exports are cotton, sugar, tobacco, cattle, and wool. The state Deaf and Dumb, Orphan, Blind, and Lunatic Asylums have each an endowment of 100,000 acres of state lands. There is a state school-fund of $2,575,000, and the income of the educational institutions of all classes for 1870 was $414,880. The assessed value of property for the same year was $149,732,929. In 1873 there were 1232 miles of railroad completed and in operation in the state of Texas.

La Salle, the French explorer, erected a fort on Matagorda Bay, 1687. A Spanish settlement and mission was formed in 1690, but soon abandoned. In 1715, the country was settled by the Spaniards, under the name of New Philippines, and several missions established; but the Comanche and Apache Indians, among the most warlike in America, and still the terror of the border settlements, hindered the progress of the country. In 1803, when Louisiana was ceded by France to the U. S., T., claimed by both Spain and the U. S., became a disputed territory. From 1806 to 1816, settlements were formed, and several attempts made to wrest the country from Spain. In one of these, in 1813, 2500 Americans and Mexicans were killed, and 700 inhabitants of San Antonio. Mina, a Spanish refugee, gained some successes, but was defeated and shot. Lafitte, a Gulf pirate, made a settlement at Galveston in 1815, but it was broken up in 1821. In 1819, the river Sabine was established as the boundary. In 1820, Moses Austin, an American, got a large grant of lands in T. from the Mexican government, and began a settlement, which rapidly increased; but many of the settlers were of so lawless a character, that in 1830, the government forbade any more Americans coming into Texas. In 1833, a convention of settlers, now 20,000 in number, made an unsuccessful attempt to form an independent Mexican state; and in 1835 a provisional government was formed, Sam Houston (q. v.) chosen commander-in-chief, and the Mexicans driven out of Texas. Santa Anna, President of Mexico, invaded the country with an army of 7500, but, after some successes, was entirely routed at San Jacinto, April 21; and T. became an independent republic, acknowledged in 1837 by the United States, and in 1840 by England, France, and Belgium. In December 1845, T. was annexed to the United States, but was invaded by Mexico, which had never acknowledged its independence. A war followed, in which Mexico was defeated. In February 1861, T. joined the Secession, and furnished many soldiers and immense supplies to the Confederate armies. In February 1866, the ordinance of Secession was annulled, and in 1870 the reconstruction was completed, and regular civil government restored.

TEXEL, The, an island in the province of North Holland, separated from the Helder by a narrow strait, called the Marsdiep, contains about 35,000 acres of arable and pasture lands, and has a population of 6408. Many sheep are kept, producing fine wool. Fishing, ship-building, grinding corn, &c., are also sources of prosperity. There is much wealth in the island, but still (1871) no steamboat communication exists with the mainland. The northern part is called Eijerland, or the egg-country, immense flocks of birds coming thither from Scandinavia to deposit their eggs.

TE'XTILE FABRICS. See Weaving.

TEZCU'CO (i. e., 'place of detention'), an ancient and much decayed city of Mexico, stands on the east shore of the lake of the same name in the state, and 16 miles east-north-east of the city of Mexico. In former times, it was the capital of a great state, and was the second city in Mexico. During the early part of the 15th c., the city rose to its greatest splendour. It then contained ranges of stately mansions, in which the nobles resided, and a magnificent and vast pile of buildings, which served as the royal residence and as public offices. T. is now a poor place, filled with heaps of rubbish and ruins, and containing only 5000 inhabitants.

THACKERAY, William Makepeace, novelist and satirist, was born at Calcutta in 1811. He was of a good old English family, represented about the middle of last century by Dr Thackeray, an eminent scholar, and head-master of Harrow. His father was in the civil service of the East India Company, and dying young, he left his son a fortune of £20,000. The latter, when a boy of seven years of age, was sent to England, and placed in the Charterhouse School, that ancient Carthusian foundation, which he loved to commemorate in his writings. He next went to Cambridge, but left the university without taking a degree. In 1831 he was at Weimar, and saw Goethe. His ambition was to become an artist, and he travelled over most of Europe, studying at Paris and Rome. His drawings were not without merit; they were quaint, picturesque, and truthful, but somehow they missed the bright touches of a master-hand. He next took to literature, beginning with rare patience and contentment at the lowest step of the ladder. Under the characteristic name of Michael Angelo Titmarsh, or that of Fitz-Boodle, he became a constant contributor to *Fraser's Magazine*, and wrote for it two of the best of his minor works, *The Great Hoggarty Diamond*, and *Barry Lyndon*. The latter is the story of an Irish sharper, and is told with a spirit, variety of adventure, and humour worthy of Le Sage or Fielding. Under the pseudonym of Titmarsh, he also published *The Paris Sketch-book* (2 vols. 1840), *The Second Funeral of Napoleon, and Chronicle of the Drum* (1841), and the *Irish Sketch-book* (2 vols., 1843). The greater part of T.'s fortune having been spent in foreign travel and unsuccessful speculations at home, he continued to work steadily at literature as a profession. He was never widely popular, but a few good judges appreciated his keen wit, observation, and irony, and his command of a style singularly pure, clear, and unexaggerated. The establishment of *Punch* afforded a more congenial field for T., and his *Snob Papers* and *Jeames's Diary* were hailed with delight by all readers. Their author's reputation was still more advanced by his novel of *Vanity Fair* (1846—1848), published in monthly parts in the style of *Pickwick*, and illustrated by the novelist himself, or, as he expressed it, 'illuminated with the author's own candles.' During the progress of *Vanity Fair* appeared *Notes of a Journey from Cornhill to Grand Cairo*, being an account of a journey undertaken for the benefit of his health; also *Mrs Perkins's Ball*, a short Christmas tale, and two works of a similar kind entitled *Our Street*, and *Doctor Birch and his Young Friends*. In 1849, he began a second serial fiction, *Pendennis*.

in which much of his own history and experiences are recorded. Next followed *Rebecca and Rowena* (1850), and *The Kickleburys on the Rhine* (1851). The latter work was sharply criticised by the *Times*, and T. replied in a caustic and humorous *Essay on Thunder and Small Beer*, prefixed to a second edition of the satirical sketch. In 1851, the indefatigable novelist delivered a course of lectures on the *English Humorists of the Eighteenth Century*—light, graceful, discriminating sketches, with passages of real power and eloquence. In 1852—1855, appeared two more novels, the most richly imaginative and highly finished of his works, *Esmond* and *The Newcomes*. These were followed by *The Virginians* (a much inferior novel), by *Lectures on the Four Georges* (first delivered in America), by *Lovel the Widower* and *Philip* (two short tales of somewhat coarse texture), and by a series of pleasant gossiping essays, entitled *Roundabout Papers*. These originally appeared in the *Cornhill Magazine*, of which T. was for a time editor; and in the same miscellany he had begun and published part of a new novel, *Dennis Duval*, which promised to be one of the most carefully elaborated and successful of his works of fiction. He contemplated also *Memoirs of the Reign of Queen Anne*, which would have served as a continuation to Macaulay's *History*. He knew that period well, from his previous studies for *Esmond*, and as a moral anatomist and master of English he stood unrivalled. But, alas! such dreams and anticipations were suddenly dispelled. To the grief of all lovers of genius and of manly and noble character, T. was cut off in the fulness of his powers in his 52d year, dying alone and unseen in his chamber before daybreak on the morning of the 24th of December 1863. His medical attendants found that death was caused by effusion on the brain, and that his brain was one of the largest, weighing no less than 58½ ounces.

In his delineation of the character and genius of Fielding, T. has drawn his own. He had the same hatred of all meanness, cant, and knavery, the same large sympathy, relish of life, thoughtful humour, keen insight, delicate irony, and wit. There was, however, one personal difference: Fielding was utterly careless as to censure of his works, whereas his successor was tremblingly alive to criticism, and was wounded to the quick by the slightest attack. His morbidly delicate organisation made him exquisitely susceptible of either pain or pleasure. He had suffered much from physical maladies and from domestic calamity; and his earlier works, especially his *Vanity Fair*, were tinged with a degree of cynicism which seemed to countenance the charge of his unfriendly critics, that he delighted in representing the baser side of human nature, and was sceptical as to the existence of real virtue in the world. His strength lay in portraying character rather than inventing incidents; and in Becky Sharp, Colonel Newcome, Harry Foker, Laura Pendennis, and Paul de Koch, to say nothing of the picaroon, Barry Lyndon, he has left us a living gallery, certainly not surpassed by any modern novelist. In his later writings, the dark shades no longer preponderate. The mellowing influence of years and sickness, and calmer as well as more extensive observation of life, had sunk the merciless satirist in the genial humorist and philosophic observer. He had still ample scorn for falsehood and vice, and satire for folly and pretence; but he had also smiles and tears, and tenderness and charity, that gave a moral beauty and interest to the last decade of his brilliant career as an author.

THA'IS, an Athenian courtesan, famous for her wit and beauty, who was in Asia along with Alexander the Great, and according to Cleitarchus—a doubtful authority—induced the Macedonian king, when excited with wine, to set fire to the palace of the Persian kings at Persepolis. After his death, she lived with Ptolemy Lagi, by whom she became the mother of several children.

THALASSIDRO'MA. See PETREL.

THALBERG, SIGISMUND, a very eminent living pianist, who was born at Genéva in 1812, but received the greater part of his musical education at Vienna, where he was a pupil of Hummel. He made his first public appearance in 1827, and his *début* in Paris in 1835. After residing for a number of years in America, he lately returned to Europe. In graceful and brilliant execution, and still more in manual dexterity on that instrument, he has hardly a rival. His compositions are principally fantasias and variations.

THALEI'A, or THALIA (Gr. the blooming one), one of the nine Muses (q. v.), generally regarded as presiding over comedy. By Apollo, T. became the mother of the Corybantes.

THA'LÉS, an early Greek philosopher, founder of the Ionic or physical school of philosophy, and one of the Seven Wise Men (q. v.), was a native of Miletus, in Asia Minor, and flourished towards the close of the 7th c. B.C. Very little is known regarding his life. He is said to have recommended the Ionians, who were menaced by the Persians, to form a federation against their powerful enemy, and to select Teos as the capital. At a later period, we are told he induced the Milesians to withdraw from a union with Crœsus against Cyrus. He is also said to have predicted the eclipse of the sun which happened in the reign of Alyattes. His claim to the title of sage (as in the case of his compeers) was due to his practical wisdom rather than to his speculative achievements. Nevertheless, T. has a name in the history of speculative philosophy. He is even regarded by some as the *first* Greek that speculated on the constitution of the universe. According to him, the original principle of all things is water, from which everything proceeds, and into which it is again resolved. It would appear also that in connection with this doctrine he had some idea of a soul or force in water productive of all the phenomena we see, but it is impossible to ascertain the extent of his belief in an immaterial power. Most probably, his philosophy was a form of Pantheism, rather than of Theism. None of T.'s speculations were committed to writing, and it is only from the notices of later Greeks, such as Herodotus, Aristotle, &c., that we can gather an idea of the character of his thinking.—See Ritter's *Geschichte der Ionischen Philosophie* (Berl. 1821), Lewes's *Biographical History of Philosophy*, and Prof. Ch. A. Brandis, in Smith's *Dic. of Gr. and Rom. Biog.*, art. 'Thales.'

THA'LLIUM (symb. Tl, equiv. 204, spec. grav. 11·9) is a metal which derives its name from the Greek word *thallos*, green, because its existence was first recognised by an intense green line appearing in the spectrum of a flame in which T. is volatilised. It was discovered by Mr Crookes, the editor of the *Chemical News*, in 1861, in the seleniferous deposit of a lead chamber of a sulphuric acid factory in the Harz Mountains, where iron pyrites is employed for the production of the acid. In the following year, it was obtained in larger quantities from a similar source by M. Lamy, who exhibited magnificent specimens of it in solid bars at the last Great Exhibition in London. T. is slightly heavier than lead—a metal which it resembles in its physical properties. It is very soft, being readily cut with a knife, or drawn into wire; and its freshly-cut surface exhibits a brilliant metallic lustre and grayish colour, somewhat between those of silver and lead. In contact with the air, it tarnishes more rapidly than lead, and becomes coated with a thin layer of

oxide, which preserves the rest of the metal. It fuses below a red heat, and is soluble in the ordinary mineral acids. With oxygen, it enters into two combinations —viz., *Protoxide of Thallium*, which is a strong base, forming well-defined salts with acids; and *Thallic Oxide*, which is soluble in water, may be obtained in crystals, and forms soluble salts with the alkalies.

There is a difference of opinion as to whether the salts of T. are or are not powerful irritant poisons. Lamy (with the view of testing the statement of Paulet, that the salts are poisonous) dissolved 75 grains of the sulphate in milk; and he found that this quantity sufficed to destroy two hens, six ducks, two puppies, and a middle-sized bitch. In one experiment, a grain and a half proved fatal to a puppy. Mr Crookes, on the other hand, although much exposed to the fumes of this metal, suffered no particular effects from them; and he swallowed a grain or two of the salts without injury. He found that the latter have a local action on the hair and skin, staining the former, and rendering the latter yellow and horny.—For further details regarding this metal, the reader may consult Mr Crookes's Memoirs in the *Philosophical Transactions* for 1862, and in the *Chemical News*, and Lamy's Memoir in the *Annales de Chimie et de Physique* for 1863.

THALLO'GENOUS PLANTS are those acotyledonous plants which exhibit the greatest simplicity of structure, consisting of a mere Thallus (q. v.) with reproductive organs. Of this description are *Algæ*, *Characeæ*, *Fungi*, and *Lichens*. When apparent leaves exist in any of these, they do not exhibit the symmetry always found in true leaves; and although some of them have stems or stalks, which attain, as in some sea-weeds, both to a considerable age and to great strength, all is composed of cellular tissue without any proper woody fibre.—In the botanical system of Lindley, the T. P. form a class, under the name *Thallogens;* and in that of Endlicher, a corresponding place is assigned to them under the name *Thallophyta.*

THALLUS, in Botany, a structure composed of

Vertical Section of Thallus of *Parmelia parietina*, shewing spores, &c.

Copied from Lindsay's *British Lichens* (London: Routledge).

cellular tissue, without woody fibre, which in some of the lower cryptogamic orders, as *Algæ*, *Fungi*, and *Lichens*, constitutes the whole plant, except the reproductive organs, which are situated in or upon it. The T. assumes very various forms, sometimes crust-like, sometimes spread out like a leaf, simple, lobed, or branched; or, as in mushrooms, it becomes a stalk, cap, and gills.

THAMES (Lat. Tham-*esis*, the 'broad Isis;' *isis* being identical with *esk*, *ex*, *ouse*, &c., all from Cel *uisg*, water), the most important river of Great Britain, and the longest in England, flows east-south-east across the south portion of the country, extending almost from sea to sea. Its remotest springs—those of the upper waters of the Churn—rise on the south-east slope of the Cotswold Hills, 3 miles south of Cheltenham, and 7 miles west of the Severn at Gloucester. The springs unite about a mile from their sources, and form the Churn, which flows south-east 20 miles to Cricklade, and there receives the T., which joins it from the west after a course of 10 miles. The T., or Isis, then flows east-north-east for about 35 miles, when, curving south-east, it passes Oxford, and flows on to Reading, where, after receiving the Kennet from the west, it again changes its course; and with a generally eastward course, it passes Windsor, Eton, Richmond, London, Woolwich, and Gravesend, a few miles below which it expands into a wide estuary, and enters the North Sea. The length of the T. is estimated at 250 miles, the area of its basin at upwards of 6000 sq. miles. Throughout the greater part of its course, it is of importance as forming the boundary-line between several of the southern counties. Passing Cricklade, it forms part of the northern boundary of Wilts, and below this point it separates the counties of Oxford, Buckingham, Middlesex, and Essex on the north from those of Berks, Surrey, and Kent on the south, except certain outlying bits of some of these counties. Its chief affluents are the Coln, Leach, Windrush, Cherwell, Thame, Colne, Lea, and Roding, on the left; and the Kennet, Loddon, Darent, Mole, and Medway, on the right bank. At Vauxhall Bridge, the width of the river is about 230 yards; at London Bridge, 290 yards; at Woolwich, 490 yards; at Gravesend Pier, 800 yards; three miles below Gravesend, 1290 yards; and at its mouth, between Whitstable and Foulness Point, about 8 miles below the Nore, it is 18 miles across. At the Nore Light, the commonly reputed mouth of the T., the breadth is 6 miles. The river is navigable for barges to Lechlade, upwards of 200 miles above its mouth, and it is connected with the Thames and Severn, Oxford, Wilts and Berks, Grand Junction, and several other important canals, by means of which it maintains free communication with the west and south coasts, and with all parts of the interior of the country. Vessels of 800 tons can reach St Katharine's Docks, while those of 1400 tons can ascend to Blackwall, 6 miles below London Bridge. The part of the river immediately below London Bridge is called the *Pool;* and the part between the Bridge and Blackwall is called the *Port.* Two embankments have recently been formed, one on the north shore from Blackfriars Bridge to Westminster, and one on the south shore from Westminster Bridge to Vauxhall. See LONDON.

THANA'TICI is the term used by the Registrar-general, Dr William Farr, in his *Nosology*, to indicate 'lesions from violence tending to sudden death.' These lesions are the direct results of physical or chemical forces, acting either by the will of the sufferer or of other persons, or accidentally.

THANE, or THEGN (A.-S. *thenien*, analogous to Ger. *dienen*, to serve), a title whose use in the early

feudal ages has been the subject of much discussion. In England, in Saxon times, the king's thane was a 'miles emeritus,' who, on the cessation of his actual service about the king's person, received a benefice or grant of land. The term 'miles,' when used by Bede, is uniformly rendered 'cyninges thegn' by his Saxon translator. In the 10th c., all who would, in the feudal era, have been known as tenants *in capite*, were thanes. After the Conquest, thanes and barons are classed together; and in Henry I.'s time, the terms seem to be used synonymously. The office or dignity appears to have been attached to particular estates; thane lands are frequently mentioned in Domesday. After the reign of Henry II., the term fell into disuse. The title thane was introduced at a later period into the northern parts of Scotland, where, however, it did not express the same rank and dignity as in England; the tenure not being military, but in fee-farm.—The Scottish thane seems to have been a hereditary tenant, paying the sum at which the land stood in the king's rental, and retaining his ancient authority strengthened and legalised. The title was in occasional use in Scotland down to the end of the 15th century. Hector Boece's notion of the Scottish thanes being all made earls, which has been adopted in Shakspeare's *Macbeth*, is devoid of historical foundation.

THA'NET, Isle of, forms the north-eastern corner of the county of Kent (q. v.), from the mainland of which it is cut off by the river Stour and its branches, and is bounded on the N. and E. by the sea. It is 10 miles in length, and from 4 to 8 miles broad; and contains 26,500 acres, of which 23,000 are arable, and 3500 in marsh and pastures. The surface is high, but in the main, level; the soil is in general light and chalky; the island, however, is rich and fruitful—agriculture being successfully pursued. Besides the ordinary crops, canary and radish seeds are largely grown. On the shores of the island are the well-known watering-places, Ramsgate, Margate, and Broadstairs; and on the North Foreland, in the north-east, there is a light-house, 340 feet above sea-level, and visible at the distance of 22 miles. The population in 1871 was 42,129; in 1881, 60,646.

The Isle of T., the British name of which was *Ruim* (a headland), was at one time separated from the mainland by a sea-passage, called the Wantsome, which in Bede's time was one-third of a mile wide, and was passable only at Sarre and Wade. The Wantsome was the general sea-passage toward London for the Danish ships, but in 1500 it became finally closed.

THANN, a town of Alsace, in the former French department of Haut-Rhin, prettily situated at the foot of a hill, crowned by the ruins of the castle of Engelburg, 13 miles west-north-west of Mulhouse. It contains a superb Gothic church, surmounted by a spire of delicate open work upwards of 300 feet high. Cotton cloths, chemicals, and machinery are manufactured.

THA'SOS, the most northerly island in the Ægean Sea, lies a few miles off the coast of Macedonia. Area 40 miles; pop. about 6000, who are scattered over a dozen villages. T. is mountainous, and on the whole, barren. The description of it given by Archilochus is still applicable: 'An ass's backbone overspread with wild wood.' It exports some oil, honey, and timber. In ancient times, the island was famous for its gold mines, which appear to have been worked from a very remote antiquity, and which, immediately before the Persian wars, yielded upwards of 300 talents yearly; but they have long since been abandoned. Some remains of the ancient town of T. still exist.

THEA. See Tea.

THE'ATINES, one of the more modern religious brotherhoods of the Roman Catholic Church, which played a very important part in the well-known internal movement for reformation which took place in central and southern Italy towards the middle of the 16th c., and which Ranke has described in his *History of the Popes*. The founders of this association were a party of friends: Cajetan di Thiene; John Peter Caraffa, at that time Bishop of *Theate* (from which the Congregation took the name *Theatine*); Paul Consiglieri; and Bonifazio di Colle. Cajetan and Caraffa, in concert with the two other friends named above, having resigned all their preferments, obtained a brief of Clement, dated June 25, 1524, formally constituting the new brotherhood, with the three usual vows, and with the privilege of electing their superior, who was to hold office for three years. One peculiarity of their vow of poverty deserves special notice: they were forbidden to possess property, and were to subsist entirely upon the alms of the faithful; and yet they were strictly forbidden to beg, or in any way to solicit charitable contributions. Their first convent was opened in Rome, and F. Caraffa was chosen as the first superior. He was succeeded in 1527 by Cajetan, and the Congregation began to extend to the provinces. After a time, however, it was thought advisable to unite it with the somewhat analogous order of the Somaschans; but this union was not of long continuance; Caraffa, who was elected pope, under the name of Paul IV., having restored the original constitution in 1555. By degrees, the T. extended themselves, first over Italy, and afterwards into Spain, Poland, and Germany, especially Bavaria. They did not find an entrance into France till the following century, when a House was founded in Paris under Cardinal Mazarin in 1644. To their activity, devotedness, and zeal, Ranke ascribes much of the success of that remarkable reaction against Protestantism which took place in the latter half of the 16th century. In later times, however, they do not appear to have played any notable part. Their most remarkable member in modern times has been the celebrated Sicilian, Father Ventura, author of the well-known work *Bellezze della Fede*, and familiar to Englishmen by the part which he took in the Italian revolution of 1849. At present, the Theatine order is confined to Italy and Sicily.

THE'ATRE, a place for public representations, chiefly of a dramatic or musical description. Theatres are of very ancient origin. They were found in every Greek city, both at home and in the colonies, and many very interesting specimens of the Greek theatres still exist in very good preservation. These were not built like modern theatres, with tiers of galleries rising one over the other, but were constructed with concentric rows of seats rising in regular succession one behind and above the other like the steps of stairs. These seats were frequently cut in the solid rock; and a place where the natural curve and slope of the ground rendered such excavation easy, was generally chosen. The seats, or audience department, were arranged in a semicircular form. In the centre, at the lowest point, stood the orchestra; and the proscenium, or place for the dramatic representation, formed the chord of the semicircular auditorium. Behind this was the scena, closing in the building with a solid wall, generally ornamented with pillars, cornices, &c. There was no roof, but the audience was probably protected from the sun's rays by a curtain stretching across the theatre. This form of theatre was also that adopted by the Romans, who built or excavated

large theatres in many of their important towns. The theatre of the Romans differed from their *Amphitheatre* (q. v.), the former being semicircular, the latter oval, and with seats all round. Of the theatres still remaining, that of Orange, in the south of France, is one of the finest, the auditorium being 340 feet in diameter. The illustration (fig. 1) shews the general form of these ancient theatres; and in this case the scena is more elaborate than usual. During the middle ages, theatres were unnecessary, and were never built. The few dramatic performances then in use, which were chiefly of the nature of holy mysteries, were represented in the cathedrals. From the remains still existing, however, there would seem to have been large open-air theatres at an early age in England. Of these, Piran Round in Cornwall is the best example. It is circular, with raised platforms all round for spectators, after the manner of the Greek theatres. With the revival of classical literature in the 16th c., the classical drama was also reproduced, and naturally along with it the classical form of theatre. The first specimens of what may be called modern theatres (although founded on the old Greek model, according to Vitruvius's description) were the Theatro Olympico, erected by Palladio in Vicenza; a similar one in Venice, also by Palladio; and another in Vicenza, by Serlio. In Italy and Spain, open courtyards, with galleries round them, were at first the scenes of dramatic performances. In France and England, where the climate did not so readily admit of open-air representations, the first plays performed were exhibited in tennis or racket courts, in which there were usually galleries at one end; and as this accommodation was found too limited, these were afterwards carried along the sides also. But dramatic literature soon became so important that buildings had to be designed for the express purpose of its representation. Accordingly, in Paris, the theatre of the Hôtel de Bourgogne was erected in the beginning of the 17th century. It was rebuilt, 1645, with tiers of boxes on a square plan. In 1639, the theatre of the Palais Royal was erected by Richelieu, and was long considered the best model. The present circular plan of the galleries, with pit sloping backwards, seems to have been first introduced in Venice in 1639; and the horse-shoe form of the boxes was first carried out by Fontana in the Tordinoni Theatre, at Rome, in 1675. The modern form of the auditorium was thus invented, and gradually improved and perfected, till in about a century similar theatres were erected all over Europe; the Scala Theatre at Milan, the largest in Italy, and the great theatre at Bordeaux, being built, the former in 1774, and the latter in 1777. The annexed plan of the Scala Theatre at Milan (fig. 2), will shew the general disposition of all the parts of the modern theatre on the largest scale. Modern theatres are all very similar in their general distribution. They are divided into two distinct departments—viz., the auditorium or audience department, and the stage or scenic department. In the former, the seats are invariably arranged on a sloping ground-floor or 'pit;' and on several tiers of galleries, extending in a semicircular or horse-shoe form round the house. On the ground-floor, the front rows of seats are generally set apart as 'dress stalls,' and the back part only is then called the 'pit.' In opera-houses, the stalls generally occupy the greater portion of the space, and the 'pit' is reduced to a minimum. In dramatic theatres, the tiers of galleries have the floors arranged in stages, rising above one another in such a manner as to enable the spectators all to see over those before them to the front of the stage. In theatres for operatic representation, the galleries have the floors laid level, and are divided all round into private boxes. The top tier is, however, sometimes left partially open, and has the seats on stages. In the larger opera-houses, there are usually retiring-rooms connected with each of the private boxes. There is also a 'crush-room,' or large saloon, in which the audience may promenade between the acts. In all French theatres and opera-houses, these saloons, or *foyers*, are very large, and elegantly fitted up. They are almost always over the entrance-hall. In some of the modern French theatres, there are two foyers, one over the other, for the different classes who occupy the dress circle and the upper galleries. The question has often been raised as to the best form for a theatre, both for hearing and seeing. It is a most difficult question to decide theoretically as regards hearing, but it is quite clear that the old semicircular plan of the Greeks is as nearly as possible the best for seeing, as it places the seats all round at an equal distance from the centre of the proscenium; and therefore we find, in cases where seeing well is all-important, as, for instance, in a *lecture theatre*, this old form is usually adopted. In an oblong house, on the other hand, the seats at the centre of the galleries are much further removed than those at the sides from the centre of the stage, and are thus at a disadvantage as regards hearing; while the side boxes are badly placed for commanding a view of the stage. The entrances and staircases of theatres are not generally so well arranged or so spacious as they should be. In French theatres, this is especially the case. In these, there is often only one narrow wooden stair on each side of the house, leading to all the galleries. Recent accidents by fire, and the risk the audience runs in case of want of proper

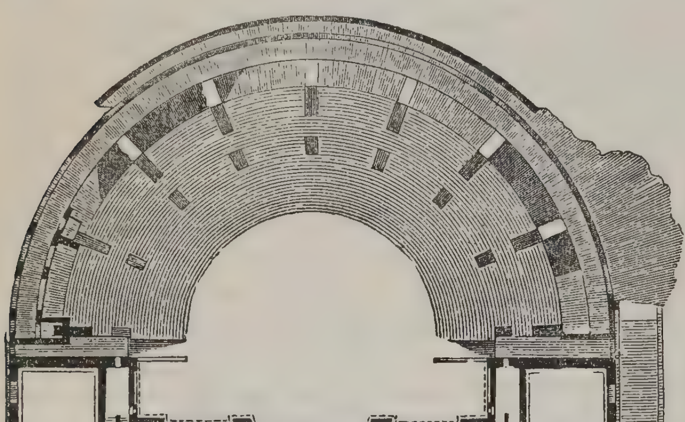

Fig. 1.—Plan of the Theatre at Orange—scale, 100 feet = 1 inch.
(From Ferguson.)

exits, have drawn attention to this subject, and the legislature will probably determine that there must be a separate, wide, and easy stair to each gallery —as, indeed, there usually now is in theatres recently built in Great Britain. For large galleries, these stairs should be at least six feet wide; and a strong iron hand-rail down each side of the stair would be found useful in case of a panic, to prevent a fatal crush. Besides the main passages for the use of the public, there ought to be private passages and doors leading to every part of the house, so that the manager may pass with ease to any point in the audience where his presence may be required.

The orchestra occupies the space immediately in front of the proscenium, and this space is arranged so as to be capable of being enlarged or contracted as occasion may require. The proscenium is a small portion of the stage which projects a few feet in front of the curtain, so as to enable the actors to stand well forward, that they may be distinctly heard by the audience. The part of the house on either side of the proscenium is that on which there is usually the greatest amount of ornament. The sides

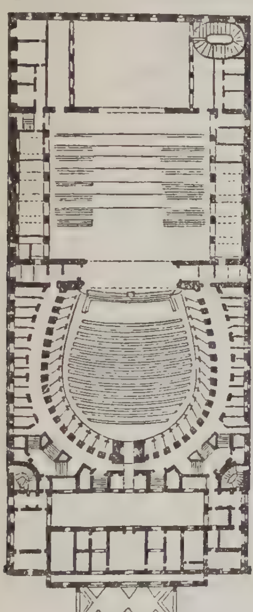

Fig. 2.—Plan of La Scala Theatre at Milan—scale, 100 feet = 1 inch.

(From Ferguson.)

and ceiling of the proscenium form, as it were, the frame through which the picture represented on the stage is seen; and as on it every eye must rest, it is made more ornate than the rest of the auditorium. The ceiling presenting as it does a large broad surface, and being well seen from many parts of the house, is also a place well adapted for ornament, and is generally made as handsome as possible. The same remark applies to the fronts of the dress circle and galleries. The stage extends backwards from the proscenium, and ought to be of considerable depth, so as to admit of the scenic effects, dissolving scenes, &c., now so much run upon. The great length of the stage from front to back is one of the most striking differences between the modern and the ancient theatre, and arises entirely from the introduction and development of movable scenery —an invention of the architect Baldassare Peruzzi, and first used in Rome before Leo X., in 1508. The floor of the stage is not laid level like the floor of a room, but is sloped upwards from front to back, so as to elevate the performers and scenes at the back, and render them more easily seen. The inclination of the stage is generally about half an inch to every foot. The stage department of a theatre not only requires to be very long, but also very lofty above, and deep below the stage, so as to allow the large frames on which the scenes are stretched to be raised or lowered in one piece. The stage itself is a most complicated piece of mechanism, a considerable part of it being made movable either in the form of *traps*, for raising or lowering actors, furniture, &c., or in long pieces, which slide off to each side from the centre, to allow the scenes to rise or descend. There are also *bridges*, or platforms constructed for raising and lowering through similar openings, some of them the full width of the stage. The traps and bridges are almost all worked by means of balance-weights, and the slides by ropes and windlasses. Besides the large *frames* above described as containing pictures occupying the full opening of the stage, there are other scenes which are pushed from the sides to the centre, each being only one half the width of the opening. These are called *flats*, and usually slide in grooves above and below. The grooves are arranged in clusters at intervals, having clear spaces between, called the *entrances*, through which the actors pass on and off the stage. But in modern French theatres and in the opera-houses—such, for instance, as Covent Garden Theatre these grooves are regarded as an encumbrance to the stage, and are entirely done away with. Their place is occupied by narrow openings or slits in the stage, below which are blocks running on wheels, and containing sockets, into which poles are dropped from above, and to these the flats are attached. Another advantage of this system is, that the gas-wings and ladders may be made movable, and slip backwards and forwards in the same manner as the flats. When occasion requires, the whole stage can thus be entirely cleared. According to the old plan of fixed grooves, only the centre of the stage can ever be cleared without unscrewing all the grooves, and the gas-wings must always remain in the same relative position. Besides the flats, there are also smaller scenes which move in the grooves. These are called *wings*, and are used to screen the entrance. Corresponding to the wings are similar narrow scenes dropped from above: these are called *borders*, and are used to hide the gas-battens. These and the scenes which are drawn up, the gas-battens, &c., are all worked by means of ropes from the *flies*, or galleries running along the sides of the stage at a high level. The ropes from these passing up into the barrel-loft (a space in the roof filled with large drums and barrels on which the ropes are coiled) and down again to the flies, form a complication which seems to the uninitiated observer an inextricable mass of confusion. While such is the usual arrangement connected with movable scenery, it is to be noted that latterly a very great change has been introduced into the higher class of theatres. This change consists in the dismissal of wings or sliding side portions of scenes with intervening gaps, and substituting for them large pieces of scenery resembling the sides and further ends of a room—an arrangement every way more natural. In cases of this improved kind, the actors enter on the stage and depart by doors. In connection with the stage, it is usual to have a large space set apart for containing scenery, called the *scene-dock*

This is frequently placed at the back of the stage, and may, on occasion, be cleared out, to give extra depth to the scene. There are also numerous apartments required in connection with the stage for the working of the theatre—such as manager's room; dressing-rooms for the actors and actresses; the 'green-room,' in which they assemble when dressed, and wait till they are called; 'star-rooms,' or dressing-rooms for the stars; the wardrobe, in which the costumes are kept; furniture stores, scene stores; 'property'-maker's room; and workshops for the carpenter, gas-man, &c. There must also be a good painting-room, which must necessarily be a large apartment, from the size of the pictures which have to be painted — each being the full size of the opening of the stage. The canvas for these scenes is stretched on frames, which move up and down by means of a winch with balance-weights; and thus the painter stands comfortably on the floor, and moves his picture up or down, so as to get at any part he wishes. An interesting point on the stage is the prompt corner, from which the prompter has command of all the lights of the house, and bells to warn every man of his duty at the proper moment. He has a large brass plate, in which a number of handles are fixed, with an index to each, marking the high, low, &c., of the lights; and as each system of lights has a separate main pipe from the prompt corner, each can be managed independently. The side of the house on which the prompter is seated is called the 'prompt side,' and the other side is called the 'O. P.' or *opposite* side.

The house, or auditorium department, is generally lighted by means of a large lustre or sun-light in the centre of the ceiling, and much of the effect of the building depends on how this is managed. There are also usually smaller lights round one tier of the boxes at least. The proscenium is lighted by a large lustre on each side, and by the foot-lights, which run along the whole of the front of the stage. These are sometimes provided with glasses of different colours, called mediums, which are used for throwing a red, green, or white light on the stage, as may be required. The stage is lighted by rows of gas-burners up each side and across the top at every entrance. The side-lights are called *gas-wings*, or *ladders;* and the top ones, *gas-battens.* Each of these has a main from the prompt corner. They can be pushed in and out, or up and down, like the scenery. There is also provision at each entrance for fixing flexible hose and temporary lights, so as to produce a bright effect wherever required. The mediums for producing coloured light in this case are blinds of coloured cloth. Another means of producing brilliant effects of light is the lime-light, by which, together with lenses of coloured glass, bright lights of any colour can be thrown on the stage or scenery when required.

Theatres are usually either very cold or insufferably hot. This arises from want of proper means of heating, and insufficient ventilation. The centre lustre is the great cause of ventilation, the draught caused by its heat drawing off the foul air at the ceiling. The suction caused by this withdrawal of air is naturally supplied from the great body of air in the stage. The stage ought, therefore, to be moderately heated by means of hot-water pipes or otherwise, so as to prevent cold draughts. The passages and lobbies round the house should also be heated in the same way, so that any air drawn in to the house may be properly tempered. An attempt has been made in Paris, of late years, to obviate the great heat and draught caused by the centre lustre, by doing away with the lustre, and making the ceiling partly of glass, with powerful lights and reflectors behind the glass in the roof. This mode of lighting is, however, of rather a subdued character for a theatre, although very appropriate to such chambers as the House of Commons, where it acts admirably. In Paris, they have also tried to supply fresh air from the gardens outside by means of a large tube, from which numerous small tubes branch and distribute the fresh air all round the theatre from the fronts of the boxes, round the proscenium, &c. The idea is an excellent one, and is said to answer well practically.

There is a novel and agreeable class of theatres now in use in Germany, but of which we have as yet no specimens in this country. It consists of a double auditory, one at each end of the stage. One of these auditories is arranged and lighted in the usual manner, and is called the Winter Theatre. The other auditory is called the Summer Theatre, and is so arranged that performances may be represented in daylight during the summer season. It is lighted by large windows in the outer wall, which corresponds in form to the interior curves of the galleries, and also by windows in the roof. The entrances are by means of staircases at each side, near the proscenium, and by wide corridors and balconies round the curve of the exterior wall. One of the most effective of these summer-theatres is the Victoria in Berlin, by Zitz.

The art of *dramatic representation* has undergone great changes. In ancient Greece, partly from the character of the subjects selected, and partly from the origin of the drama itself, costume and acting were conventional, artificial, and stereotyped. On this point, we quote the words of Witzschel, who has written a Handbook for Students on the Athenian Stage (Eng. transl. by Paul; ed. by T. K. Arnold, Lond. 1850): 'There can be no doubt,' says he, 'that the somewhat fantastic costume which was handed down without any change from one generation of actors to another was closely connected with the religious character of their tragic performances. The peculiar fashion and brilliant colours of the tragic wardrobe belonged rather to the Dionysian solemnities than to the stage. That Æschylus, by whom the greater part of it was invented, kept steadily in view the original intention of tragedy, is evident from the notices which we find in ancient writers of his theatrical dresses having been worn in other religious ceremonies and processions. It is only reasonable to suppose that he would have given to the tragic stage a wardrobe of a very different description, had he not been influenced by the conviction, that theatrical performances were in some sort a religious ceremonial. Another proof of the feeling generally entertained on this subject may be found in the ridicule with which Aristophanes overwhelms Euripides for introducing his heroes, not only in pitiable situations, but in dirty, ragged, and beggarly weeds, to the great disgust of all true-hearted Athenians, and the utter annihilation of tragic ideality. In the *Acharnenses*, the whole of the tragic poet's squalid wardrobe is held up to public derision.

'The tragic costume for male characters of the highest rank consisted of an embroidered tunic with sleeves, which, in the older personages, reached to the feet (*chiton poderes*), and in the younger to the knees. Over this was thrown a green pall, or long mantle (Gr. *surma*, Lat. *palla*), which also reached to the feet, and was richly ornamented with a purple and gold border. Persons of high but not royal rank wore a shorter red mantle, embroidered with gold, which was partially covered by a richly-embroidered, high-fitting scarf. Soothsayers wore over the tunic a kind of network, composed of woollen threads. A sort of waistcoat

(*kolpōma*) was also worn over the tunic. This was the costume of powerful and warlike sovereigns, such as Atreus, Agamemnon, &c. Dionysus (Bacchus) appeared in a purple tunic, which hung negligently from an embroidered shoulder-knot, and a thin, transparent, saffron-coloured upper robe, with a thyrsus in his hand. Even Hercules himself was not the athletic hero of the old mythology, with a lion's skin thrown loosely round his muscular limbs, but a solemn, theatrical personage, enveloped in a long mantle. The costume of a queen was a flowing purple robe, with a white scarf; and for mourning, a black robe, and blue or dark yellow shawl. Persons in distress, especially exiles, wore dirty-white, dark-gray, dingy-yellow, or bluish garments. . . . . To increase their height, the tragic performers wore the cothurnus, a sort of buskin, with high soles and still higher heels, which compelled them to walk with a measured and sounding tread, and a top-knot of hair, or toupet (Gr. *ongkos*), suitable to the age and condition of the character represented. A corresponding breadth of figure was produced by means of padding and by a sort of glove. Thus equipped, the tragic hero seemed a giant as compared with ordinary mortals. Lastly, they had the mask, a part of the ancient theatrical costume, which seems to us so strange and unnatural. For its meaning and origin, we must go back to the Dionysian festival, at which the excited crowd were wont, in honour of the jolly god, to smear their faces with lees of wine; and at a later period, when dramatic interludes were attempted, with vermilion, or to cover their cheeks with rude masks of bark. In the course of time, these primitive inventions were discarded, and their place supplied by linen masks, characteristically painted. For the sake of retaining this uncouth but distinctive appendage of the Dionysian festival, the Greeks were content to forego the delicate expression of feeling and eloquent play of features which are indispensable to a modern actor; but on the other hand, when we remember the enormous size of their theatres, which scarcely permitted the assembled thousands to hear what was said by the actors, still less to distinguish their features, we are forced to acknowledge that the practice of wearing masks was rather an advantage than an inconvenience.' The above description is, in the main, applicable to the Roman as well as the Greek theatres. The only additional point which it is necessary to notice is that, among the ancients, the acting of plays was not (as it is now) a regular and daily, but only an occasional affair, at festival seasons and the like. With the fall of the Western Empire, the disappearance of classic paganism and classic tastes, and the triumph of the christianised barbarians of the north and east, theatrical performances ceased. But the liking for such things is not artificial; it is natural and irrepressible; and gradually, as the ancient culture resumed something of its former sway, efforts were made, not, indeed, to re-enact the majestic tragedy of Greece (for its language was scarcely known), or the pungent comedy of Rome, but to throw into dramatic form the 'mysteries,' 'miracles,' and 'moralities' of the Christian religion. The rudeness of these medieval plays may perhaps suggest to us what Greek performances were before the days of Thespis. In fact, they were introduced as a means of edifying, as much as of amusing the ignorant laity, were customarily the work of monks, and were performed on festive occasions in the churches. It does not, however, appear that they were accompanied by any *scenic* representations. A raised wooden stage like that which forms the front of a travelling show, was all that the untutored taste of the times demanded. Nor are we to suppose for a moment that the slightest attention was paid to propriety of costume or speech. The personages rather than the actions, the ceremony rather than the dialogue, the moral rather than the matter, were the things looked to, and hence no subtle or artistic representation of life and character was possible. The development of the Modern Drama (q. v.) ultimately restored the art of the actor to its ancient dignity and importance; but it was long before those changes took place that gave theatrical performances their modern character. Good acting—that is to say, skilful impersonation of character and varied elocution—became quite common in England after the Restoration, and was not unknown before it; but appropriate costume and scenery were scarcely thought of until the time of Talma (q. v.), towards the close of last century. Since then, the best theatres have displayed a most creditable desire to reproduce, with something like verisimilitude, the outward 'form and pressure,' the garb, deportment, and air of the age represented.

The employment of female actors is of French origin, and dates from the first half of the 17th c.; but they were not permitted (without molestation) to tread the English stage till 1661. Before this innovation, female parts were performed by youths; and though it ill consorts with *our* ideas of adequate representation to conceive the parts of Desdemona Ophelia, Cordelia, &c., executed by those of another sex, it would appear that several actors obtained a wonderful success in this line.

The title of 'His Majesty's Servants,' which English actors once bore, originated in the fact that some of them were really members of the royal household. The king and particular nobles kept troops of actors for their own pleasure, whom they sometimes permitted to go about the country and perform. The first prince we read of that gave his 'servants' such permission, was Richard, Duke of Gloucester (afterwards Richard III.). In Queen Elizabeth's time (1571), the Earl of Leicester's 'servants' were licensed to open the first *public* theatre in England, and it is owing to the circumstance of actors having originally formed part of the household of the king that a licence from the Lord Chamberlain is still necessary to the opening of a theatre.

For an anecdotical and amusing history of the English stage, see *Their Majesties' Servants*, by Dr Doran (Lond. 1865).

THEATRES, LAWS AS TO. In Great Britain, all theatres must be licensed, either by virtue of letters patent from Her Majesty, or by licence from the Lord Chamberlain for the time being, or from justices of the peace. The Lord Chamberlain grants licences to all theatres (not being patent theatres) within the English metropolis, and within the places where Her Majesty occasionally resides, except New Windsor and Brighton. For every licence of the Lord Chamberlain, a fee not exceeding 10s. per month is charged. In other parts of Great Britain, the justices of the peace of the county, city, or borough must be applied to for a licence; and after the usual notice, they hold a special session, for the purpose of granting licences to theatres, the fee payable being a sum not exceeding 5s. per month. It is only to the actual and responsible manager of the theatre that a licence can be granted, and his name and place of abode must be printed on every play-bill. The manager must find sureties to observe the rules issued by the Lord Chamberlain and justices, which rules relate to the days and hours of keeping open. and the insuring of order and decency. A penalty of £10 is imposed, by statute 6 and 7 Vict. c. 68, on any actor or manager concerned in unlicensed places

A copy of every new play, epilogue, or prologue, or alteration of the same, intended to be produced at any theatre in Great Britain, must be sent to the Lord Chamberlain, by the manager, seven days before such production; and for examination of such plays and alterations of plays, he may charge fees not exceeding ten guineas, according to a scale fixed by him. He may forbid the acting of any play, whenever he considers it to be fitting to the preservation of good manners, decorum, or the public peace, to do so. To act a play not allowed or disallowed, subjects each actor and manager to a penalty of £50. It has been decided by the courts, that a booth used as a temporary or portable theatre requires a licence, and that any dualogue or dramatic performance by two persons is a stage-play, and therefore subject to the licence. Of late, the policy of placing the theatres so entirely under the control of the Lord Chamberlain and justices has been disputed, especially as the increasing practice of introducing theatrical performances at public supper-rooms has led to some vexatious prosecutions at the instance of the licensees of regular theatres.

THE'BAINE. See OPIUM.

THEBES, the name of a celebrated Egyptian city, called by the Egyptians Taape, or Taouab; by the Hebrews, No-Amen; by the Greeks, Thebæ; and at a later period, Diospolis Magna. It lies in the broadest section of the valley of the Nile, in about lat. 26° N., and was formerly the capital of Southern or Upper Egypt. Its ruins, the most extensive in that country, comprise nine townships, the most remarkable of which are Medinat Habu, Gournah, Karnak, and Luxor. Its local and eponymous god was Amen-Ra, or Jupiter Ammon; and its foundation traditionally dated from the time of Menes, the founder of the monarchy, although no remains of so early a date have been discovered on the site. Recently, however, excavations have brought to light constructions of the 11th dynasty, who appear to have founded the original temple of the god. The Nile flows through the midst of the ancient city, and divides it into four principal quarters: Karnak and Luxor, which lie on the east bank, and Gournah and Medinat Habu, on the west bank of the river. The most flourishing period of the city was under the 18th, 19th, and 20th dynasties, or from about 1500 to 1000 B.C., when it had supplanted Memphis, the ancient capital of the Pharaohs. The more central situation of this city probably caused it to rise into importance, for it was secure against the northern enemies of Egypt; hence, under these Diospolitan dynasties, the worship of Amen-Ra arose in all its splendour; magnificent palaces and temples were built in its different quarters, to which additions were made by later monarchs, and even by the Ptolemies and Romans till the time of the Antonines, in the 2d C. A.D. Here, too, were the cemeteries of the Theban monarchs and the officers of their courts, colleges of priests, and the seat of royal government. It was enriched by the spoils of Asia and the tributes of Ethiopia, and its fame and reputation had reached the early Greeks, Homer describing it by the epithet of Hekatompylos, or City of a Hundred Gates, in allusion to its propylæa, for T. was never a fortified city. In the plenitude of its power, it sent forth an army of 20,000 war-chariots; but the Bubastite and Tanite dynasties removed the capital again to Sais and Memphis, and T. declined in importance, although retaining much of its ancient grandeur. At the Persian conquest, Cambyses obtained a spoil of nearly £2,000,000 from the city, destroyed many of its noblest monuments, and injured its political pre-eminence. The foundation of Alexandria by Alexander the Great, and other causes, still further injured the city; and although some repairs were made under the subsequent monarchs, its grandeur had departed. At the time of Strabo, T. was only a cluster of small villages. When that geographer visited the city, its extent was about 9½ miles in length (according to Diodorus), its circuit was about 16 miles. Its temples, tombs, and ruins were visited by the Roman travellers; and Germanicus and Hadrian inspected the sculptures of the temples. At a later period, a considerable Christian population existed under the empire; but the inhabitants fled at the Arab invasion to Esneh; and T. is now inhabited only by a few Arab families of Fellaheen, who obtain a precarious livelihood by guiding travellers over the ruins, or rifling the tombs for antiquities. At Gournah, is to be seen the Memnoneion, built by Ramesses II.; with a colossus of that monarch, weighing 887½ tons, the largest statue in Egypt, broken. This is supposed to be the palace of Osymandyas, described by Hecatæus, and is of considerable extent. In this quarter are two palace-temples of Amenophis III., and the vocal Memnon, or celebrated colossus of that monarch, supposed by the ancients to emit a sound at sunrise. At Medinat Habu is a pile of buildings, commenced by Thothmes I., of the 18th dynasty, with courts and propylæa, built by Ramesses III. or Rhampsinitus, and sculptures representing his victories over the Philistines, the life in his harem, the riches of his treasury, and a calendar with inscriptions dated in the twelfth year of his reign. Here, 8000 feet to the north-west, are the cemeteries of sacred apes; and 3000 feet beyond, the valley of the Tombs of the Queens, consisting of 17 *syringes*, or sepulchres, supposed to be the tombs of the Pallacides of Amen, mentioned by Diodorus and Strabo. Near them are the Biban-el-Meluk, or tombs of the monarchs of the 19th and 20th dynasties, 16 in number, the most interesting of which are that of Sethos I., called Belzoni's, after its discoverer, and those of Ramesses III. and Siptah. At Gournah itself are the tombs of functionaries and others, and this latter site has enriched the museums of Europe with antiquities of various kinds. The palaces of the Luxor quarter were founded by Amenophis III. From hence was removed the obelisk of the Place de la Concorde in Paris. Still more magnificent than any of these is the temple of Karnak, the sanctuary of which, built by Osertesen I. of the 12th dynasty, was added to by the monarchs of the 18th dynasty. The most remarkable part of this wonderful mass of courts, propylæa, and obelisks, is the great hall, 170 feet by 329 feet, built by Sethos I. and Ramesses II., having a central avenue of 12 massive columns, 66 feet high, 12 feet in diameter; and 122 other columns, 49 feet 9 inches high, 27 feet 6 inches in circumference; and 2 obelisks, 92 feet high, and 8 feet square. In this temple is also the so-called Portico of the Bubastites, built by Shishak I., recording his expedition against Jerusalem, 971 B.C. The Ptolemies also restored this building.—Diodorus, i. 45; Strabo, xvi. p. 816; Wilkinson, *Topography of Thebes* (8vo, Lond. 1835); Champollion, *L'Egypte*, i. p. 199, and foll.; *Lettres*, pp. 63—173; Belzoni, p. 58.

THEBES, the principal city of Bœotia, in ancient Greece, was situated in the southern part of th country, on the slopes of Mount Teumessus, and between two streams, the Dirce and the Ismenus. According to the prevalent tradition, T. was founded by a colony of Phœnicians under Cadmus (q. v.), after whom the city was called Cadmeia—a name subsequently restricted to the citadel; but passing over the long series of picturesque and tragic myths that

have given it its pre-historic fame (in which the central figure is Œdipus), we first catch a quasi-authentic glimpse of Theban history in the 8th c. B.C., when one Philolaus, a Corinthian, settled in the place, and drew up a code of laws for the inhabitants. It is not till near the end of the 6th c. B.C., however, that we reach a purely historical period—the earliest well-attested event being the dispute between T. and another Bœotian city, Platææ, which involved the former city in an unsuccessful war with Athens. Henceforth, the relations of T. and Athens were, except for brief intervals, marked by bitter enmity. During the Persian war, T. shamefully sided with the Asiatic invader, and, in consequence, lost much of her power and prestige. Athens proposed to deprive her of her supremacy over the Bœotian confederacy; but Sparta, always jealous, even to spitefulness, of her Attic rival, interfered, and positively forced the other Bœotian cities to acknowledge anew their unworthy mistress. When the Peloponnesian war broke out, T. took part with Sparta, and at its close, was eager for the destruction of Athens; but soon after, it became jealous of the overgrown power of its ally, and gave a friendly welcome and shelter to those Athenians whom the oppression of the Thirty Tyrants (q. v.) compelled to abandon their city. It was from T. that Thrasybulus and his co-patriots started on their famous expedition for the deliverance of Athens, accompanied by a body of Theban citizens. A keen and bitter antagonism now sprung up between T. and Sparta, which, after many vicissitudes, ended in a great military struggle (379—362 B.C.), in which the former city, under the heroic guidance of Epaminondas (q. v.), achieved a brilliant triumph, and for a time held the position of the foremost power in Greece. It was now the time for Athens to revive her ancient animosities; and for a while they had free play. At length, the eloquence of Demosthenes induced both states to unite in opposition to the encroachments of Philip of Macedon; but it was too late; and in 338 B.C., the battle of Chæroneia crushed the liberties of Greece. After Philip's death, the Thebans made a fierce but unsuccessful effort to regain their freedom. Their city was taken by Alexander, who levelled it to the ground, and sold the entire population—men, women, and children—into slavery. For 20 years it remained an utter desolation; but in 315 B.C. it was rebuilt by Cassander, who gathered into it all the Thebans he could find in Greece. It was again destroyed by the Romans, and did not recover till about the decline of the empire. During the 11th and 12th centuries, it was the seat of a considerable population, engaged in the manufacture of silk; but under the Turks it again declined, though it has still a modern representative, Thebes, or Thiva, with a pop. of 9000. Scarcely a single relic of antiquity has survived the ravages of time.

THE'CLA, a virgin saint of the early church, whose existence may be considered historical, although all, or almost all, the details regarding her are legendary, being in great measure founded upon an apocryphal book, now lost, entitled *The Periods (circuits) of Paul and Thecla*, the unhistorical character of which is declared by Tertullian (*De Bapt.* ii. 17), and by St Jerome in his catalogue of ecclesiastical writers. According to the legend, T. was a member of a noble family of Iconium in Lycaonia, where she was converted by the preaching of St Paul, and having devoted herself to a life of virginity, suffered a series of persecutions from her intended bridegroom, as well as from her parents. As to the manner of her death, nothing is certain. She is styled in the Greek martyrologies the *proto-martyress*, as Stephen is the proto-martyr; while in the Roman Breviary, she is said to have died at the age of 90 in Seleucia, where her tomb was anciently pointed out. The *Acts of Paul and Thecla* was among the books stigmatised as 'apocryphal' by Pope Gelasius: but it is now lost.

THE'INE. See CAFFEINE and TEA.

THEISS, an important affluent of the Danube, and the chief river of Hungary, rises by two streams, the Black T. and the White T., in the Carpathian Mountains, on the borders of Galicia. It flows first south through a mountain-pass; but after receiving the Viso from the south-east, it changes its course to north-west and south-west, flowing past Tokay to Szolnok, where it curves toward the south; and after running parallel to the Danube for upwards of 300 miles, it joins that river about 5 miles below the town of Titel. The principal towns upon its banks are Szigeth—about 50 miles from its source—Tokay, Szolnok, Csongrad, and Szegedin; and its chief affluents are, on the right, the Vorsova, Bodrog, and Hernad; on the left, the Szamos, Körös, Maros, and Bego, and of these the most are of considerable size, and navigable. The T. is navigable at Szegeth for small vessels, at Nameny for steamers, and at Szolnok for large vessels. At Szöllös, it enters upon the plain, and below this point, its fall is trifling, its course sluggish and very winding, and its banks low and marshy. At Tokay, it is 300 feet broad; at Szegedin, 400 feet; and at Titel, 740 feet. Its length, in direct line from source to mouth, is 280 miles; the entire length, including windings, is 828 miles.

THELUSSON ACT is an act of parliament, 39 and 40 Geo. III. c. 98, passed for the purpose of checking the disposition of testators to accumulate the income of their estates until they should form a large fortune. The late Mr Thelusson had, by his will, directed his personal property to be invested in land, and the rents and profits of the land to be so purchased, and of his other real estate, to be accumulated during the lives of all his descendants who should be living at the time of his death, or born in a certain time thereafter; and then he limited the accumulated property in favour of certain of his descendants who might be then living at that distant time. The property was said to have consisted of landed estates worth £4000 a year, besides personalty of about half a million; and it was estimated that the accumulated fund would amount to above nineteen millions. The testator's object was to create enormous wealth, for the purpose of founding three families to spring from his three sons. For half a century, the questions arising out of this will have been discussed in various forms; but the legislature, soon after the testator's death, took the earliest opportunity of preventing in future testators accumulating the income in this way for more than 21 years, and the above act was passed for that purpose. In the courts, the first attempt to upset the will of Mr Thelusson was to make out that it was too uncertain to be carried into execution—next, that the accumulation was illegal—next, whether males claiming through females would be entitled to a share: all of which attempts to upset the will failed. Ultimately, however, the fund proved not to be so large as was anticipated, and was distributed among a greater number of claimants. The eldest son was created Baron Rendlesham in 1806. The litigation ended by a decree of the House of Lords in 1858. The Thelusson Act has been extended to Scotland.

THE'MIS (Gr. 'what is established by old law'), in Greek Mythology, was the daughter of Uranus and Gē (Heaven and Earth), the wife of Zeus, and

by him, mother of the Horæ (Hours) and Mœræ (Fates), as also of Eunomia (Equity), Dikē (Justice), and Eirēnē (Peace). She was regarded as the personification of order and justice, or of whatever is established by 'use and wont;' and as such was charged by Zeus to convoke the gods, and preside over them when assembled, being likewise represented as reigning in the assemblies of men. In modern art, T. is represented as having her eyes bandaged, and at the same time holding a pair of evenly-balanced scales in one hand, with a sword in the other.

THEMI'STOCLES, the great Athenian general and statesman, was the son of an obscure citizen of Athens, and was born about 514 B.C. He was actuated by excessive ambition from a very early period, and began his public career by setting himself in opposition to the principal men of the state, and chiefly Aristides, 'the Just.' It is uncertain whether he was at Marathon, but there is no doubt that the laurels gained there by Miltiades fired T.'s ambition. From the time (483) that he got his inconveniently upright rival, Aristides (q. v.), ostracised, he was regarded as the political leader in Athens, being made Archon Eponymus in 481. In order to recover for Athens the naval supremacy in Greece, and that she might be prepared to meet the expected Persian invasion, he persuaded the Athenians to devote the proceeds arising from the silver mines at Laurium to the construction of a fleet, sagaciously foreseeing that his country's only chance of overcoming her enemy was by sea. In the battles of Artemisium and Salamis (480), disastrous for the Persians, T., commander of the Athenian fleet, the largest in Greece, to avoid dissensions, was content to serve under Eurybiades the Spartan. On both these occasions, it was only by the greatest tact, combined with threats and a judicious outlay of the bribes which he himself had received in profusion, that T. could induce the other commanders to come to an engagement with the Persians. On the night previous to Salamis, he sent a faithful slave to tell Xerxes that unless he came up next day, the Greek fleet would be scattered, and he would miss the chance of an engagement; thus securing either victory to the Greeks, or the favour of Xerxes to himself in case of defeat. See SALAMIS. In several other ways did the wily T. contrive to provide for himself a safe retreat at the Persian court in case of disaster. The victory at Salamis raised his reputation to the highest point. Not neglecting his own personal aggrandisement, he sailed round among the Grecian islands, and on various pretexts, extorted enormous sums from the inhabitants. Shortly after the Persian invasion, his fellow-citizens began to see through him, and he was accused of bribery and extortion. In 471, he was ostracised, and retired to Argos; and finally, to escape being tried for treason, in which he was implicated by the correspondence of Pausanias, he betook himself, in 465, to the court of Artaxerxes, king of Persia; but before he would see the king himself, got permission to wait a year, during which he made himself master of the language and usages of Persia. At the end of this time, he managed to raise himself so highly in the king's favour, that, after the Persian fashion, the town of Magnesia was appointed to supply him with bread, Lampsacus with wine, and Myus with other provisions. He lived securely at Magnesia until his death in 449. Some authorities assert that he poisoned himself. A monument was erected to T. in the market-place of Magnesia, and it is said that his bones were secretly taken to Attica, and burned there. Undoubtedly, T. was a man of very great sagacity and determination, had a quick and keen perception of difficulties both present and future, which his ready invention, backed by promptness of action, enabled him to meet and overcome. On the other hand, he appears to have been possessed of no moral principles, his greatest ambition apparently having been to make himself, by fair means or foul, the greatest man in Greece.

THE'NARD'S BLUE. See BLUE.

THEOBALD, LEWIS, was the son of an attorney at Sittingbourne in Kent, at which place he was born towards the close of the 17th century. His father's business, for which he was educated, proved not much to his mind; and betaking himself to literature, he published, in 1714, a tragedy entitled *Electra*, which he followed up by a number of other dramas. As a poet, he had scant success, and is long since utterly forgotten; but as the favourite butt of Pope, he is immortalised in the *Dunciad* of that writer. Besides this unenviable distinction, 'piddling Theobald,' as Pope contemptuously termed him, is not without some fair claim to be honourably remembered as one of the most laborious and useful of the early editors and commentators on Shakspeare. In this capacity, dull as he undoubtedly was, he did good service to the poet, which has since been sufficiently recognised. The hatred of Pope he incurred by a pamphlet published in 1726, entitled *Shakspeare Restored, or Specimens of Blunders committed or unamended in Pope's Edition of this Poet;* and if he could not compete with his adversary in wit, he proved himself a much more competent editor of Shakspeare by his edition in 7 volumes 8vo, published in 1733, which quite extinguished that of his rival. His knowledge of our earlier drama was extensive and minute; and to his judicious application of it, in elucidating the text of the great poet, we remain to this hour not a little indebted. He died in September 1744.

THEOBRO'MINE ($C_7H_8N_4O_2$) is a crystallisable principle present in chocolate. It is extracted from the cacao-nuts (the seeds of *Theobroma cacao*) in the same manner as caffeine or theine is extracted from the coffee, tea, &c., in which that substance occurs. It is less soluble in water than caffeine, but resembles that substance in forming crystallisable salts with some of the acids. By dissolving theobromine in a solution of ammonia, and adding nitrate of silver, a gelatinous precipitate is obtained, which, by boiling with a solution of ammonia, yields a crystalline mass of theobromide of silver ($C_7H_7AgN_4O_2$), in which 1 equivalent of hydrogen is replaced by 1 of silver. This compound, when treated with iodide of methyl, yields iodide of silver and caffeine, which latter may be extracted with alcohol. Hence we arrive at the remarkable conclusion, that caffeine ($C_8H_{10}N_4O_2$) must be regarded as methyl-theobromine, $C_7H_7(C_2H_3)N_4O_2$.

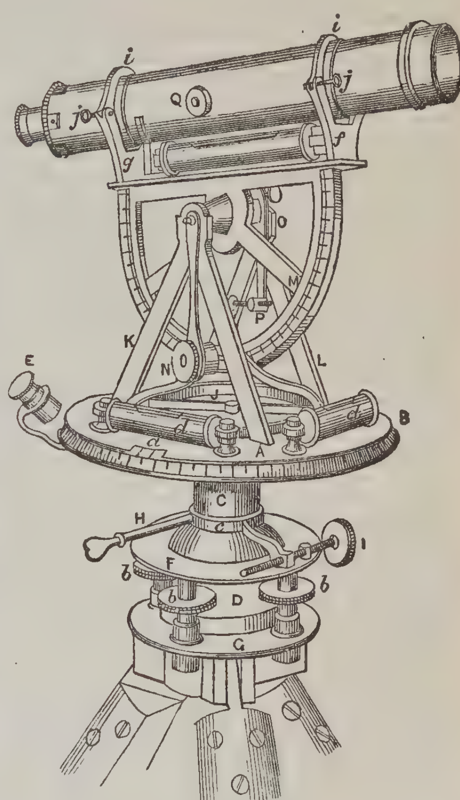
THEO'CRACY, literally, 'government by God,' is the name given to that constitution of a state in which the Almighty is regarded as the sole sovereign, and the laws of the realm as divine commands rather than human ordinances. Under such a view, the priesthood necessarily become the promulgators and interpreters of the 'divine commands,' and act as the officers of the invisible Ruler. The most famous example of a theocracy is that established by Moses among the Hebrews.

THEO'CRITUS, the creator and most celebrated composer of bucolic poetry, was the son of Praxagoras and Philinna, and born at Syracuse. The date of his birth is unknown, but the period o his greatest literary activity was probably 272 B.C. About the close of the reign of Ptolemy Soter, he visited Alexandria, where he received instruction

and made his first successful essays in poetry. He came to be patronised by Ptolemy Philadelphus, who assisted his father, Ptolemy Soter, in the government of Egypt; and in honour of his patron, he composed, about 285 B.C., his 14th, 15th, and 17th idyls. He further formed the acquaintance of the poet Aratus, to whom he addressed his 6th idyl. He subsequently revisited Syracuse, where he continued to reside under Hiero II. From his 16th idyl, it may be concluded that he was dissatisfied with the political state of Sicily, and also with the insufficient rewards which his poems received from Hiero; and that, in consequence, he fixed his attention, during his declining years, rather on the life of the country than of the court, and on those scenes of rural nature which form the chief subject of his poetical remains. The idyls of T. are principally representations, dramatic and mimetic in their character, of the every-day life of the Sicilian peasantry. They have been successfully imitated by Virgil, and have given origin at least to that so-called pastoral literature of medieval and modern times, which is, however, totally deficient in the simplicity, fidelity, and therefore poetry of the Syracusan author. T. knows nothing of the imaginary shepherds of a fictitious Arcadia; his dramatic simplicity and truth are in wide contrast to the affected sentiment, the unnatural innocence, and the artificial simplicity of that unreal world. Comedy and pathos enter freely into his representations of rural Sicilian life, and his idyls retain the charms of freshness and nature even to the present day. They are 30 in number, though all of them are not strictly bucolic, or even genuine. They are written in a mixed dialect, in which the softened Doric prevails; and together with a few lines from a lost poem called *Berenice*, and 22 epigrams in the Greek Anthology, make up his remains, of which the best editions are those of Meineke and Paley; and the best translation in English, that of Dr M. J. Chapman.

THEO'DICY (Gr. *Theos*, God, and *dike*, justice; Lat. *Theodicæa*, the judgment of God), a name given to the exposition of the theory of Divine Providence, with a view especially to the vindication of the attributes, and particularly of the sanctity and justice of God in establishing the present order of things, in which evil, moral as well as physical, so largely appears to prevail. The name is of modern origin, dating from the close of the 17th c., or the beginning of the 18th c.; but the theory itself, as well as the mysterious problem which it is meant to resolve, is as old as philosophy itself. See EVIL. The first to consider the question in its integrity was the celebrated Leibnitz (q. v.). His work entitled *Essais de Theodicée sur la Bonté de Dieu, la Liberté de l'Homme, et l'Origine du Mal*, was published in 1710. It rose at once to the very highest point of popularity, and was translated into almost every European language. The leading principle of Leibnitz's vindication of God's goodness is the well-known optimistic theory which has been explained elsewhere (see OPTIMISM); but he has been followed by several writers in different countries—as Balguy, Werdermann, Kinderater, Creutzer, Benedict Kapp, and many others. Of these writers, it may be said in general, that they have followed the same method, and have addressed themselves to the same view—viz., the reconciliation with the goodness, the sanctity, and the justice of the one God, the existence of those manifold evils, physical or material, as well as moral, which appear in the present order of things. This view, it will be seen, is strictly limited to one single problem. But in the discussions of the new philosophic systems, and especially that of Hegel, which have arisen in Germany, new difficulties regarding the Christian idea of God have arisen out of the rationalistic notions of existence in general. To meet those difficulties, a new theodicy has become necessary, and it has begun to occupy the attention of philosophers, especially in France. Two works in particular addressed to this view of the subject may be noticed: the first is M. Maret's *Christian Theodicée, or Comparison of the Christian and the Rationalistic idea of God*, 1845; the second is that of the Jesuit philosopher, Père Gratry, who has devoted the first volume of his course of philosophy, *De la Connaissance de Dieu*, to this special subject. This work was published at Paris, 1853.

THEO'DOLITE (Gr. *theaō*, I see, *dolichos*, long), an instrument much employed in land-surveying for



Theodolite:

A, B, the horizontal limbs; *a*, the vernier plate, which turns; C, the vertical axis; D, the ball or socket movement; *d*, *d*, spirit levels; E, a magnifier to read off the degrees; F, G, Plates held together by the ball D; *f*, a screw to adjust the level or line of collimation; *b*, *b*, *b*, milled screws to adjust the instrument, and set in level; *g*, a screw to adjust the telescope laterally; H, a clamping screw, by which means the collar *c* may be tightened to the axis C, and kept from moving; J, the magnet box; I, a slow-motion screw, by which the instrument is moved more exactly than could be done by the hand; *i*, *i*, clips, to reverse the telescope by screws, *j*, *j*; K, L, frames into which the pivots are placed, on which the vertical arc M is turned round, and on which the telescope is fixed; N, a microscope for reading off the degrees; O, a clamp screw; P, a slow-motion screw, by which the vertical arc and telescope are moved; Q, a milled screw for moving the object-glass of the telescope.—From Cresy's *Encyclopædia of Civil Engineering*.

the measurement of angles horizontal and vertical, is neither more nor less than an altitude and azimuth instrument, proportioned and constructed

so as to be conveniently portable. Like all instruments in very general use, the variations in its construction are almost numberless; but its main characteristics continue unaltered in all forms. It consists essentially of two concentric circular plates of copper, brass, or other material (the upper plate, or *upper horizontal*, either being smaller, and let into the lower, or *lower horizontal*, or the rim of the lower raised round the outside of the upper), moving round a common axis, which, being double, admits of one plate moving independently of the other. Upon the upper horizontal rise two supports, bearing a cross bar, which is the axis of a *vertical circle* moving in a plane at right angles to the former. This latter circle either has a telescope fixed concentric with itself, or a semicircle is substituted for the circle, and the telescope is laid above, and parallel to its diameter. The circles, as their names denote, are employed in the measurement of horizontal and vertical angles. For these purposes, the outer of the horizontal circles is graduated, and the inner carries the index-point and the Verniers (q. v.); the vertical circle is also graduated, and the graduations are generally read off by an index-point and vernier firmly attached to the supports. The upper horizontal is furnished with two levels placed at right angles to each other, for purposes of adjustment, and has a compass-box let into it at its centre. The stand consists of a circular plate supported on three legs, and connected with the lower horizontal by means of a ball-and-socket joint; the horizontal adjustment of the instrument being effected by means of three or four (the latter number is the better) upright screws placed at equal distances between the plates. The telescope is so fixed as to be reversible, and the adjustments are in great part similar to those of other telescopic instruments, but are too numerous and minute to be here detailed. Both horizontal plates being made, by means of the screws and levels, truly level, the telescope is pointed at one object, and the horizontal angles read off; it is then turned to another object, and the readings-off from the graduated circle again performed; and by the difference of the readings, the angular horizontal deviation is given; and when vertical angles are required, the readings are taken from the vertical circle in a similar manner.

THEODORE, of Mopsuestia, a well-known writer of the Syrian Church, and especially notable in connection with the controversy of 'The Three Chapters,' was born of a wealthy and distinguished family at Antioch, in the first half of the 4th century. He was the school-fellow and friend of St John Chrysostom, and his fellow-pupil under the philosopher and rhetorician Libanius; and he was induced, by the earnest exhortation of Chrysostom, to join with him in embracing the monastic life. His theological and scriptural studies were made under Flavian of Antioch and Diodorus of Tarsus; and having received priest's orders, he resided for a time at Antioch, where his learning and eloquence won the highest applause; and afterwards at Tarsus, under his old teacher Diodorus. About the year 390, or a little later, he was chosen Bishop of Mopsuestia in Cilicia. In 394, he preached in the presence of the Emperor Theodosius at Constantinople, on occasion of a synod held in that city. Of his further history, little is known; but his literary activity must have been prodigious, if we can judge by the contemporary accounts, and by the number of the works which are ascribed to him, but of which only fragments now remain. The most important of these consisted of commentaries on almost all the books of Scripture, and various polemical writings. A supposed tendency to Pelagian and Nestorian errors was observable in T., and was in part the occasion of the long controversy of the Three Chapters. This controversy, however, did not arise till long after the death of T., which took place about 427, after he had occupied the see of Mopsuestia for 36 or 37 years. Considerable fragments of T.'s commentaries have been published by Cardinal Mai in his *Spicilegium Romanum*, and some of his works still exist in Syriac.

THEODORE, Abyssinia. See SUPP. in Vol. X.

THEODORE'TUS (Gr. *Theodoretos*, God-bestowed), a celebrated church historian and theological writer, was born at Antioch, about the year 393, and received his name from the circumstance of his being supposed to have been granted as the fruit of earnest prayer, to his parents, who had long been childless. He was educated from early childhood in a monastery, where, among his fellow-pupils, were Nestorius and John of Antioch, both afterwards celebrated in the controversy which takes its name from the former. He was admitted among the clergy of Antioch; and at a comparatively early age became Bishop of Cyrus, a city of Syria. His zeal and eloquence were the theme of universal praise, and his success in bringing unbelievers and heretics to the church was almost unprecedented. In the controversies on the subject of Nestorius and his doctrines, which followed the condemnation pronounced by the council of Ephesus in 431, T. for a time took a warm and active interest. The party of Nestorius was with difficulty brought to an accommodation with Cyril of Alexandria, in virtue of which the condemnation of Nestorius by the council was acquiesced in by John, Bishop of Antioch. For a time, T. dissented from this condemnation of Nestorius; and he not only expressed these sentiments in a letter addressed to Nestorius himself, but also wrote formally against the celebrated anathemas of Cyril directed against Nestorianism. But he afterwards saw the necessity of yielding, and concurred in the deposition of those bishops who still persisted in their rejection of the council of Ephesus. Nevertheless, he by no means fully accepted the views of Cyril; and when, on Cyril's death, the opposition to Nestorianism began to develop, under the turbulent partisanship of his successor in the see of Alexandria, Dioscorus, into the contrary error of Eutychianism, T. endeavoured to induce Dioscorus to abandon his extreme opinions. Failing in the attempt, T. composed the work which has often figured in modern controversy, on account of the well-known passage as to the change of the Eucharistic elements which it contains, entitled 'Eranistes or the Many-shaped.' This work was regarded by Dioscorus as a renewal of the Nestorian error, and he accused T. to Domnus, the new Patriarch of Antioch, of that heresy. T. replied with great moderation; but Dioscorus persisted; and having engaged the imperial court on his side, succeeded in obtaining from the Emperor Theodosius II. an order confining T. within the limits of his own diocese. Meanwhile, the Eutychian controversy reached its height, and Eutyches (q. v.) having been first condemned by Flavian, Bishop of Constantinople, in a synod held in 448, was afterwards absolved in the celebrated Robber-council of Ephesus, under Dioscorus, in 449. The latter council not only excluded T. from its sittings, but formally deposed him from his see; whereupon he was compelled to retire to the monastery at Antioch in which he had received his first education. All this, however, was reversed by the general council of Chalcedon, in 451. T. did not very long survive his restoration. He died about the year 457. His works fill four volumes folio, reprinted in ten parts 8vo by Schulze (Halle, 1768—1774), and consist of commentaries on many books of the Old Testament and the

whole of St Paul's Epistles; a *History of the Church*, from 325 to 429 A.D., in five books; *Religious History*, being the lives of the so-called Fathers of the Desert, a series of most curious and interesting pictures of early ascetic life; the *Eranistes*, a dialogue against Eutychianism; *A Concise History of Heresies*, together with orations and a large number of letters. Of these works, his *History of the Church* is by far the best known, as well as the most important and interesting. See Schulze's edition of *Theodoreti Cyrensis Opera*.

THEODORIC, surnamed THE GREAT, the founder of the Ostrogothic monarchy, which comprised Italy, Sicily, South-eastern Gaul, Rhætia, Noricum, Pannonia, and Dalmatia, was born on the banks of the Neusiedler See, to the south of Vienna, in 455 A.D. His father, Theodemir, was one of the three brothers (the other two were Walamir and Widimir) who, on the death of Attila (453 A.D.), freed their nation from the yoke of the Huns, and being the representatives of the royal line of the Amali, exercised a united sovereignty over it; but the death of Walamir, and the departure to Italy and Gaul of Widimir with a part of the nation, left T.'s father sole ruler of the Ostrogoths who remained in Pannonia. Previous to these events, T. had been given as a hostage to the Eastern emperor, in accordance with whose directions he had been accustomed to all kinds of athletic and martial exercises, so that after his return (473) home, he was well qualified to fill the post of ruler of his ferocious and valiant kinsmen, which, by the death of his father, was left vacant in 475. In the previous year, the Ostrogoths had obtained parts of Mœsia and Dacia as settlements from the Emperor Zeno, and for years they gallantly defended the empire from foreign aggressors, other Gothic tribes included; but the impolitic faithlessness of Zeno produced in revenge the devastation of Thessaly and Macedonia, and subsequently (487) a raid directed on the capital itself. The emperor, to free himself from his troublesome ally, gave him permission to invade Italy, a suggestion gladly adopted by the warlike monarch, who started for Italy in 488; and after forcing his way through the Gepidæ and others who attempted to bar his progress, and gathering recruits on the way, arrived in the summer of 489 on the frontiers of Italy. Odoacer was both forewarned and forearmed; and a desperate conflict between the two powerful armies took place near Aquileia (28th August 489), distinctly to the advantage of the Ostrogoths. A second and more disastrous defeat was inflicted on Odoacer near Verona (27th September), after which he took refuge in Ravenna; but having again gathered a large force, he was totally routed a third time on the banks of the Adda (August 490), again blockaded in Ravenna, while the whole of Italy was being subdued; and having at last surrendered, was treacherously murdered (March 493). T. now assumed the title of *King of Italy*, resisted the claim of suzerainty preferred by the Eastern emperor; and with the exception of a victorious campaign against the Franks, to compel them to cease their assaults on the Visigothic dominions, the suppression of a rebellion in Spain against the authority of the infant monarch, his own grandson Amalric (during whose minority T. administered also the government of the Visigothic kingdom), and an expedition against the robber-hordes of the Bulgarians, the whole of his long reign was devoted to the consolidation and development of his new kingdom. His followers only received one-third of the conquered country; the rest was legally secured to the then possessors, and by degrees his barbarous followers were placed upon a footing of harmony with their fellow-subjects. T. made Ravenna his capital; occasionally, when his northern frontier was threatened, removing to Verona. He died in 526. T. holds the very highest rank among monarchs. An uneducated barbarian, and master of a power which even the most formidable of his neighbours, the Franks, could not have long withstood, he shewed no desire of conquest; cultivated the friendship and esteem of the surrounding nations; ruled all classes of his subjects with irresistible authority, but with corresponding justice and moderation; zealously promoted agriculture and commerce till Italy again took its old position as the most prosperous country in Europe; and, himself an Arian, exhibited a tolerance of all other sects, which the latter, when their turn for supremacy came, were very far from imitating. The foul blot on his character is the judicial murder of Boëthius (q. v.) and Symmachus, for a supposed connivance with the senator Albinus to restore the authority of the Eastern emperor in Italy; but every fact that can be gathered respecting this event bears out the belief that it was the result of a burst of passion, intensified by his extreme, nay, almost morbid, jealousy of Byzantine interference in Italy. The one great error of his administration consisted in his wholly neglecting to assimilate his Ostrogothic subjects with the previous inhabitants, either by a common code of laws, or by common official preferment; for though, under his sway, the evil of this separation did not appear, yet, when the sceptre fell to weaker hands, an antagonism necessarily arose between the ruling and the subject races, which was the chief cause of the successful restoration of Byzantine authority in Italy by Belisarius (q. v.) and Narses (q. v.). T. left no son; but his third daughter, Amalaswintha, succeeded him as regent for her son Athalaric; the eldest, Theodichusa, having become queen of the Visigoths, and the mother of Amalric; and the second, Ostrogotha, the wife of Sigismund, the last king of the Burgundians.

THEODOSIUS, the name of three later Roman emperors.—THEODOSIUS I., surnamed THE GREAT, and THE ELDER, to distinguish him from his grandson, was of Spanish descent, and was born either at Italica (as Gibbon and those who wish to make him of kin with Trajan maintain), or more probably at Cauca, near Segovia, about 346 A. D. His father, also named Theodosius, was the great general of the Roman Empire, who, after freeing South Britain from the savage Caledonians, who roamed over it at their pleasure, and annihilating the formidable rebellion of the Moor Firmus, which threatened to divorce the African provinces from the empire, was conspired against by his many malicious enemies at court, and summarily beheaded at Carthage in 376. T., who had accompanied his father in his British campaigns, and afterwards, by routing the Sarmatians, saved Mœsia from devastation, retired from active service after his father's murder, and occupied himself with the care of his patrimonial lands in Spain. But his many virtues and talents were not forgotten at court; and on the defeat and death of Valens (q. v.), his colleague, Gratianus (q. v.), feeling his inability to sustain alone the cares of empire, summoned T. from his retirement, invested him with the imperial purple, and confided to him, 19th January 379, the administration of Thrace, Dacia, Macedonia, Egypt, and the East, and especially the protection of the empire against the Goths. This last charge called for the full exercise of the new emperor's abilities, for the army at his command dared not face the Goths in the open field; and even when, after the death of their able leader, Fritigern, the Ostrogoths and Visigoths separated, each breaking up into several bands, T. found it most prudent

to sow jealousy and dissension among them by promises and bribes, and after a four years' so-called campaign, succeeded in pacifying the Visigoths, the Ostrogoths retreating towards Scythia. The latter returned in 386, their ranks swelled by Scythians, but were totally routed in attempting to pass the Danube, and the survivors were transported to Phrygia and Lydia. In 387, T. undertook to restore to the throne of the Western Empire Valentinian II. (whose sister, Galla, he married), the brother of Gratian, who had been expelled by Maximus; and after a uniformly successful contest, the usurper was captured and put to death at Aquileia. In 392, the suspicious death of Valentinian, and the elevation of the puppet Eugenius by Arbogastes, the real ruler of the West, again summoned T. to interfere; and after two years of preparation, his motley army of Byzantines, Goths, Alans, and Huns, aided by the treachery of some of Eugenius's generals, gained a complete victory over the Gauls and Germans, who chiefly constituted the army of the West; and the two portions of the Roman Empire were again united under one ruler. The union, however, lasted only four months, owing to the death of T., 17th January 395. T., though a professor of the orthodox Christian faith, was not baptised till 380, and his behaviour after that period stamps him as one of the most cruel and vindictive persecutors who ever wore the purple. His arbitrary establishment of the Nicene faith over the whole empire, the deprivation of civil rights of all apostates from Christianity and of the Eunomians, the sentence of death on the Manicheans and Quarto-decimans (q. v.), all prove this; though the want of evidence for the direct execution of these severe laws, somewhat modifies the unfavourable impression they produce, and inclines us to believe, that, like the massacre at Thessalonica, they were the result of a sudden access of savage passion, carefully fanned by his interested ecclesiastical advisers. His humiliation before St Ambrose, Bishop of Milan, for the massacre at Thessalonica, was regarded by the church as one of its greatest victories over the temporal power. See AMBROSE.—THEODOSIUS II., surnamed THE YOUNGER, the only son and successor of Arcadius (q. v.), was born 401 A.D., succeeded his father when eight years old, and occupied the throne of the East for 42 years. The chief events of his reign were the invasion of the empire by the Huns under Attila, a war with Persia, renewed efforts to extirpate paganism, and the compilation of the *Codex Theodosianus* (see CODE). The emperor himself was the feeblest of rulers, and was much better adapted for the cowl than for the sceptre and sword.

THEO'GONY, the name given in ancient Greece to a class of poems recounting the genealogy of the gods. Musæus (q. v.) is said to have written the earliest Theogony; but his work, as well as the Theogonies of Orpheus (q. v.) and others, have perished; that of Hesiod (q. v.) being the only one that has come down to us.

THEO'LOGY (Gr. *theologia*, lit., a speaking or writing about God) is a term employed to denote the theory of the Divine nature and operation. It first occurs in Plato and Aristotle, who understand by it the doctrine of the Greek gods, and of their relation to the world. Homer, Hesiod, Orpheus, &c., are called *theologoi* (theologians), on account of the subject-matter of their verse. But their theology is at the same time called 'mythic,' to distinguish it from the 'physical' theology of the philosophers, which, reversing the mythic order, concerned itself with speculative inquiries regarding the origin of the world and its relation to the gods. In the New Testament, the word theology does not occur, and the idea seems alien to the simplicity of the primitive Christian faith. The Greek Christians originally designated any deep philosophical apprehension of the truths of religion by the term *Gnosis* (knowledge), which was opposed to *Pistis* (faith), the simple irreflective trust of the majority of humble believers. First during the 3d and 4th centuries the word theology came into use, especially in connection with such of the Fathers as defended the doctrine of the Deity of the Logos. In this sense, the Evangelist John and Gregory of Nazianzen were termed *Theologians*. During the same period, the word theology was applied to the doctrine of the Trinity. In the century following, its application was widened by Theodoret, who used it to denote the whole circle of theoretical instruction in religion; and finally, Abelard, through his *Theologia Christiana*, gave the word that comprehensive signification it still bears, as expressive not only of a theoretical but also a practical exposition of religious truth. The word Divinity is sometimes used to denote the same thing as theology.

THEO'PHILUS, one of the most important precursors of Dr Faust, was, according to the legend, coadjutor-bishop at Adana, in Cilicia. After the death of his bishop, being unanimously chosen successor, he declined the proffered honour, but was shortly afterwards, at the instigation of slanderers, deposed from his former office by the new bishop. He now had recourse to a Jew magician, who took him to a midnight meeting of devils, whose chief ordered him to deny Christ and Mary, and to give a bond, making over his soul. The result was, that next morning he was reinstated in his office and dignities by the bishop; and now, presuming on the support of his confederates, he began to assume a supercilious and domineering manner. But he was soon overtaken with remorse, and, through forty days' fasting and prayers, prevailed on Mary to intercede with her son for him, and to get back the letter from the devil, which she laid upon the breast of the repentant sinner, as he lay asleep in the church. T. then made a public confession of his crime, told of the goodness of the Virgin Mary, and died three days after. This legend, whose origin is traced back to an unknown Greek, of the name of Eutychianus, was brought, during the 10th c., through an equally unknown Neapolitan priest, named Paulus, to the West, where it very quickly spread far and wide. Before the end of the century, it was put into Latin verse by Roswitha, and still better, by the Bishop of Rennes, who died in 1123 (printed in the *Acta Sanctorum*, February 4; and in *Hildeberti Turonensis et Marbodi Opera*, published by Beaugendre, Par. 1708). Gauthier de Coinsy (died after 1236) turned it into a beautiful French poem (printed in *Œuvres de Rutebeuf*, published by Jubinal, 2 vols.); and the Rhenish compiler of the *Alte Passional* admitted it among his legends of Mary (*Marienlegenden*, published by Pfeiffer, Stuttg. 1846). A Dutch metrical version, in the 14th c., was published by Blommaert (*Theophilus*, Ghent, 1836). The first dramatic handling of the subject was in French by Rutebeuf, a distinguished troubadour of the 13th c. (*Œuvres*, published by Jubinal, 2 vols., Par. 1839); then repeatedly during the 14th and 15th centuries in Low-German (*Romantische und andere Gedichte in altplattdeutscher Sprache*, published by Bruns, Berl. and Stettin, 1798; *Theophilus, in Icelandic, Low-German, and other Tongues*, by Dasent, Lond. 1845). The legend of T. is also not seldom to be found inserted in large works, and frequent allusions to it occur in Latin, German, Anglo-Saxon, Icelandic, Swedish, French, and even Spanish literature. It has even

been pictorially represented in French churches. With the 16th c., it seems to have disappeared. However much the various versions differ from one another in the minor circumstances, the essential traits remain throughout unchanged; that T. made a compact with the devil in order to recover lost property; that he attained his object, but at the same time nothing more (nothing whatever of magic art), and that Mary rescued the repentant sinner. Through this legend of T., the oldest known instance of a compact with the devil, there runs a lenient spirit (derived from paganism, and which the Roman Catholic Church was able to sanction by interposing the Virgin Mary), which distinguishes it markedly and essentially from the stern Protestant shape of the devil's compact in the Faust-book, which, with rigorous consistency, requires the consignment of the contracting party to hell.

THEOPHRA'STUS, the Greek moralist and naturalist, was born at Eresus, in Lesbos, and studied philosophy at Athens, first under Plato, and subsequently under Aristotle. The latter took especial interest in him, and according to a rather incredible legend, altered his original name of Tyrtamus into that of Theophrastus (divine speaker), in compliment to the fluent and graceful speech of his pupil. To T., moreover, he bequeathed the presidency of the Lyceum, his library, and the original MSS. of his writings. T. proved a worthy successor of the Stagirite. Under his presidency, the Lyceum sustained its character, and attracted no fewer than 2000 disciples, among whom was the comic poet Menander. The kings Philippus, Cassander, and Ptolemy held him in high esteem; and such was the admiration of the people of Athens for him, that, when he was arraigned for impiety and triumphantly acquitted, they would have killed his accuser, had he not generously interceded. In compliance, however, with the law of Sophocles, which decreed the banishment of all philosophers from Athens, T., in 305 B.C., left the city, until the enactment was repealed the very next year by Philo, also a disciple of Aristotle. From that date, T. continued his lectures until his death in 287, at which time he had presided over the Academy for 35 years. His birth being unknown, we are ignorant of his age at the time of his death, and conjectures variously give it from 85 to 107 years. On the eve of dissolution, he is said to have complained of the shortness of human life, which ended just when he was about to solve its enigmas. He was accompanied to the grave by the entire Athenian population. He bequeathed his library to Neleus of Scepsis. The great object of his philosophical labours was to develop the Aristotelian system, to explain the difficulties which obscured it, and to fill up the gaps which left it incomplete. Most of the works which he wrote with this object have perished; only the following remain: 1. *Characteres*, in 30 chapters, descriptive of vicious characters; 2. *Of Sensuous Perception and its Objects*; 3. A fragment on *Metaphysics*; 4. *Of the History of Plants*, in 10 books, one of the earliest of extant treatises on botany; 5. *Of the Causes of Plants*, in 8 books, of which, however, only 6 remain; 6. *Of Stones*. The best complete edition of T. is that of Schneider; the best edition of the *Characteres* separately is that of Ast.

THE'ORY, a word expressing the scientific process of generalisation under various aspects.

Theory is, in the first place, opposed to Fact, or matter of fact, and signifies that a certain class of facts have been generalised and brought into a single comprehensive statement. It thus corresponds to a Principle, general truth, or Law of Nature. That a half-inflated bladder hung before the fire is expanded till it bursts, is a matter of fact; that bodies generally are expanded by heat, is the theory or general principle, comprehending the whole class of facts. To give the theory of a fact, in this sense of the word, is to give its general law; this is also called its Explanation, and sometimes its Cause. See CAUSE.

Theory, in the next place, is opposed to Hypothesis (q. v.). A fact may, for a time, be referred to a hypothetical or assumed principle; endeavours being meanwhile made to remove the hypothetical character, by proving or disproving the principle. The vortices of Descartes was a hypothesis to account for planetary motions; while Newton's view, that gravity might be the cause of these motions, was, in the first instance, a hypothesis. The Cartesian doctrine was disproved and abandoned; the Newtonian was fully verified, and, ceasing to be a hypothesis, became a theory.

Lastly, Theory is opposed to Practice. The Theory of a subject is the knowledge or explanation of it; the Practice is making some use of it. Physiology is Theory; Physic, or Medicine, is practice. In practical matters, there are two modes of procedure which are still further illustrative of the distinction now in hand. The knowledge possessed by a worker in any art may be empirical, experimental, rule-of-thumb—that is, it may be gathered by actual experience in the particular operation. The seaman's knowledge of the prognostics of weather, and the cook's art in boiling and roasting, are usually of this kind. On the other hand, the worker's knowledge may be obtained from Theory, in other words, from general principles or laws scientifically ascertained; as when the theory of the winds and the law of storms are employed to predict the weather; when the cook roasts and boils according to the known temperature for coagulating albumen; and when a physician prescribes a dietary grounded on a chemical analysis of the food and of the tissues to be maintained. Great caution is required in the employment of such theoretical knowledge in the arts and in practical affairs. It is not enough that the theories are fully established; we must also know all the conditions of the case, so as to allow for every agent operating to produce or to mar the effect. That a cannon-ball should describe a parabola, is a correct theoretical inference from gravity and the laws of motion; but the resistance of the air, a distinct agency, makes it untrue in fact, and therefore misguiding in practice. When this resistance is allowed for, the theory is complete, and its application will no longer disappoint the operator. See DEDUCTION.

THEO'SOPHY (Gr. *theosophia*, divine wisdom), the name given to a so-called sacred science, which holds a place distinct as well from that of philosophy as from that of theology, even in questions where these latter sciences have the same object with it, namely, the nature and attributes of God. In investigating the divine nature and attributes, philosophy proceeds entirely by the dialectic method, employing as the basis of its investigation the ideas derived from natural reason; theology, still employing the same method, superadds to the principles of natural reason those derived from authority and revelation. Theosophy, on the contrary, professes to exclude all dialectical process, and to derive its knowledge of God from direct and immediate intuition and contemplation, or from the immediate communications of God himself. Theosophy, therefore, so far as regards the science of God, is but another name for MYSTICISM (q. v.), although the latter name implies much more and the direct and immediate knowledge or intuition of God, to which the Mystics laid claim, was, in fact,

the foundation of that intimate union with God, and consequent abstraction from outer things, which they made the basis of their moral and ascetical system. The theosophic system dates from a very high antiquity; and within the Christian period we may number among Theosophs, the Neo-Platonists, especially Plotinus, Iamblichus, and Proclus; the Hesychasts of the Greek Church; all those of the medieval Mystics who laid claim to any dogmatical theory; and in later times, the Paracelsists, Bodenstein and Thalhauser, Weizel, Jacob Böhme, and above all, Emmanuel Swedenborg. If we consider one particular view of the philosophic system of Schelling, he also may be assigned to the same school.

THERAPEU'TÆ, a pious 'Jewish' sect, mentioned in a book ascribed to Philo, as living chiefly on the Lake Mareotis, near Alexandria, but as having also numerous colonies in other parts of the world. They are described as in many respects like the Essenes (q. v.). Like them, they lived unmarried in a kind of monastery, were very moderate with regard to food and dress, the latter consisting in a white garment; prayed at sunrise, their face turned to the sun; studied much in the Scriptures—which they explained allegorically—and in other 'ancient books,' and were principally opposed to slavery. The chief differences between these two 'sects,' as they are described to us, consisted in the T. simply living a life of contemplation, while the Essenes followed many occupations, such as agriculture, arts, &c.; the latter lived together, while the T. lived separately in their cells; the Essenes not only took an interest in other human beings, but actively assisted them; while the T., who also, before they entered the brotherhood, divided their property among their relatives, contrary to the 'common treasure' of the Essenes, kept in utter ignorance of the outer world. Again, the T. knew none of the divisions which marked the degrees of initiation among the Essenes, but they held the Temple at Jerusalem in much higher veneration than the latter; the T. brought up boys to the brotherhood, while the Essenes only recruited themselves from grown-up people. One of the chief characteristics of the T. was also the religious meals they used to hold in common on every seventh Sabbath; the Essenes having two such sacred meals daily. Many and striking are also the analogies offered by their mode of life and their doctrines to those of the Pythagoreans. Neither partook, e. g., of animal food or wine, and both admitted women to their assemblies, which were mostly concluded with hymns; and they both held the number seven sacred. Many theories have been broached regarding this mysterious sect. One of the most plausible notions is the one—latterly much discussed—of the whole book *De Vita Contemplativa*, which treats of this sect, being falsely attributed to Philo. It is rather believed to be the work of an early Christian, intended to idealise the life of Christian monasticism and asceticism of the first centuries. See ESSENES.

THERAPEU'TICS (Gr. *therapeuo*, I heal) is that division of the science of medicine which treats of the various actions of remedies upon the diseased animal system, or the means by which nature may be aided in her return to health.

THERAPI'A, or TARAPIA, a village of European Turkey, province of Rumili, is situated on the Bosporus, 21 miles north-north-east of Constantinople, at the head of a large and beautiful bay of the same name. It is one of the most charmingly picturesque spots in the neighbourhood of the Turkish capital, and all summer has a climate deliciously cool. T. is the residence of the French and English embassies, and many of the Frankish merchants have villas here.

THERAPO'NIDÆ, a family of acanthopterous fishes, allied to *Percidæ*, from which they are distinguished by having 6 instead of 7 branchiostegal rays. The scales in some are ctenoid, in others cycloid. Some are fresh-water fishes. None are British. Some are found in the lakes and rivers of North America.

THERESIO'PEL, more commonly called MARIA-THERESIOPEL (Ger. *Theresienstadt*), an important town of the Servian Wojwodschaft, 24 miles west-south-west of Szegedin, on the Palitsch Lake. It is well built, but unpaved; contains numerous important buildings, as the churches, gymnasium, and the great barracks. Manufactures of leather and shoes, linen-weaving, dyeing, the cultivation of tobacco and fruits, together with the rearing of cattle, are the chief branches of industry. Pop. 53,499.

THERI'ACA (Gr. *ther*, a wild or a venomous animal), a medicine in the form of an electuary, supposed to be an antidote to the poison of venomous animals. It was invented by Andromachus of Crete, physician to the Emperor Nero, and was described in a poem, preserved in Galen's work, *De Antidotis*. This theriac was a mishmash of about 70 ingredients, some of them quite inert, and others antagonistic to one another. Yet it continued in repute until recent times, and it is not long since in Venice, Holland, France, and other places, the druggists had to prepare the compound with certain solemnities in the presence of the magistrates. The term theriaca was applied to various compounds of a similar nature, and *theriac* and *theriacal* became synonymous with medicinal. The English word *treacle* is a corruption of *theriacal*, and originally meant an electuary, or compound syrupy medicine (e. g., Venice treacle = the theriac of Andromachus); and it was applied to molasses from the similarity in appearance.

THE'RMIDOR, i. e., the 'Hot Month,' formed, in the calendar of the first French Republic, the 11th month, and lasted from the 19th July to the 18th August. The 9th Thermidor of the Republican year 2 (July 27, 1794) is historically memorable as the date of Robespierre's fall, and the termination of the Reign of Terror. The name Thermidorians was given to all those who took part in this fortunate *coup d'état*, but more particularly to those who were desirous of restoring the monarchy.

THERMO-DYNAMICS, or the DYNAMICAL THEORY OF HEAT. See SUPP. in Vol. X.

THERMO-ELECTRI'CITY treats of the currents that arise from heating the junction of two heterogeneous conductors. Such currents can be obtained in many ways, but we shall here simply indicate the more important.

Thermal Currents with one Metal.—Take a copper wire, cut it in two, and fix each half in one of the binding screws of a galvanometer. Heat one of the free ends to redness, and press it against the other, and a current will be generated, passing at the junction from the hot to the cold end, as shewn by the deflecting needle. In almost all cases where portions of the same metal at different temperatures are pressed together a current is produced, the direction of which depends on the metal, and even on the structure of the same metal.

Currents are also obtained when two portions of the same metal or piece of metal have different structures, and the point where the two structures meet is heated. If, for instance, one piece of wire be hard-drawn and the other part annealed, when

the seat of change from the one to the other is neated, a current is produced. Or if the whole be annealed, and one part of it be hammered, the hammering makes the other part harder, and the current, when the junction is heated, passes from the soft to the hard part. The direction of the current differs with different metals in these circumstances. Even the difference of structure introduced by the twisting of a portion of a wire, causes a current to flow when the wire is heated in the vicinity of the twist. Thus, when a knot is tied on a platinum wire, or when part of it is coiled into a spiral, a current passes always towards the knot or coil when the flame of a spirit-lamp is directed on a portion of the wire near the knot or spiral. The twisting, in this case, acts as hardening or hammering would do. By running the flame of a spirit-lamp along a metal, it frequently happens, more especially if it be of a crystalline structure, that currents are produced at certain points. These points are supposed to indicate a change in structure. If a bar of fused antimony have its ends connected with a galvanometer, and examined in this way, *neutral points* are generally found. The flame of a lamp generates a current near these points, always passing towards the point, and changing in direction with the change of the side on which the flame is applied. Bismuth shews neutral points, but the current always goes from the cold to the hot part across the neutral point. In bars of those metals which are crystallised regularly and slowly, no neutral points are found.

Thermal Currents with two Metals.—A current is always obtained when the point of junction of any two metals is heated. The two metals which shew this property in the greatest degree are bismuth and antimony. When a bar of antimony, A (fig. 1), is soldered to a bar of bismuth, B, and their free extremities are connected with a galvanometer, G, on the junction being heated, a current passes from the bismuth to the antimony, as shewn in the figure. When S is chilled by applying ice, or otherwise, a current is also produced, but in the opposite direction. Such a combination constitutes a thermo-electric pair. Applying the same mode of explanation to this pair that we apply to the galvanic pair (see GALVANISM), bismuth is positive within and negative without the pair, antimony negative within and positive without the pair. Bismuth thus forms the negative pole, but positive element; antimony the positive pole, but negative element of the pair. The metals may be classed in thermo-electric just as in electro-chemical order. The following table gives them in this order, the direction of the arrow shewing how the current goes within the pair:

he order and numbers in this table, which are for emperatures between 40° and 100° F., are those given by Dr Mathiessen. For other temperatures the table would be different for several of the metals.

It will be seen, that metals like bismuth and antimony, which have a crystalline structure, are best suited for a thermo-electric pair. Tourmaline, when heated, shews an opposite electricity at each end. If it had a low conducting power like the metals just named, we might expect from it a thermo-electric current instead of mere polarity. It is probable that the crystalline structure, however, accounts for the appearance of electricity in both cases.

Thermo-electric Pile or Battery.—One bismuth-antimony pair is of very little power. To increase this, several pairs are associated together, as shewn in fig. 2, where the same tension-arrangement is adopted as in a galvanic battery. The heat in this case must be applied only to one row of soldered faces. The current depends on the difference of temperature of the two sides. When a strong current is required, the one series must be kept in ice, or in a freezing mixture, whilst the other is exposed to heat radiating from a red-hot plate of iron. As in the galvanic pair, the electro-motive force is proportionate to the number of pairs; the size of the bars, like the size of the galvanic plates, merely aiding to diminish the resistance. The electro-motive force of a thermo-electric battery is small; according to Dr Mathiessen, that of 25 bismuth-tellurium pairs equals one cell of Daniell's battery, when the one series is kept at 32° F. and the other at 212° F. In consequence of the low electro-motive force of the thermo-electric battery, the galvanometer to be used with it must introduce as little resistance as is consistent with the best effect on the needle. Hence special galvanometers are used, in which the coil wire is short (200 turns) and thick ($\frac{1}{15}$ inch); these are called thermo-galvanometers.

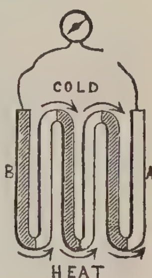

Fig. 2.

When a great number of pairs are formed into a battery, they may be conveniently arranged as in fig. 3, which shews one of 30 pairs. The odd faces, 1, 3, 5, &c., are exposed on the one side, and the even faces, 2, 4, 6, &c., on the other. The terminal bars are connected with the binding screws *n*, *p*. The interstices of the bars are filled with insulating matter (gypsum) to keep them separate, and the frame in which the whole is placed is of non-conducting matter. Such a pile in conjunction with a thermo-galvanometer (see GALVANISM) forms the most delicate thermometer for radiant heat, and is generally called a *thermo-multiplier.* When placed in a room, the temperature of which is equable all round, no current is produced; but if heat be radiated more on one side than another, a current ensues. If the hand, for instance, be brought near on the one side, a current indicates its radiant power; or if a piece of ice be brought near, a current is also shewn, but moving in the opposite way.

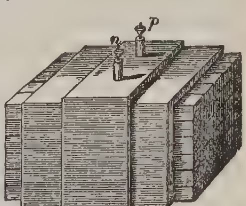

Fig. 3.

Thermal Effects produced by the Galvanic Current.—As heat or cold produces a current at the

junction of two dissimilar conductors, we should expect that if a galvanic current be made to pass through the junction, heat or cold would follow, and such is found to be the fact. When a current from a voltaic cell passes, as shewn in fig. 4, through a system of three rods of bismuth, antimony, and bismuth, at the junction where the current passes from bismuth to antimony, cold is produced; and at the other, from antimony to bismuth, heat. If, for instance, water be placed in a hollow at either junction, cooled to 32° F., it will become frozen when the current passes from the bismuth to the antimony. When the junction of these two metals is put into the bulb of an air thermometer, so that a current can be sent through it in either way, the air expands when the current goes from antimony to bismuth, but contracts when it goes in the opposite way. Powerful currents must not be used, otherwise heat will be produced at all the junctions. Seebeck was the discoverer (1821) of thermo-electricity; Nobili invented the thermo-electric pile (1834); Peltier (1834) first observed the thermal effects of galvanic currents at the junction of heterogeneous conductors. See also T.-E. and T.-MAGNETISM in SUPPLEMENT in Vol. X.

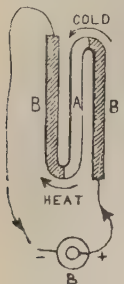

Fig. 4.

THERMO'METER (Gr. literally *heat-measurer*), a term which, in spite of its derivation, is usually restricted to instruments which measure temperature (see HEAT) by the *expansion* of bodies. Like that of the telescope and microscope, and many other valuable pieces of philosophical apparatus, its early history is very obscure. There are various claimants who seek to share at least a part in the credit of its invention; and they agree pretty well in referring it to somewhere in the beginning of the 17th century. We shall not waste space in endeavouring to settle such matters of history, but proceed at once to a description of the forms of the instrument now most commonly used; after which we shall say a few words about the actual value of their indications, and finish by a rapid sketch of a few other instruments also adapted for the measurement of temperature, but not usually known by the name of thermometer.

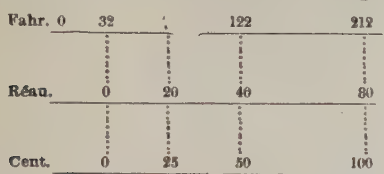
Let us commence with the ordinary spirit-thermometer, as it is called; where the indications are given by the expansion of a quantity of alcohol which fills entirely a glass bulb, and partially a narrow tube attached to it.

To construct such an instrument, a capillary tube is selected, of as uniform a bore as possible. The easiest method of testing its uniformity is to introduce a column of mercury, about an inch long, into the tube, and gradually move it along by inclining the tube, carefully measuring the length of the column in each of its successive positions. It is obvious that the column will be longer the smaller is the mean section of the portion of the tube occupied at any time by the drop of mercury. If considerable differences of length are found, the tube is rejected at once. The best tubes are those which, if shewing any change, taper very slowly but nearly uniformly from one extremity to the other; a defect which can easily be allowed for in the subsequent graduation of the instrument. A bulb is blown on one end of the selected tube; large, if the instrument is meant to be very delicate; small, if a common instrument is to be made, or one which will work through a great range of temperature. The bulb is heated to expand the contained air, and then the open end of the tube is plunged into alcohol, usually tinged with colouring matter, for greater visibility. As the bulb cools, the atmospheric pressure on the alcohol in the vessel forces some of it into the stem, and perhaps a little into the bulb. The tube being then inverted, a few dexterous taps suffice to shake the greater part of the alcohol into the bulb. The lamp is again applied, with caution, until the alcohol boils, and the rapidly escaping vapour drives the air almost entirely from the tube, whose open end is immediately plunged again into the coloured spirit. Unless the stem be nearly 40 feet in length—and thermometers have been made by Forbes (q. v.) of a length approaching to this for the measurement of underground temperature—the alcohol fills the whole of the ball and stem as soon as the glass has cooled. The bulb is again cautiously heated so that, by the expansion of the spirit, such a portion may be expelled, that when the whole has again cooled, the level of the liquid in the tube may stand near some point previously determined on with reference to the particular employment for which the instrument is destined. Finally, the lamp being again applied to the tube, near the upper surface of the liquid, that portion of the spirit is again made to boil; and while the vapour keeps the free end of the tube clear of air, that end is hermetically sealed; and the glass-blower's part of the work is done. A somewhat similar, but more difficult process has to be gone through if other liquids, such as ether, sulphuric acid, mercury, &c., are employed to fill the bulb; each of these liquids having its own special use in certain philosophical inquiries, as we shall presently see. It only remains that the instrument be *graduated*, so that some definite information may be given by its indications.

In the older thermometers, the scale was arbitrary, so that no comparable readings could be taken by means of different instruments. In the finest modern instruments, also, the scale is usually quite arbitrary, being, in fact, engraved on the tube during the process of calibration above described. But then, by careful observation, certain definite temperatures are measured in terms of this arbitrary scale, so that the value of a degree and the position of some definite zero-point are determined for it, and the result engraved on the tube. These numbers enable us, by an easy calculation, to reduce the observed reading of the fine instrument to its equivalent in some of the standard scales.

At present, we assume, what is very nearly true for mercury at least, that equal increments of bulk correspond to equal increments of temperature. All, then, that is necessary is to fix two definite temperatures, and assign their positions on our scale. Water being one of the most common bodies in nature, and being everywhere easily obtainable in a state of great purity, is usually employed; and its *freezing* and *boiling* points are taken as the definite points. The temperature of freezing water or of melting ice is almost absolutely fixed, for (see HEAT) pressure alters it only very slightly. It is otherwise with the boiling-point of pure water, for this is considerably raised by increase of pressure; so much so, in fact, that if the barometer be not attended to, an error of several degrees is possible. Hence we must define the particular pressure, usually 30 inches, at which the boiling-point is to be determined. The thermometer, constructed (so far) as above described is to have its bulb, and nearly the whole of the portion of the stem which contains liquid, immersed in pounded ice, from which the melted portion is freely trickling; and when the level of the spirit has become stationary, its position, the *freezing-point*, is marked on the tube. Similarly, the barometer standing at 30 inches, the bulb is enclosed in the

steam immediately above the surface of water freely boiling. We thus obtain the *boiling-point.* It only remains that we decide by what numbers these points shall be indicated, because (on account of the nearly uniform expansion of mercury) then the remaining divisions can be at once filled in by dividing the interval between them into equal parts, or, if necessary, allowing for a slight taper in the tube. The only scales which require mention are those of Fahrenheit, Réaumur, and Celsius. Of these, the first is commonly used in Britain, the second in Germany, and the third in France; but this last, under the name of the *Centigrade* scale, is almost exclusively used by scientific men of all nations. The relations of these scales will be easily understood by means of the following figure:



In the Fahrenheit scale, the freezing-point is 32°, and the boiling-point 212°, so that the space between these is divided into 212 − 32, or 180, equal parts or degrees. In the others, the freezing-point is the zero, but the boiling-point is 80° and 100° respectively. It is of course perfectly easy to reduce from one of these scales to another. Thus—What is the Centigrade reading for 77° F.? (see the dotted line in the figure). The numbers in Fahrenheit's scale are all too great by 32, because 32°, and not 0°, stands for the freezing-point. Subtract this from 77, and we have 45. Hence the required number of Centigrade degrees must bear the same ratio to the 100 from freezing to boiling in that scale that the 45 bears to the 180 degrees between the same limits in Fahrenheit's. The requisite number is therefore $\frac{45}{180}100 = 25°$ C. In words—*To convert Fahrenheit to Centigrade, subtract* 32, *and multiply by* $\frac{100}{180}$, *or* $\frac{5}{9}$. Vice versâ—*To pass from Centigrade to Fahrenheit, multiply by* $\frac{9}{5}$, *and add* 32. Thus the Fahrenheit value of 50 C. is $\frac{9}{5}50 + 32 = 122$, as in the figure. Of course the similar processes with Réaumur's scale present no difficulty.

It is supposed that Fahrenheit fixed his zero at the point of greatest cold that he had observed, possibly in Iceland, more probably by means of a freezing mixture, such as snow and salt, or sal-ammoniac. It is much to be desired that the Centigrade scale alone were employed.

A mercurial thermometer ceases to be of use for temperatures only a little above the freezing-point of mercury; but it has a wide range upwards, as mercury does not boil till about 600° C. On the other hand, a spirit-thermometer, though of little use beyond about 50° or 60° C., as alcohol boils at 70° C., is useful for any degree of cold yet produced, as alcohol has never yet been frozen. When extreme sensitiveness is required, ether being considerably more expansible than alcohol, is sometimes employed; as by Thomson in detecting the effect of pressure on the freezing-point of water. Water, again, would be about the very worst substance with which a thermometer could be filled; for not to speak of its expanding in the act of freezing, and therefore necessarily bursting the instrument, if it were ever allowed to reach the freezing-point, its scale would read partly backwards and partly forwards; for as ice-cold water is gradually heated up to 4° C. it contracts, and begins to expand again after that limit has been passed.

To make thermometers self-recording, various schemes have been proposed, of which we shall notice only one or two. Those most commonly used indicate only the *maximum* and the *minimum* temperature during each 24 hours, or during the interval which has elapsed since they were last set. The usual arrangement consists of two thermometers, a mercurial and a spirit one, fixed horizontally to the same frame, with their bulbs at opposite ends of the frame. Above the mercury is a small piece of steel or ivory, and *in* the spirit a small and light float of glass or enamel. As the mercury expands, it pushes the steel before it, and when it again contracts it leaves it behind; the end nearest the mercury thus remaining at the highest or maximum indication which that thermometer has given. In the spirit-thermometer, the liquid, as it expands, freely passes the enamel, and leaves it undisturbed; but it can never contract so as to leave it dry. It therefore pulls the enamel back when it contracts, and thus the extremity farthest from the bulb marks the lowest point which the spirit has reached, or the minimum temperature. To set this instrument, incline it so that the steel falls back to the surface of the mercury—the enamel at the same time comes to the surface of the spirit. The registering thermometers of Negretti and Zamba are the most esteemed. Walferdin's maximum is ingenious.

The best mode of registration is undoubtedly the photographic. For this purpose, a mercurial thermometer is placed vertically before a narrow slit, in such a way that no light can pass through the slit save above the level of the mercury in the tube. A gas flame is kept burning at some distance in front of the slit, the bulb of the thermometer being protected from its radiation; and behind the slit, a sheet of prepared photographic paper is exposed to the narrow line of light which passes above the mercury. This paper is fixed on a cylinder with a vertical axis, which is made to revolve uniformly by clockwork. Lines are drawn by the clockwork on the paper, giving the position of the slit at each hour of the 24, or the gas-flame is mechanically reduced or eclipsed at intervals of an hour; so that the record, when photographically developed, gives the temperature for every minute of the day and night, in a form represented below; where the blackened

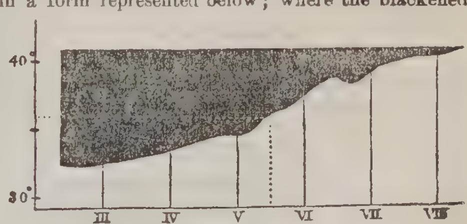


Fig. 1.

space represents the portion of the paper which has been exposed to the light. To find from such a record what was the temperature at any hour, say, 5 hours 30 minutes A.M., draw a vertical (dotted) line, as in the figure, half-way between the V and VI lines, and from the point where it meets the dark space, draw a horizontal (dotted) line. This intersects the scale (to the left in the figure) at 36°, the temperature required.

Among ordinary meteorological instruments, the *wet-bulb* thermometer is deserving of notice. It is simply an ordinary thermometer, with the bulb

covered with paper or cotton-wool, kept constantly moist by the capillary action of a few fibres connecting it with a small vessel of water. If the air be *saturated* with moisture (see DEW, EVAPORATION), there will be no evaporation, and the wet-bulb thermometer will give the same indication as the dry-bulb. But the drier and the warmer the air is, the faster does the water evaporate, and (the latent heat of vaporisation being mainly taken from the moist bulb) the lower does the mercury sink in the moist-bulb instrument. The difference between the readings of the two instruments, compared with the actual temperature, as shewn by the dry-bulb, thus leads to a determination of the hygrometric state of the air.

So far, we have spoken of the instruments now in common use. But the *air*-thermometer was probably the oldest form; and possesses a scientific superiority over those just described. Theoretical and experimental investigations, connected with the modern Dynamical Theory of Heat (see FORCE, HEAT), shew that equal increments of heat produce almost exactly equal changes of bulk in a nearly perfect gas, such as air, if the pressure to which it is exposed be constant. Hence, temperature, as measured by an air-thermometer, gives a true indication of the quantity of energy present in the form of heat. As the comparison of an air-thermometer with a mercurial one shews that, for temperatures not greater than 300° C., or 572° F., the indications of the two agree very closely, the ordinary mercurial thermometer practically possesses within these limits the same advantage.

As the pressure of a gas depends on the amount of heat it contains, the *absolute zero* of temperature, or the temperature of a body wholly deprived of heat, may be determined by finding the temperature at which a perfect gas would cease to exert pressure. For ordinary temperatures, it is found (see HEAT) that air increases in bulk by ·3665, and hydrogen by ·3668 of its bulk, when heated under constant pressure from 0° to 100° C. Again, by Boyle's law, if the air be compressed again, at constant temperature 100° C., to the bulk it had at 0° C., its pressure is increased by ·3665 of its former amount. Thus, p_0 being the pressure at temperature 0° C., p_t that at $t°$ C., we have, when the volume is kept constant,

$$p_t = p_0(1 + \cdot003665t).$$

If we assume this to hold for all temperatures, p_t vanishes when

$$1 + \cdot003665t = 0;$$
$$\text{or } t° = -274° \text{ C. very nearly.}$$

That is to say, at 274° C. under the freezing-point of water, a perfect gas ceases to exert pressure on its containing vessel—i. e., is deprived of that thermal energy on which pressure depends.

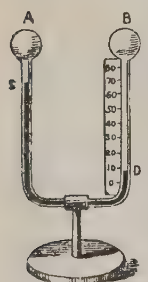

Fig. 2.

The air-thermometers in common use are affected by the pressure, as well as the temperature, of the atmosphere. To avoid this inconvenience, Leslie and Rumford in the present century revived the *Differential Thermometer* of Sturmius. This instrument, in one of its many forms, is represented in fig. 2. Here a bulb is blown at *each* end of the tube (which is bent into a U-form), and the liquid in the stem is used merely as an index, both balls being full of air. The length of the column of fluid is usually adjusted so that it can just fill one of the vertical arms and the horizontal portion of the tube; and the quantities of air in the two balls are so adjusted, that the column will take this position *when the two balls are at the same temperature.* If the ball A be heated more than B, the liquid index will take a new position, such as CD, and this is read off by a scale applied to either of the vertical arms. The graduation of this instrument may be effected by calculation, but it is usually done experimentally. Leslie made good use of it in his investigations on heat; and, with various adjuncts, such as colouring the glass of the ball A, while that of B was left white; silvering or gilding one of the balls; covering one of them with moist silk or linen, &c., this instrument became in his hands a *Photometer*, an *Æthrioscope*, a *Hygrometer*, &c.

To thermometers which depend for their action on the expansion of solids, the name PYROMETER (q. v.) is frequently given; but that of Bréguet, as delicate as a good ordinary mercurial thermometer, is not alluded to in that article. The principle of this very beautiful instrument may easily be explained thus. In bending a slip of wood, the fibres on the convex side are necessarily more extended than those towards the concave side. Conversely, if the fibres on one side of a slip of wood were to expand more than those on the other, the slip would bend. Bréguet solders together two thin strips of gold and platinum, or platinum and silver; for portability and concentration bends the compound strip into a helix, fixes its upper end, and attaches a horizontal index to the lower end. The least change of temperature in the surrounding air changes the length of one side of the compound slip more than the other, and the helix twists or untwists through an angle very nearly proportional to the change of temperature.

For measuring radiant heat, the most delicate instrument is the thermo-multiplier. See THERMO-ELECTRICITY.

THERMO'PYLÆ (literally, 'the hot gates'), a famous pass leading from Thessaly into Locris, and the only road by which an invading army can penetrate from northern into southern Greece. It lies south of the present course of the river Spercheius, between Mount Œta and what was anciently an impassable morass bordering on the Maliac Gulf. In the pass are several hot springs, from which T. probably received the first part of its name. T. has won an eternal celebrity as the scene of the heroic death of Leonidas (q. v.) and his 300 Spartans in their attempt to stem the tide of Persian invasion (480 B.C.). Again, in 279 B.C., Brennus, at the head of a Gallic host, succeeded, through the same treachery that had secured a victory to Xerxes, in forcing the united Greeks to withdraw from the pass.

THERSI'TÉS, son of Agrius, whom Homer, in the *Iliad*, makes the ugliest and most impudent talker among the Greeks before Troy. His name in antiquity was a synonym for dastardly and malevolent impudence. The later poets say that he was slain by Achilles for calumniating him.

THESAU'RUS. See DICTIONARY.

THE'SEUS, one of the most celebrated personages of the Greek heroic age. The legend of his career is differently told, but he is usually said to have been the son of Ægeus, king of Athens, by Æthra, daughter of Pittheus, king of Troezen. He was brought up at the court of his maternal grandfather, and, on reaching manhood, proceeded to his father's residence at Athens. On his way thither, he performed several famous exploits, such as the destruction of Periphetes, Sinis, Phæa, the Krommyonian sow, Skiron, Kerkyon, and the fell robber Prokrustes. See PROCRUSTES. After his arrival,

Medea sought to poison him, but her plot failed. Ægeus recognised his son, and Medea and the sons of Pallas were banished. The next feats of T. were the capture of the Marathonian bull, and the deliverance of Athens from its dreadful tribute of youths and maidens to the Cretan Minotaur (q. v.), in which he was assisted by the Cretan princess, Ariadne (q. v.). On his return to Athens, his father Ægeus destroyed himself, and T. succeeded to the throne. In his new capacity of ruler, he displayed no less wisdom than he had formerly shewn heroism. To him the legend ascribes the consolidation of the twelve petty commonwealths of Attica into one state, an event that certainly did occur at some period of Attic history, which was commemorated by the festival of the *Synœkia*. T. also reorganised the Athenaic festival, and re-named it the Pan-Athenaic, founded the Isthmian games, and many other institutions; but soon after, the craving for his old stirring life returned, and having laid down his authority, he set out along with Herakles in quest of new adventures. They fought the Amazons, and T. carried off their queen, Antiope or Hippolyte, by whom he had a son. After the death of Antiope, he married Phædra. The legend makes him take part in the Argonautic expedition by a ludicrous anachronism, join in the Calydonian hunt, help Peirithous and the Lapithæ against the Centaurs, and assist in the attempt to rescue Persephone from the lower world (which led to a long imprisonment there, from which he was delivered by Herakles). Returning to Athens, he found that the minds of the people had been prejudiced against him during his absence, and as he could not re-establish his authority, he withdrew to Skyros, where he was treacherously destroyed by King Lykomedes. What grain of historical fact may lie in the myth of T. it is hard to say. One of the most brilliant figures of the heroic age, reminding us, by his valour, wisdom, and generous love of the fair sex, of a knight of chivalry, we are loath to yield him up as a victim to the ravenous maw of criticism; yet all that can be said for his historic reality is, that so finished and admirable a prince is more likely to have been a legendary tradition of some real hero of primeval times, than a mere creature of the poetic imagination.

THE'SIS, a Greek term, strictly signifies a 'placing' or 'setting'—e. g., Pindar's *epeôn thesis* (Ode iii. 14)—the 'arrangement of words' in verse; but subsequently was employed by the philosophers (Aristotle, &c.) to denote an intellectual position that had to be maintained. This is the sense in which the word was understood by the scholastics of the middle ages.

THESMOPHO'RIA, a famous festival anciently celebrated in different parts of Greece, but especially in Attica, in honour of Demeter, as the *Thesmophoros* or 'law-giving' goddess, inasmuch as, by the introduction of agriculture, she gave the first impulse to civil society, and more especially to the honourable bond of marriage. The Thesmophoria lasted three days, from the 11th of the month Pyanepsion (October). Only married women could take part in the ceremonies. After certain preliminary purifications (among which abstinence from sexual intercourse was prominent), the women inaugurated the solemnity by marching in procession from Athens to Eleusis, where the night was spent in celebrating the mysteries of the goddess. The next day, called *nesteia*, or the 'day of fasting,' was spent in mourning. The women sat for a while on the ground around the statue of Demeter, and ate nothing but cakes made of sesame and honey. They next proceeded barefooted to the Thesmophorion or temple of Demeter, where they deposited their mystical offerings to the goddess. On the third day, called *Kalligeneia* in honour of Demeter as the 'mother of beautiful offspring,' fasting was exchanged for merriment, jollity, and raillery.

THES'PIS. See DRAMA.

THESSALO'NIANS, FIRST EPISTLE TO THE, one of the earliest epistles of St Paul—perhaps the very earliest—was probably written at Corinth about the close of the year 52 A. D., and seems to have been occasioned by the 'good tidings' which Timothy brought him of the 'faith and charity' displayed by his Macedonian converts. It may be divided into two portions, a *narrative* and a *hortatory*; the former embracing the first three chapters, and terminating with a prayer for the Thessalonians, the latter the remaining two. From the narrative portion we derive much important and deeply interesting information regarding the 'Church of the Thessalonians;' but perhaps its great value consists in the picture it presents to us of the apostle himself—'bold in God,' yet 'gentle, even as a nurse cherisheth her children;' scorning to use 'flattering words,' or to 'seek glory' from an assertion of his apostolic dignity; nay, in the excess of a noble pride, 'labouring night and day because he would not be chargeable unto any.' The Epistle is conspicuous for the absence of the ordinary doctrinal element; even the word 'justification,' it has been remarked, does not once occur: on the other hand it is penetrated with a deep conviction of the nearness of the second coming of Christ, and with an undefined fear lest, in spite of all his labours, the 'tempter' (probably, in this case, the Hellenistic Jews of Thessalonica) should seduce the Thessalonian Christians from the 'faith.' Schrader (*Apostel Paulus*) was the first to impugn the genuineness of the Epistle. He was followed in the same line by Baur; but their opinions have met with little favour among scholars of any party.—See Lünemann in Meyer's *Commentary*, Jowett's (2d ed. 1859) and Ellicott's (2d ed. 1862) *Commentaries*.

THESSALONIANS, SECOND EPISTLE TO THE, was likewise written at Corinth, and in all probability not long after the first. It is generally thought to have been occasioned by the misapprehension of the apostle's meaning on the subject of the coming of Christ to judgment, to which the previous letter had given rise, although Hug and others consider the expression, 'be not troubled . . . by letter, *as from us*' (chap. ii. 2), as indicating that somebody had forged an epistle in Paul's name; and it is scarcely possible to interpret the passage at the close of the letter, 'The salutation of Paul with mine own hand, which is the token in every epistle: so I write' (chap. iii. 17), otherwise than as a precaution against forgery. From its contents, we gather that adversaries of the apostle had been at work among his Macedonian converts, and that they had not scrupled to misrepresent his teaching, particularly on the great topic above mentioned. Who they were, we cannot be sure, but it is probable that they were Jews or Judaizing Christians. They must have obtained a considerable measure of success in their nefarious enterprise, for we are distinctly aware of a sharper and more imperious tone in the language of Paul. He now teaches more precisely that Christ could not come until the antagonistic forces in human or diabolic society had made themselves more prominent, and done their worst. The genuineness of this Epistle is as certain as that of the first. See the commentaries previously mentioned.

THESSALONI'CA. See SALONIKI.

THESSALY, the largest division of ancient Greece, lay to the south of Macedonia and the east of Epirus, being separated from the latter by Mount Pindus, and from the former by the Cambunian Mountains, the Ægean Sea bounding it on the east, and the Maliac Gulf and Mount Œta on the south. T. proper is a vast plain shut in on every side by mountains; on the N. and W. by those already named, on the S. by Mount Othrys, and on the E. by Mounts Pelion and Ossa, the only opening being the Vale of Tempe in the north-east, between Ossa and Olympus. The plain of T. is said at one time to have been a vast lake, the waters of which found an outlet by the Vale of Tempe. This plain is drained chiefly by the river Peneius (now *Salambria*), which traverses the country in a north-east direction, and its tributaries, and is the most fertile in all Greece, producing in ancient times abundance of corn and cattle, and a breed of horses considered the finest in Greece.

History. T. was originally called Æolia, indicating that the country was at one time inhabited by Æolians, who, however, were either expelled (proceeding south, and taking up their residence in Bœotia, &c.) or reduced to slavery by immigrants from the more rugged region of Epirus about 1000 B.C. As in Laconia, the inhabitants of T. appear to have been divided into three classes—1. There were the Epirote conquerors, who became rich landed proprietors; 2. Those descendants of the original inhabitants, who, although dependent on the nobles, yet possessed a few privileges—corresponding to the Laconian Periœci; and 3. The Penestæ, or those of the original inhabitants who had been reduced to serfdom, and who cultivated the lands of their conquerors, corresponding to the Helots, although, on the whole, their condition was better. These latter frequently rebelled against their masters, who were very frequently at war among themselves. Each of the four districts into which T. proper was divided was regulated by a council of its own, but they were occasionally united under a Tagus or president, whose power and time of office appear to have been indefinite. The government, from an early time, appears to have been oligarchical in the separate cities—of which Pharsalus, Larissa, Heracleum, and Pheræ were the chief—the principal power being in the hands of the two great families of the Aleuads and Scopads, famous for their hospitality and encouragement of poets and artists. T., however, never played any important part in Grecian history, and it was only after the end of the Peloponnesian war that it exercised any influence on the affairs of Greece. About that time (400 B.C.), Lycophron, overthrowing the government of the nobles, became tyrant of Pheræ, and endeavoured to make himself master of all Thessaly. What he failed to accomplish, his successor, Jason, succeeded in doing, causing himself to be elected Tagus of all T. about 374 B.C.; his assassination in 370 B.C. preventing him from attempting to become master of all Greece as he intended. The rule of Jason's successors became so unbearable, that, in 353 B.C., the old families called in the aid of Philip of Macedon, who compelled the 'Tagus' to abdicate; and, in 344, subjected the country to Macedonia, appointing as governors of the four districts members of the old families devoted to his interests. From this time, T. remained subject to the Macedonian kings, till the victory gained over the latter by T. Flaminius at Cynoscephelæ, in 197 B.C., restored it to freedom under the protection of Rome. Under the emperors, T. was united with Macedonia, but in the later constitution of the Roman Empire after Constantine it was a separate province.

THETFORD, a municipal and parliamentary borough and market-town of Norfolk, on the Little Ouse, 95 miles north-north-east of London by the Great Eastern. Malting is carried on to a considerable extent, and there is some trade on the Ouse, which is navigable up to this point. There are remains of a Cluniac priory, and of other religious edifices. The borough was disfranchised by the Reform Bill of 1867. Pop. (1881) 4034.

At T., which is a very ancient town, a synod was held in 669; and two centuries later, in 870, it was taken and sacked by the Danes.

THETIS, daughter of Nereus and Daris, was married against her will by the gods to Peleus, by whom she became the mother of Achilles. She dwelt in the depths of the sea with her father, and had, like Proteus, the power of changing her shape. Her hand is said to have been sought by Poseidon and Zeus, who gave up the pursuit on Themis declaring that the son of T. would be greater than his father.

THIAN-SHAN, or CELESTIAL MOUNTAINS, a great mountain-system, consisting of several ridges, mostly parallel, in Central Asia, are situated to the south and east of Lake Issyk-kul, in lat. about 42° N. They are said to extend in an east-north-east direction from the vicinity of Samarkand, to long. about 96° E.—a distance of 1500 miles. As this range, however, was never visited by any European till P. Semenof, commissioned by the Imperial Russian Geographical Society, explored a part of it in 1858, little has been actually ascertained regarding its character and dimensions. It is one of the four great ranges, trending in a general direction from west to east, which traverse Central Asia—and these respectively are the Altaï-Sayan, or Altaïan Mountains, in lat. about 50° N.; the T. Mountains, lat. about 42° N.; the Kuen-lun system, lat. about 36° N.; and the Himalaya Mountains (q. v.). In long. 76°—79° E., the T. Mountains are divided into two great, nearly parallel ridges, and enclose between them a deep valley, about 15 miles in average breadth, through which the river Narin—the chief head-water of the Sir-Daria—flows in a west-south-west direction. East of these ranges, the mountains are known as the Tengri-Tagh; and of this subdivision, the chief peak is the Tengri-Khan (i. e., Spectre-Prince), in lat. 42° 23′ N., long. 79° 40 E., and which rises to the height of 21,000 feet. East from the Tengri-Tagh, the T. Mountains continue in a double chain, and at an average height of 11,330 feet. In long. 90° E. is the volcano Pe-shan, which is believed to have been in activity prior to the 7th century; and in the vicinity are several other volcanoes. These are remarkable as the only instances of volcanic fires at so great a distance—1500 miles—from the sea. In long. 88° E. is the huge mountain-mass of Bogdo-Oola, perhaps the culminating point of the whole system, and certainly the peak on which there is the greatest accumulation of snow. There are several passes of from 10,000 to 13,000 feet in height.

THICK-KNEE (*Oedicnemus*), a genus of birds of the family *Charadriadæ*, most nearly allied to the plovers, although, from their comparatively large size, they have often been ranked with bustards. They differ from the true plovers in having both mandibles inflated towards the tip, and not merely the upper mandible. There are about half a dozen species. Only one occurs in Britain, the COMMON T. (*O. crepitans*), also known as the Thick-kneed Plover, Thick-kneed Bustard, Great Plover, Norfolk Plover, and Stone Curlew.

THIELT, a town of Belgium, in the province of West Flanders, 16 miles south-south-east of Bruges.

It is a well-built town, containing several interesting edifices and institutions. An important linen market takes place here annually, and the principal manufactures are linen, woollen, and cotton goods, gloves, vinegar, beer, and tobacco. The population numbers about 12,000.

THIERRY, Jacques Nicholas Augustin, an eminent French historian, was born at Blois on the 10th May 1795. He received his education in the normal school of his native town, and became a teacher in a provincial school. In 1814, he resigned this charge, came to Paris, and published his first work, entitled *De la Réorganisation de la Société Européenne*. In this treatise he considers the practicability of having one government for the whole of Europe, preserving at the same time the nationality of each people. Adopting the views of St Simon, T. became the assistant of that philosopher, in which capacity he worked for three years. In 1817, he joined Comte and Dunoyer as editors of the *Censeur Européen*, in which he wrote many articles, literary, political, and historical. In 1820, he became engaged on the *Courrier Français*, in which he published his *Dix Lettres sur l'Histoire de France*. He now began to addict himself almost exclusively to historical writing. Having given up the *Courrier*, he published his masterpiece, *L'Histoire de la Conquête d'Angleterre par les Normands* in 1825, and his *Lettres sur l'Histoire* (1827), works which had great success; but this success was dearly bought, as the necessary labour seems to have ruined the eyesight of the author. Becoming quite blind in 1830, he went in that year to Hyères for the benefit of his health. Here he met Julie de Quérengal, an authoress of considerable repute, whom he married in the following year. He seems to have been able partially to resume work about this time, and in 1835 he published his *Dix Ans d'Etudes Historiques*, the introduction to which is one of the most eloquent of his works. In 1840 appeared his *Récits des Temps Mérovingiens*, which work gained the great Gobert prize. The preface gives an interesting and eloquent account of the history of his own literary labours. His last publication was the *Essai sur l'Histoire de la Formation et de Progrès du Tiers Etat*, in 1853. The author died 22d May 1856, his wife having predeceased him in 1844. During his life T. enjoyed the success and popularity due to his industry and talents. His careful research has thrown much light on the early ages of which he has written, and dispelled much popular error regarding them. He is second to no French historian of the present day.

THIERS, Louis Adolphe, French historian and statesman, was born April 16, 1797, at Marseille. His father was a working locksmith. His mother belonged to an old commercial family, which numbered among its members Joseph and André Chénier, but which had fallen into poverty. He was placed by her relatives in the Imperial Lyceum of Marseille, where he achieved many victories over his young competitors before the year 1815, when he was sent to Aix to pursue the study of the law. Here he formed his friendship with M. Mignet the historian, in company with whom, as soon as he had taken his degree as advocate, he set off to Paris to seek his fortune. He lived for a time in obscurity and indigence, but obtaining an introduction to Lafitte, he was enrolled among the contributors to the *Constitutionnel*, then the leading Liberal organ. He became distinguished for the vigour and hardihood of his articles, and as in France the occupation of a journalist was at that time, and for many years afterwards, regarded with an estimation proportioned to its influence over society, the young political writer was admitted into the most brilliant circles of the Opposition. In the crowded saloons of Lafitte, Casimir Perier, the Comte de Flahault, the Baron Louis (the great financier of the era), and of M. de Talleyrand, he enjoyed an intercourse with actors in the grand revolutionary drama, which was eminently useful to him in the great undertaking which he had long meditated. *L'Histoire de la Révolution Française* at once placed the briefless advocate and young political writer in the highest ranks of literary celebrity. Three editions were soon called for, and the profits upon the sale, and the gift of a share in the *Constitutionnel* conferred upon him by an admirer, raised him to comparative affluence. Leaving his garret in the alley of Montesquieu, he emerged into fame, and became one of the most prominent men of France in the two paramount fields of literature and politics. In January 1830, he established a new paper of more democratic principles, the *National*. Assisted by Armand Carrel and some of the ablest men of the Liberal party, T., in this journal, waged unrelenting war against the Polignac administration, which at length, stung beyond endurance, took the desperate measure of issuing the ordinances of July. The revolution of 1830 was the result. T. now devoted himself to a public career, and was appointed Secretary-General to the Minister of Finance, and elected deputy for the town of Aix. His first appearance in the Chamber of Deputies gave no promise of his subsequent distinction. His diminutive person, his small face, encumbered with a pair of huge spectacles, and his whole exterior presenting something of the ludicrous, the new deputy, full of the impassioned eloquence of the revolutionary orators, attempted to impart the thrilling emotions recorded of Mirabeau. The attempt provoked derision, but soon subsiding into the oratory natural to him—simple, easy, vigorous, rapid, anecdotic—he became one of the most formidable of parliamentary champions. From 1832, when the Soult cabinet was constructed, he continued a minister, with one short interval, until 1836. He was by turns Minister of the Interior, Minister of Commerce and Public Works, and Minister for Foreign Affairs under various chiefs—Soult, Gérard, Mortier, and Broglie. In February 1836, he was nominated President of the Council and Foreign Minister by Louis Philippe. He only held this office until August 1836, when he passed into Opposition. In 1840, he was again called by the king to the premiership. He refused Lord Palmerston's invitation to enter into an alliance with England, Austria, and Prussia for the preservation of the integrity of the Ottoman Empire, from some lingering sympathy with the principles which dictated the first Napoleon's invasion of Egypt and Syria, and a desire to accomplish by diplomatic relations with Mehemet Ali that which Bonaparte had sought to effect by force of arms —a controlling power on the part of France in Syrian and Egyptian affairs. Lord Palmerston entered into the treaty without France, Acre was taken by the English fleet, and Mehemet Ali was driven out of Syria. The popular irritation in France fostered by T. was excessive, and nothing but the peaceful character of Louis Philippe prevented the French nation from rushing into a war of defiance to all the powers of Europe. T. alarmed the continent by his threats of setting aside the treaties of 1815, and extending the French frontier to the Rhine. It was computed that he spent not less than £8,000,000 in military and naval demonstrations. The effect of the ill blood thus generated was felt shortly afterwards in the seizure of the Society Islands, and in the remonstrances which the British government saw reason to address

to that of France respecting the ill treatment of Mr Pritchard, their consul at Tahiti. Louis Philippe dismissed his bellicose prime minister, and Europe again tasted the sweets of repose. He employed his leisure in historical pursuits. His *Histoire du Consulat et de l'Empire*, begun in 1845 and completed in 1860, is one of the greatest historical works of the age. The plan is vast and comprehensive. T. had authentic documents, and full and incomparable materials, at his disposal. War, administration, finances, the state of parties at home, and the intrigues of diplomacy abroad, are by turns grouped and distributed around some principal event which gives its name to each book. The style is easy and familiar in tone, the narrative calm and lucid, and there is little straining after colour or picturesque effect. It has been objected that there are too many military details in the work; but as it is the history of the greatest captain of modern times, it was desirable to enable even the unlearned reader to comprehend the incessant movements of troops, and the details of army organisation, which so vividly illustrate the genius and prodigious industry and activity of Napoleon I. T.'s descriptions of Marengo, and of some other great battles of the empire, are masterpieces of military history, and his narrative of the most complicated tactics is entitled to the praise of being as lucid in its explanations as it is comprehensive in its details. On the other hand, Great Britain and the other powers of Europe whose alliance ultimately caused the downfall of the empire, receive but scant justice at the hands of the historian. T. is unable to divest himself of his national feelings and prejudices, and is often the apologist and panegyrist of his hero and his policy when historic truth and impartiality would record a different verdict. His history, published in 16 vols., has been translated into most of the European languages. At the revolution of 1848 he accepted the Republic. Perceiving that Louis Napoleon aimed at imperialism, Thiers opposed him in the Chambers. After the *coup d'état* of 1851 he was arrested and imprisoned, and politely conducted to the frontier. After a year and a half he was permitted to return, Louis Napoleon having established himself in power. He resumed his historical labours. In 1863 he took the oath of allegiance to the empire. He was elected to the Chamber, and constantly spoke and acted against the emperor's ministry. He disapproved of the Crimean and Italian wars, and of the Mexican expedition, and vehemently opposed the late war with Prussia, declaring in a powerful speech that Prussia had given no cause for hostilities. He was also inimical to the treaty of commerce with Great Britain, and the free-trade policy. In Oct. 1870 he visited London, Vienna, and St Petersburg, and vainly sought aid for France against Prussia. On the 1st of Nov. he attempted an arrangement for an armistice for twenty-five days, in order to permit the elections to be held and the Constituent Assembly to be convened to ratify a treaty of peace, but without success. On the convening of a National Assembly in Feb. 1871, Thiers was, by an almost unanimous vote, chosen Executive Chief of the Republic of France, and his government was officially recognised by the English, Austrian, and Italian ambassadors. Yielding to dire necessity, terms of peace were accepted by him, the demands of Prussia being acceded to, and preliminaries signed on the 27th of Feb. During the reign of terror in Paris, the Thiers government was established at Versailles, and was reluctant at first to employ force for the suppression of the Communal revolution. But rigorous measures were finally entered upon, and after much desperate fighting, with various success, and the bombardment of Paris, the forces of the republic triumphed. T. was chosen by a very large majority 'President of the French Republic,' an office which he held till May, 1873, when Marshal MacMahon was appointed in his stead. He died September 3, 1877.

THIRLAGE is, in the law of Scotland, a peculiar right or servitude enjoyed by the proprietor of a mill over the neighbouring lands, whereby the owner or possessor of such lands is bound to carry the corn grown thereon to be ground at his mill. The miller or owner of the mill is entitled to certain duties from the suckeners, i. e., the possessors of the lands within the thirl or sucken, and these duties are called multures, being a proportion of the grain or flour. Such multures are called insucken multures; while outsucken multures are similar payments made by strangers, who are not bound to send their corn to the mill, but choose to do so. Many nice questions have been raised between proprietors on this subject; but these are technicalities which must sooner or later be abolished, and the whole system is unsuited to the present times. Thirlage is extinguished by the ruin of the mill or by forty years' exemption. In England, there is no similar right, except in some ancient manors where an immemorial custom to a like effect exists.

THIRSK, a parliamentary borough in the North Riding of Yorkshire, on both banks of the Codbeck, an affluent of the Swale, 23 miles north-west of York. It contains an old, large, and handsome Gothic church, and carries on manufactures of leather and saddlery. Pop. (1881) of borough, which returns a member to parliament, 6306.

THIRST is a well-known sensation, resulting from a peculiar state of the mucous membrane of the digestive canal, but especially of the mucous membrane and the fauces, usually caused by an insufficient supply of liquid. In cases of extreme thirst, there is a peculiar sense of clamminess in the mouth and pharynx; which, with the other disagreeable feelings, is almost immediately relieved by the introduction of liquid into the stomach, where it is absorbed by the veins. That the thirst is relieved by the absorption of the fluid, and not by its action as it passes over the mucous membrane, which seems to suffer most, is proved by the facts—(1) that injection of liquids into the stomach through a tube (in cases of wounded œsophagus), and (2) the injection of thin fluids, as water, into the blood, remove the sensation of thirst. An excessive thirst is often an important morbid symptom. It may arise from two very opposite conditions—one a condition of excitement, and the other of depression. Whenever the blood is in a state requiring dilution, and is too stimulating, as in fevers and inflammations, there is thirst; and, again, in cases of excessive secretion and exhaustion, as for example in cholera and in the two forms of diabetes, there is great thirst, which sometimes also attends the lowest stages of prostration in malignant diseases. When there is a great loss of the watery portion of the blood by profuse perspiration, caused not by disease, but by hard bodily exercise in a hot atmosphere, as in the case of coal-whippers, mowers, and reapers, &c., there is always great thirst, and from two to four gallons of beer or cider a day may, in these cases, be taken with impunity, if not with advantage. Cold tea, without milk or sugar, is the most satisfying drink under these circumstances. Independently of disease, great thirst may be induced by the use of salted meat or fish, highly-peppered curries, and other stimulating dishes, the ingestion of malt liquors drugged with salt and more pernicious matters, or of gin strengthened by sulphuric acid, &c. In all these cases, the symptoms point to the natural remedy.

THIRTY TYRANTS, at Athens, were a body of rulers invested with sovereign power after the close of

the Peloponnesian war. They were all native Athenians, but members of the aristocratical party, and chosen by the Spartan conquerors, who, knowing the animosity existing between the democracy and oligarchy of Athens, hoped to rule the city through the agency of the latter. Their government was a positive 'reign of terror,' marked by the most infamous cruelties. Even Mitford, with all his hatred of democracy, speaks of the 'shamelessness of crime' as surpassing all that had previously occurred in Grecian history. It lasted only one year, when it was overthrown by the return of the Athenian exiles under Thrasybulus.

THIRTY TYRANTS of the Roman Empire, is the collective title given to a set of military usurpers who sprung up in different parts of the empire during the 15 years (253—268 A. D.) occupied by the reigns of Valerian and Gallienus, and amid the wretched confusions of the time, endeavoured to establish themselves as independent princes. The name is borrowed from the Thirty Tyrants at Athens, but, in reality, historians can only reckon nineteen—Cyriades, Macrianus, Balista, Odenathus, and Zenobia, *in the East;* Postumus, Lollianus, Victorinus and his mother Victoria, Marius, and Tetricus, *in the West;* Ingenuus, Regillianus, and Aureolus, in Illyricum and the countries about the Danube; Saturninus, in Pontus; Trebellianus, in Isauria; Piso, in Thessaly; Valens, in Achaia; Æmilianus, in Egypt; and Celsus, in Africa.—See Niebuhr's *Lectures on Roman History*, and Gibbon's *Decline and Fall of the Roman Empire.*

THIRTY YEARS' WAR was not properly one war, but rather an uninterrupted succession of wars (1618—1648) in Germany, in which Austria, the most of the Catholic princes of Germany, and Spain, were engaged on one side throughout, but against different antagonists. This long-continued strife had its origin in the quarrels between the Catholics and Protestants of Germany, and the attempts of the former, who were the more powerful body, to deprive the latter of what liberty of worship they had obtained. The severe measures taken by the emperor, the head of the Catholic party, against the Protestant religion, led also to strictures on their civil rights; and it was to protect their political as well as their religious liberties, that the Protestants formed a union, 4th May 1608, with Frederick IV., the Elector Palatine, at its head. The rival union of the Catholic powers, under the leadership of the Duke of Bavaria, followed 11th July 1609. In Bohemia, the immense preponderance in numbers (two out of three) and influence of the Protestants, had forced from their Austrian king an edict of toleration (11th July 1609), which was at first faithfully observed; but during the reign of Matthias, sundry violations of it were made with impunity; and as the influence of Ferdinand of Styria (see FERDINAND II.), his successor, began to be felt in more flagrant partiality to the Catholics, the kingdom became a scene of wild excitement; three of the Catholic party were thrown from the window of the Bohemian council-chamber at Prague, and ultimately Ferdinand was deposed, and Frederick V., the Elector Palatine, chosen in his stead (1619); and Count Thurn, at the head of an insurgent army, repeatedly routed the imperial troops, and actually besieged the emperor in Vienna. The Catholic princes, though as apprehensive as their opponents of the encroaching policy of Austria, crowded to the emperor's aid; and while the Protestant union and James I. of Great Britain held aloof from Frederick, whose sole allies were Bohemians (under Thurn), Moravians, Hungarians, and a Piedmontese contingent of 3000 (under Count Mansfeld), a well-appointed army of 30,000, under Duke Maximilian, advanced to support the Austrians, and totally routed Frederick's motley array at Weissenberg (8th November 1620), near Prague, afterwards reducing the Upper, while an army of Spaniards under Spinola ravaged the Lower Palatinate, and the Saxons (in alliance with the emperor) occupied Lusatia. The Bohemians were now subjected to the most frightful tyranny and persecution; a similar policy, though of a more moderate character, was adopted towards the people of the Palatinate—the Protestant union standing aloof, and subsequently dissolving, through sheer terror. But the indomitable pertinacity and excellent leadership of Count Mansfeld and Christian of Brunswick, two famous partisan leaders, who ravaged the territories of the Catholic league, and the forced cession to Bethlem Gabor of large portions of Hungary and Transylvania, did much to equalise the success of the antagonistic parties.

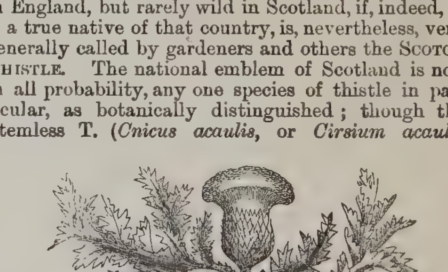
Here the war might have ended; but the fearful tyranny of Ferdinand over all the Protestants in his dominions (Hungary excepted), drove them to despair, and the war advanced to its second phase. Christian IV. of Denmark, smarting under some injuries inflicted on him by the emperor, and aided by a British subsidy, came to the aid of his German co-religionists in 1624, and being joined by Mansfeld and Christian of Brunswick, advanced into Lower Saxony, while the emperor, hampered by the political jealousy of the Catholic league, was unable to oppose him. But when, by the aid of Wallenstein (q. v.), a powerful and effective army had been obtained, and the leaguers under Tilly, in co-operation with it, had marched northwards, the rout of the Danes by Tilly at Lutter (17th August 1626), and of Mansfeld by Wallenstein at Dessau (1st, 11th, and 25th April 1626), again prostrated the Protestants' hopes in the dust; yet a gleam of comfort was obtained from the victorious raid of Mansfeld through Silesia, Moravia, and Hungary, though his scheme for an insurrection in Hungary failed, and his death soon after, at Zara, freed the emperor from a formidable and irreconcilable enemy. The combined imperialists and leaguers meantime had overrun North Germany and continental Denmark, and ultimately compelled King Christian to conclude the humiliating peace of Lübeck (12th May 1629). This second great success seems to have turned Ferdinand's head, for not content with a still more rigorous treatment of the Protestants, and the promulgation of the *Restitution Edict*, which seriously offended even the Catholics, he stirred up Poland against Sweden, and insulted Gustavus Adolphus, both personally and in the persons of his ambassadors—insolent impertinences which he soon saw bitter reasons to regret. The Catholic league now forced him to reduce his army, and supplant Wallenstein by Tilly; while France was inciting Gustavus to the willing task of aiding the Protestants in Germany.

The war entered its third phase by the landing of the Swedes at Usedom (June 1630), and their conquest of Pomerania and Mecklenburg. Gustavus, by the exercise of a little wholesome pressure, induced the Elector of Brandenburg to aid him; and though unable to save Magdeburg (q. v.), he marched to join the Saxons, completely routed Tilly at Breitenfeld (17th September 1631); victoriously traversed the Main and Rhine valleys; again routed Tilly on the Lech (5th April 1632), and entered Munich. By the judicious strategy of Wallenstein, he was, however, compelled to return to Saxony, where he gained the great victory of Lützen (q. v.); but his death, depriving the Protestants of the only man who could force the confederate powers to preserve unity

of action, was a severe blow to their cause; though the genius and indefatigable zeal of his chancellor, Oxenstierna, and the brilliant talents of the Swedish generals, preserved the advantages they had gained, till the crushing defeat of Bernard of Weimar at Nordlingen (6th September 1634), again restored to the emperor a preponderating influence in Germany. Saxony now made peace at Prague (30th May 1635), obtaining such satisfactory terms for the Lutherans, that the treaty was within three months adhered to by all the German princes of that sect, and the Calvinists were left to their fate.

Final success now appeared to demand only one more strenuous effort on the part of Austria; but Oxenstierna, resolved to preserve to Sweden her German acquisitions, propitiated Richelieu (q. v.), by resigning to him the direction of the war; and the conflict advanced into its final and most extended phase. The emperor, allied for offence and defence with the Lutherans, was now also assailed through his ally, Spain, who was attacked on her own frontier, in the Netherlands, and in Italy; Bernard of Weimar fighting independently, with the view of obtaining Alsace for himself, opposed the leaguers; while the Swedes, under Baner, held North Germany, and by frequent flying marches into Silesia and Bohemia, distracted their opponents, and prevented them, after their successes over Duke Bernard, from proceeding with the invasion of France. The great victory of Baner over the Austrians and Saxons at Wittstock (4th October 1636), restored to Sweden the victor's wreath she had lost two years before; and from this time, especially under Torstensohn (q. v.) and Konigsmark, the Swedes were always successful, adding a second victory of Breitenfeld (2d November 1642), one at Yankowitz (14th February 1645), and numberless ones of less note, to their already long list of successes, carrying devastation and ruin into the hereditary territories, even to the gates of Vienna, defeating the best generals of the empire, till, from a profound feeling of inability to check them, the Austrians hardly dared appear to the north of the Danube. On the Rhine, the leaguers at first had great success—the Weimar troops, now in French pay, were almost exterminated at Duttlingen (24th November 1643); but after the Spanish power had been thoroughly broken in the Netherlands by Condé, the French were reinforced on the Rhine, and under Condé and Turenne (q. v.), rolled back the leaguers through the Palatinate and Bavaria, and revenged at Nordlingen (3d August 1645) the former defeat of the Swedes. The emperor was now deserted by all his allies except the Duke of Bavaria, whose territories were already mostly in the hands of Turenne and Wrangel; and a combined invasion of Austria from the west and north was on the point of being executed, when, after seven years of diplomatic shuffling, with an eye to the changing fortunes of the contest, the Peace of Westphalia (q. v.) put an end to this terrible struggle.

THISTLE (*Carduus*), a genus of plants of the natural order *Compositæ*, sub-order *Cynarocephalæ*, with spinous leaves, imbricated involucres, and heads of flowers, consisting of tubular hermaphrodite florets alone, very rarely diœcious, stamens free, pappus deciduous, the receptacle having chaffy bristles. The flowers are sometimes large, generally purple, rarely white or yellowish. Recent botanists have divided this genus into two genera—the true T. (*Carduus*), in which the pappus is composed of simple hairs, and the Plume T. (*Cirsium* or *Cnicus*), in which the pappus is feathery.—The species of both genera are numerous, and are found in most of the temperate and cold parts of the northern hemisphere, annual, biennial, and perennial herbaceous plants of considerable size.—The MILK T. (*Carduus Marianus*), a biennial, native of Britain and other parts of Europe, attains a height of 4—6 feet, and is remarkable for the milky veins of its large waved leaves. The bracteæ of the involucre are subfoliaceous and recurved. The young leaves are sometimes used as a spring salad. Blanched leaves are used in winter salads. They are also used as a boiled vegetable, along with the young stalks, after these have been peeled and soaked in water to extract part of their bitterness. The root is used as salsafy. In former times, the plant was frequently cultivated.—The Canada thistle (*Cirsium arvense*, or *Cnicus arvensis*), a species about 1—3 feet high, with creeping roots, pinnatifid leaves and numerous diœcious flowers, is a very troublesome weed in fields, very common in Britain, and now too common, not only in Europe, where it is indigenous, but in America and other countries to which it has found its way. *Cirsium lanceolatum* and *C. palustre*, both common British plants, are also regarded as troublesome weeds. The former has larger flowers than any of the other species common in Britain. *Cirsium oleraceum* is a native of the north of Europe, but not of Britain, distinguished by its yellowish flowers, which are surrounded with large yellowish involucral bracteæ. The young leaves are used as a culinary esculent.—The BLESSED T. (*Carduus benedictus* of the pharmacopœias, *Cnicus benedictus* or *Cirsium benedictum* of modern botanists) is a native of the Levant and of Persia, resembling in appearance a *Centaurea*, with yellow flowers enveloped in leaves, and abounding in a gossamer-like down. The whole plant has a very bitter and disagreeable taste, and, besides a bitter extractive, contains much sulphate and muriate of potash and sulphate of lime. It is a powerful laxative-tonic medicine, and a strong decoction of it readily induces vomiting.—The COTTON T. (*Onopordon*) is a distinct genus, known by its receptacles being destitute of bristles, and coarsely and deeply honey-combed. The common Cotton T. (*O. acanthium*), a native of Europe, and found in England, but rarely wild in Scotland, if, indeed, it is a true native of that country, is, nevertheless, very generally called by gardeners and others the SCOTCH THISTLE. The national emblem of Scotland is not, in all probability, any one species of thistle in particular, as botanically distinguished; though the Stemless T. (*Cnicus acaulis*, or *Cirsium acaule*)



Stemless Thistle (*Cnicus acaulis*).

is in many districts of Scotland so designated. According to the common tradition, the Danes (or Norsemen?) came upon the Scots unperceived in the dead of night; and, halting while their spies were trying to discover the undefended points of their opponents' camp, one of the spies chanced to tread upon a thistle of this species, and the loud imprecation which the sudden pain evoked aroused the unsuspecting Scots, who at once attacked the invaders, gained a complete victory and dubbed the plant which had been the means

of their success, the Scotch Thistle. The Cotton T. has large elliptic leaves, and a broadly winged stem. The young fleshy root and the stem, whilst still tender, are in many places boiled and eaten. The expressed juice of the plant was formerly reckoned good for cancerous sores and cutaneous eruptions. —Plants of the genus *Silybum*, distinguished by its monadelphous stamens, and of the genus *Echinops*, which has a very different manner of growth, and belongs to a very different section of the *Compositæ*, are often to be seen in flower-gardens, where they are known as Thistles. The name is also, generally with some addition, very often bestowed upon many plants which have little resemblance to any of these, except in their spinous character. *Centaurea cyanus* is commonly known as the BLUEBOTTLE.—There are numerous species of Thistle (*Cirsium*) natives of the United States, among which *C. Virginianum*, *horridulum*, *altissimum*, and *muticum* are most common.

THISTLE, ORDER OF THE, called also the Order of St Andrew (q. v.). The following is a more accurate account of the institution of the order than is given in the article referred to: The order is of no very ancient date. The earliest-known mention of the thistle as the national badge of Scotland is in the inventory of the effects of James III., who probably adopted it as an appropriate illustration of the royal motto, *In defence*. Thistles occur on the coins of James IV., Mary, James V., and James VI.; and on those of James VI. they are for the first time accompanied by the motto, *Nemo me impune lacesset*. A collar of thistles appears on the

Star Collar and Badge of the Order of the Thistle.

gold bonnet-pieces of James V. of 1539; and the royal ensigns, as depicted in Sir David Lindsay's armorial register of 1542, are surrounded by a collar formed entirely of gold thistles, with an oval badge attached. This collar, however, was a mere device until the institution, or, as it is generally but inaccurately called, the revival of the order of the Thistle by James VII. (II. of England), which took place on May 29, 1687. Statutes were issued, and eight knights nominated by James; but the patent for the institution of the order never passed the Great Seal. After falling entirely into abeyance during the reign of William and Mary, the order was revived by Queen Anne, December 31, 1703.

THISTLEWOOD CONSPIRACY, a conspiracy formed in 1820 by Arthur Thistlewood, a man of profligate habits, and a few other adventurers of desperate fortunes, to overturn the government of Britain, and assassinate the ministers of the crown. The opportunity was to be taken of the funeral of George III., when all the military would have left London for Windsor, to take possession of London, and plunder the shops. The ministers were to be massacred when assembled at a cabinet dinner, and the pieces of cannon in Gray's Inn Lane and the Artillery Ground were at the same time to be seized. A provisional government was to be established, and means taken to intercept communication with Windsor and Woolwich, and prevent any one from leaving England by sea. The conspirators were surprised, and most of them apprehended by the police in the garret in Cato Street, where their meetings were held, on February 23, the same day which had been fixed for the massacre of the ministers. A few turned king's evidence against the rest; and Thistlewood and four others suffered the penalty which the law annexed to treason.

THO'LEN, an island in the Netherlands, province of Zeeland, bounded on the S. by the Easter Scheldt, contains about 34,000 acres of rich land, and is defended from floods by strong dykes, the borders of which are planted with trees. Pop. 14,078. Wheat, rye, barley, oats, beans, and potatoes are extensively grown. The annual produce of madder reaches a million of pounds-weight, and of flax, 400,000. Horses, cattle, sheep, and swine are kept in large numbers. Tholen, the chief town, with a pop. of 2540, is situated in the south-east corner of the island.

THOLUCK, FRIEDR. AUG. GOTTREU, a German Protestant theologian, whose reputation is perhaps greater in England and America than at home, was born at Breslau, March 30, 1799, and studied, first, at the university of his native city, and afterwards at Berlin, where oriental studies claimed his special regard, the first-fruits of which was his *Suffismus sive Theosophia Persarum Pantheistica* (Berl. 1821). The state of his religious opinions may be conceived from his own confession, that when he left Breslau, he thought nearly as much of Mohammedanism as of Christianity. The influence of Neander, however, and still more of Baron von Kottwitz, a philanthropic Christian nobleman of Silesia, produced a radical change in his convictions and modes of thought, and as early as 1823, he appeared as a champion of evangelical doctrines in his *Wahre Weihe des Zweiflers* (True Consecration of the Sceptic; 7th ed. published at Hamb. 1851, under the title of *The Doctrine of Sin and the Propitiator*, and translated into English, French, Danish, Swedish, and Dutch). Next year he published his *Auslegung des Briefs an die Römer* (Exposition of the Epistle to the Romans; Berl. 1824; 4th ed. 1842; also translated into English and other languages). About the same time he was appointed Extraordinary Professor of Theology at Berlin; and in 1825, he paid a visit to England. On his return, in 1826, he succeeded Knapp as Ordinary Professor of Theology at Halle, where, with the exception of a brief official sojourn at Rome, he remained until his death. T.'s position at Halle was far from pleasant at first, for the majority of the theological faculty, among whom was Gesenius, were very decided rationalists, and did all in their power to make the new professor miserable; but the latter, though not a man of very powerful intellect, was filled with a quiet, earnest, resolute *faith*, and he continued his evangelical

labours in spite of all opposition, until they were crowned with success. The university of Halle is at present, mainly owing to T., as thoroughly Christian, though not, perhaps, so strictly orthodox as it was in the days of Francke. His kindness (and that of his wife) towards students, especially *poor* students, was proverbial, and contributed not a little to his fame abroad. In 1843 he was chosen a member of the Magdeburg Consistory. Tholuck's fertility as an author was remarkable. Besides the works already mentioned, we may specify among his exegetical writings his *Praktische Commentar zu den Psalmen* (Practical Commentary on the Psalms; Hamb. 1843); *Commentar zum Evangelium Johannis* (Commentary on the Gospel of John; 6th ed., Hamb. 1844); *Commentar zum Briefe an die Hebräer* (Commentary on the Epistle to the Hebrews; 3d ed. Hamb. 1850); and *Philosophisch-theologische Auslegung der Bergpredigt* (Philosophico-theological Exposition of the Sermon on the Mount; 3d ed. Hamb. 1845). Of his dogmatic writings, the principal are contained in the *Literarische Anzeiger für Christliche Theologie und Wissenschaft*, a journal now discontinued; and in his *Glaubwürdigkeit der Evang. Geschichte* (Credibility of the Gospel History; Hamb. 1837), a treatise directed against Strauss's *Leben Jesu*. Among his contributions to history of theology, are to be reckoned his *Vermischte Schriften grösstentheils apologetischen Inhalts* (2 vols., Hamb. 1839); *Der Geist der Luth. Theologen Wittenbergs im 17 Jahr* (The Spirit of the Lutheran Theologians of Wittenberg in the 17th Century; Hamb. 1852); *Das Academische Leben des 17. Jahrh.* (The Academic Life of the 17th Century; Halle, 1853—1854); and his *Geschichte des Rationalismus* (History of Rationalism), published in several parts and completed in two divisions. Besides these may be mentioned several volumes of sermons on the leading doctrines of the Christian faith, published at different times. He died at Halle, July 3, 1877.

THOMAS, JOSEPH. See SUPP. in Vol. X.

THO'MAS, ST, one of the most westerly of the group of Virgin Islands, is situated in lat. 18° 20′ N., long. 65° W.; area (*Almanach de Gotha*, 1866), 23 sq. m.; pop. about 13,000. It belongs to Denmark.

The interior of the island is mountainous, and not very fertile. Since the emancipation of slaves in 1847, the cultivation of sugar has been entirely abandoned. Cotton is planted, but only in small quantity. The climate is hot, dry, and unhealthy; yellow fever is endemic, and preys much upon Europeans, the natives being seldom affected by it.

The principal town, Charlotte Amalie, is situated on the side of the mountain, and descends nearly to the margin of the harbour. The houses, which appear from the harbour tier above tier, and have a beautiful and picturesque effect, are built of a bright cream-coloured limestone, surrounded with balconies, verandahs, and jalousies, fancifully painted, and the roof covered with galvanised iron or shingles (the latter gaily coloured when brightened up with the rays of a tropical sun), and presenting at night, when lighted up with lamps, a very striking effect. The town itself is laid out with rather narrow streets, but there are some good stores and hotels in the place. The governor's house, to the east of the town, is a large and imposing building; and an ancient ruin, 'Blue Beard's Castle,' crowns an elevation. The harbour is land-locked on three sides; the entrance to it, fortified on both sides, is rather narrow. The harbour is spacious, and has deep water, is much occupied with shipping of many nations, and has been much improved since 1864 by dredging. The Royal Mail Steam-packet Company have made it a central station for their large steamers, from whence the intercolonial steamers diverge on their different routes through the adjoining seas. In the year 1864, 714 British vessels of all kinds, exclusive of ships of war and mail-packets, entered the harbour. The value of the British manufactured goods imported in 1864 was £700,000.

THOMAS, CHRISTIANS OF ST, a remarkable religious community settled from a very early date on the Malabar coast of the Indian peninsula. They take their name from the apostle St Thomas, who, according to a very ancient tradition, for which, however, no very positive evidence or satisfactory authority can be alleged, preached in India, and is regarded as the apostle of that country. As early as the 6th c., the well-known voyager, Cosmas Indicopleustes, reports of numerous Christian communities settled in India, under the pastoral care of bishops sent from Persia. To this circumstance it may be attributed that the Indian Christians, like those of what may be called the mother church of the Persian kingdom, lapsed into the Nestorian heresy, which, after the decrees of Ephesus and Chalcedon, having been suppressed by the civil laws of the Roman Empire, was driven beyond the limits of Roman authority, and found its most favoured seat among the hostile Persians. Once established among the people, these opinions continued to be professed by the Christians who survived in those regions the vicissitudes of the revolutions of which India in medieval times was the scene. Their seat was almost entirely along the Malabar coast, and extended from the south cape, Comorin, as far as Calicut; and they are found scattered throughout this length over the whole space from the western declivity of the Ghauts to the sea. From the time of their lapsing into Nestorianism, their bishops were ordained by the Nestorian patriarch of Babylon, and they possessed certain civil rights under the successive dynasties which ruled in the south of India. On the whole, however, they were much oppressed; and on the arrival of the Portuguese in 1598, the Christians of St T., although Nestorians, regarded them as their deliverers. Nevertheless, the diversity of creed was at once recognised by the western missionaries, and attempts were made by the successive bodies of missionaries, Franciscans, Dominicans, and finally Jesuits, to reconcile them to the Roman Church. A union, more or less real, was effected by a synod held at Diamper in 1599; and one of the Jesuit Fathers, Padre Roz, was named bishop in 1601. This union, however, was not lasting; they fell away once again from the Roman communion, and the expulsion of the Portuguese from Cochin by the Dutch completed the disruption. A considerable number of them, however, were again united to Rome through the missionaries of the Carmelite order; and towards the close of the 17th c., the Emperor Leopold I. obtained the leave of the Dutch to send a bishop and twelve priests of that order to the Malabar coast. One of the most serious impediments to the influence of those missionaries, as well with the schismatics as with the heathen, was found in the intrigues and jealousies of the Portuguese. In later times, the Christians of St T. have for the most part been absorbed in the native Christian population. Their tenets were in the main those of the Nestorians of Chaldea and Mesopotamia, about the precise details of which much controversy has prevailed, and many conflicting statements have been made, according to the religious views of the various travellers or missionaries who have reported regarding them. Much of this conflict of testimony arises from a confusion of names rather than of things. See NESTORIANS.

THOMASIUS, Christian, a German philosopher and jurist, was born at Leipzig, 1st January 1655, studied at Frankfurt-on-the-Oder (1675—1679), and returning to his native town, commenced to lecture on law in a style perfectly free from the pedantry of the schools. In 1687, to the astonishment of his Latin-speaking colleagues, he adopted the German language as the vehicle of his expositions, published his programme for the following year in the same tongue, and commenced a monthly journal under the very German title of *Freimüthige, lustige und ernsthafte, jedoch vernunft- und gesetzmässige Gedanken oder Monatsgespräche über allerhand, vornehmlich aber neue Bücher* (Honest, Merry, Sincere, yet Rational and Moderate Thoughts, or Monthly Talk concerning all Sorts of Books, but especially new Ones). This work, however, excited so much opposition that he was forced to leave Leipzig, and went first to Berlin, and afterwards (1690) to Halle, where, under the patronage of the Brandenburg court, his lectures were the means of establishing a university, since famous. In this university T. became Professor of Jurisprudence, and here he died, 23d September 1728. The great aim of T. was to harmonise and blend science and life; hence his contempt for hair-splitting subtleties of which nothing could be made; his preference for the use of German rather than Latin in his academic lectures; his disinclination to all philosophical terminology, his depreciation of the schoolmen, &c. But more particularly he was among the first who insisted on dissociating natural right from morality, and in connection therewith, honourably signalised himself as a courageous opponent of trial for witchcraft and punishment by torture. The characteristic features of his mode of thought are contained in his *Vernünftige und Christliche aber nicht scheinheilige Gedanke und Erinnerungen über allerhand auserlesene, gemischte, philosophische und juristische Händel* (Rational and Christian, but not pretendedly Pious Thoughts and Recollections concerning sundry Choice, Mixed, Philosophical, and Juristic Transactions, 3 vols., Halle, 1723—1726); and in his *Geschichte der Weisheit und Thorheit* (History of Wisdom and Folly).—See Luden, *Christian Thomasius nach seinen Schick-salen und Schriften* (Berl. 1805).

THO'MASTON, a town and port of Maine, U. S., on the St George River, 15 miles from the coast, and 80 miles east-north-east from Portland. Its extensive granite quarries are worked by the convicts of the state prison; 300,000 casks of lime are exported annually; registered shipping, 60,000 tons; 5 churches, 2 public libraries. Pop. (1880) 3017.

THO'MISTS. See Aquinas.

THOMSON, James, author of *The Seasons*, was born on the 11th September 1700, at Ednam, in Roxburghshire, of which parish his father was minister. He was put to school at Jedburgh, and afterwards sent to complete his education at Edinburgh. His intention was to enter the church, and he went through a full course of study with that object in view. His views, however, changed. From a very early age, he had been wont to express himself in verse; and in 1725 he betook himself to London, to seek fame and fortune as a poet. Almost his sole capital for the enterprise seems to have been his manuscript poem of *Winter*. This, with some little delay and difficulty, he disposed of to a publisher for three guineas; and as its success was not instant, his outlook was by no means brilliant. Gradually, however, the merits of the poem were recognised; successive editions were called for; friends and patrons were not wanting to the young author; and in no long time T. found himself as good as a made man and poet. The *Winter* was followed in 1727 by the poem *Summer; Spring* was published the year after; and *Autumn*, completing *The Seasons*, appeared in 1730, with a reissue of the previous portions. In 1729, T. produced the tragedy of *Sophonisba;* but though great expectations were formed of it, its success on the stage was but indifferent. A weak line which occurred in it—

O Sophonisba, Sophonisba, O,

as parodied by a wag in the pit into

O Jemmy Thomson, Jemmy Thomson, O,

afforded much merriment to the town, and somewhat killed the pathos of the author, otherwise with not much vitality in it. During 1730—1733, T. was abroad in Paris and elsewhere with the son of Sir Charles Talbot, the Chancellor; and on his return, at the death of his pupil, the comfortable place was bestowed upon him of Secretary of the Briefs. This he held till it lapsed, on the death of the Chancellor in 1737, which left him once more in considerable straits, which were, however, a little alleviated by a pension of £100 a year given him by the Prince of Wales. His tragedy of *Agamemnon*, produced in 1738, was, in Johnson's phrase, 'only endured, but not favoured;' and his poem on *Liberty*, by himself considered his greatest work, was little relished by the public. His *Tancred and Sigismunda*, produced in 1745, was the only one of his tragedies which had any success, and its success was not of a signal kind. About this time, the accession to power of his friend Mr Lyttleton secured him the office of Surveyor-general of the Leeward Islands, which, however, he did not long live to enjoy. He died of a neglected cold in August 1748, and was buried in the church of Richmond, without an inscription; but a monument was afterwards erected to his memory in Westminster Abbey. In the spring before his death he had published his finest poem, *The Castle of Indolence.* This piece, which is written in the Spenserian stanza, has all the descriptive power and opulence of imagination which distinguish his more popular *Seasons*, while in tone and diction it is much more chastened and harmonious. Together, they continue to maintain for T. a somewhat high place in the roll of British poets. Of his other works, with the exception of the song of *Rule Britannia*, nothing but the names is now remembered. As a man, T. was singularly amiable, and his careless, indolent generosity of disposition seems to have endeared him to all who knew him.

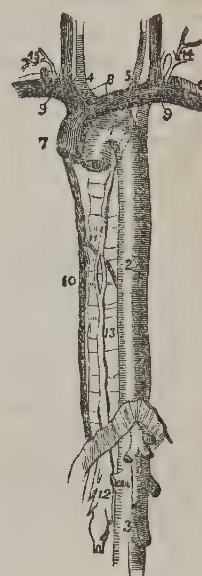
THOMSON, Sir William, one of the greatest living mathematicians and natural philosophers, was born in June 1824. His father was Professor of Mathematics in the university of Glasgow. T. graduated in 1845, as second wrangler and first Smith's prizeman at Cambridge, where he was shortly afterwards elected to a fellowship in St Peter's College; and became Professor of Natural Philosophy in the university of Glasgow in 1846. This appointment he still holds. While still an undergraduate, he published several valuable papers. He was for some time editor of the *Cambridge Mathematical Journal*, and some of his most brilliant discoveries have appeared in its pages. He has also contributed to the *Comptes Rendus, Liouville's Journal de Mathématiques*, the *Philosophical Magazine*, the Transactions and Proceedings of the Royal Societies of London and Edinburgh, and various other journals. All his numerous writings have the stamp of originality in a marked degree. In the mathematical theories of Elasticity, Heat, Electricity, and Magnetism, he has made remarkable discoveries; among which we need merely mention the Dissipation of

Energy, the beautiful idea of Electric Images, and the complete solution of the problem of telegraphing through a submarine cable. Besides this analytical work, he has made extensive and valuable experimental investigations, both alone and in conjunction with Joule (q. v.). Popularly, he is best known by his association with the Atlantic cable, a gigantic idea, which but for his investigations might perhaps not have been attempted. He has invented several excellent and useful instruments for various electrical purposes; instruments for the determination of electric units in absolute measure, &c.; and in July 1866, as Consulting Electrician to the Telegraph Construction and Maintenance Co., he assisted for the second time in the successful laying of an Atlantic cable. In 1870 he published a very remarkable paper, in which he arrives at a proof of the absolute magnitude of atoms, and which attracted marked attention in Europe and America. See *Leisure Hour* for August 1871.

His elder brother, JAMES, now Professor of Civil Engineering in Queen's College, Belfast, has made various improvements in the construction of Turbines (q. v.) and other engines; but is best known in science by his discovery that the freezing-point of water is lowered by pressure; and the glacier theory he has founded upon it. See HEAT, ICE, REGELATION.

THOR, the god of thunder, was the son of Odin and Earth (Yörd); his wife was Sif (= *sib*, friendship, love, and thus of the same import with Freyja). His palace, supported on 540 pillars, was called Thrudwanger; here he received the warriors that had fallen in battle. Thunder was caused by the rolling of his chariot, which was drawn by he-goats. He was in the vigour of youth, had a red beard, and was the strongest of all gods and men; the gods even called in his assistance when they were in straits. He was, in particular, a terror to the Giants (q. v.), with whom he was perpetually at strife, and whom he struck down with his hammer Miolnir (i. e., the smasher or mauler), which had the property of returning to his hand after being hurled; it had been made by cunning dwarfs. The sign of the hammer was among the heathen Teutons analogous to that of the cross among Christians. In the contest at the twilight of the gods, T. slew the serpent of Midgard, but fell at the same time poisoned by the venom exhaled from its mouth. The name of T. was widespread. The Saxons worshipped him as Thunar (High-German, *Donar*). Torden, the wrathful deity dreaded by the Lapps, who in his rage hurled down huge blocks from rocks, tore up trees, destroyed cattle and men, is evidently the Scandinavian Thor. The Gallic god Taranis—in an old inscription Tanarus—mentioned by Lucan, appears also to be identical, especially as *taran* in the Celtic languages still signifies thunder. The attribute of thunder is intimately associated with the Latin Jupiter and the Greek Zeus (see also INDRA). Of all the Asa-gods, T. had unquestionably the most worshippers. In Upsala, according to Adam of Bremen, he occupied the place of honour in the temple between Odin and Frikke. In Norway, T. was the national god, and here, as in Iceland, temples were almost exclusively erected to him. Offerings were made to him, particularly in times of pestilence. On the ground of the superior respect enjoyed by T., and of his being called 'Old Thor,' some place him in opposition to Odin, and consider him historically as an older divinity, only partly supplanted by the Odin doctrine. As rude force is the predominating element in T., the humorous element of the Scandinavian belief attaches to him. Thus, the giants often blinded him by magic, and made fun of him; yet he always shews his extraordinary strength in these cases, and in the long-run his opponents are invariably overcome by the hammer. Thursday is so called from T.; and the name survives in numerous names of places (Thuneresberg, in Westphalia; Thunderhill, in Surrey; Thurso), and also in personal names (Thorburn, in Scand. Thorbiörn).—Compare Uhland, *Der Mythus von Thor* (Stutt. 1836); Grimm, *Deutsche Mythologie.*

THORA'CIC DUCT, a canal equal in diameter to a goose-quill, proceeding from the *Receptaculum Chyli* (into which the contents of the lacteals are collected, and which is situated in the front of the body of the second lumbar vertebra), ascends along the front of the vertebral column, between the aorta and ascending vena cava, as high as the fourth dorsal vertebra; it then inclines to the left, and passing behind the arch of the aorta, ascends as high as the seventh cervical vertebra.



The Course and Termination of the Thoracic Duct.

1, the arch of the aorta; 2, the thoracic aorta; 3, the abdominal aorta; 4, arteria innominata; 5, the left carotid; 6, the left subclavian; 7, the superior vena cava, formed by the union of 8, the two venæ innominatæ; and these by the junction 9, of the internal jugular and subclavian vein at each side; 10, the vena azygos; 12, the receptaculum chyli; 13, the thoracic duct, often dividing in the middle of the thorax into two branches, which soon reunite (the course of the duct behind the great vessels is shewn by a dotted line); 14, the duct making its turn downwards before terminating in the veins of the left side; 15, the termination of the trunk of the duct on the right side.—From Wilson's *Anatomist's Vade-mecum.*

when it bends forwards and downwards, and terminates at the point of union of the subclavian and internal jugular veins of the left side, where it is provided with a pair of semilunar valves, which prevent the admission of venous blood into it. It is also provided with other valves on its upward course. This duct is not liable to any special diseases; but if its function of conveying chyle from its source into the general circulation be interfered with, as, for example, by the pressure of a tumour, the due nutrition of the system must be more or less interfered with.

THO'RAX. See CHEST.

THORI'NUM, or THO'RIUM (symb. Th; equiv. 115·72), is a rare metal, much resembling aluminium, but taking fire considerably below a red heat, and

burning with great briliancy. *Thorina*, or *Thoria*, is supposed to be the protoxide, and is remakable for its high specific gravity, 9·4. Thorinum was discovered in 1829 by Berzelius in an earth to which he had given the name *Thorina*, and which occurs in a rare black Norwegian mineral termed *Thorite*. None of the compounds of this metal are of any practical importance.

THORN. See Cratægus, Hawthorn, and Spine.

THORN (Pol. *Torún*), a strongly-fortified town of Prussia, in the south of the province of Prussia, on the right bank of the Vistula, 31 miles east-south-east of Bromberg by railway. The town was founded in 1232, was a member of the Hanseatic League, and contains many houses—as the town-hall—remarkable for their beautiful gables and interiors. It is the birth-place of Copernicus, whose monument is to be seen in the *Johannis-Kirche*, and a bronze statue to whom was erected in the market-place in 1853. An active trade in corn and timber is carried on. Pop. (1880) 20,614.

THORN, Conference of, one of those efforts to explain away the differences between the several bodies of Christians, with a view to religious reunion, of which the 17th c. furnishes more than one example. The originator of this movement was the king of Poland, Ladislaus IV., who proposed his project for the consideration of a synod of the bishops of his kingdom held at Warsaw in 1643, and letters were addressed in consequence to all the several religious bodies in Poland, inviting them to send delegates to an assembly to be held at Thorn, for the purpose of the mutual explanation of their doctrines, with a view to the removal of all differences of belief. The conference met in October 1645, and was opened in a spirit of moderation; but it soon lapsed into disputation and controversy, and at length broke up without any result, November 21, 1645. The official account of the proceedings of the conference are printed in Calvi's *Historia Syncretistica*.—See also Schröckh's *Kirchengeschichte seit der Reformation*, iv. p. 509.

THORN-APPLE (*Datura*), a genus of plants of the natural order *Solanaceæ*, having a tubular 5-cleft calyx, a large funnel-shaped 5-lobed flower, a 2-laminated stigma, and an imperfectly 4-celled, prickly, or unarmed capsule. The species of this genus are annual herbaceous plants, rarely shrubs or trees; and are in general very narcotic, and productive of excitement or delirium. The common Thorn-apple, or Jamestown Weed (*D. stramonium*), is an annual plant, with smooth stem and leaves, white flowers, and erect prickly capsules, a native of the East Indies, brought by the gipsies to Europe, where it is now very generally to be met with, as also in Asia, the north of Africa, and North America. It is by some stated to be the plant from which the poisonous 'dri' of the gipsies is obtained. It contains a peculiar narcotic alkaloid, *Daturine*, and is one of the most powerful narcotic acrid poisons; but its leaves and seeds are employed, although rarely, in medicine. The leaves have an extremely nauseous overpowering smell, and a loathsome bitter taste; the seeds, which are of a dark-brown colour, are still more poisonous. A variety with pale violet flowers and purplish violet stem is frequently cultivated in gardens as an ornamental plant.—Still more narcotic is the Soft-haired Thorn-apple (*D. metel*), a native of the south of Asia and of Africa. Robbers in India employ it in order to stupefy those whom they would rob, or rather to throw them into the condition of a waking dream. From its seeds, along with opium, hemp, and certain spices, a strong intoxicating substance is prepared, which the Mohammedans of India use in order to produce in themselves an indescribable joyfulness and extremely pleasurable feeling for a short time; but the use of

Common Thorn-apple (*Datura stramonium*).

it destroys the constitution. *D. Tatula*, another Indian species, has similar properties, and is very energetic; as is also *D. sanguinea*, the Floripondio of Peru, which is used by the Indians to prepare a very powerful narcotic drink, which stupefies when very diluted, and when strong, brings on maniacal excitement.—The beautiful *D. fastuosa* has flowers externally of a violet colour, and white within, and is cultivated as an ornamental plant, especially a variety with what are called double flowers, which consist rather of two corollas, one within the other.—*D. arborea*, a native of Peru and Colombia, has begun to be also very generally cultivated in flower-gardens in Europe. It has very splendid pendulous white flowers, 9—12 inches long, which diffuse a sweet smell in the evening and at night.

THORNBACK (*Raia clavata*), a species of ray or skate, common on most parts of the British coast. It attains a large size; the muzzle is little produced, and the form is nearly rhombic; the tail has two small membranous fins near the tip, on the

Thornback (*Raia clavata*).

upper central ridge, and a small dilatation at the tip. The upper surface is brown, with lighter spots; the under surface white. The upper surface is

rough with small points, and has numerous nail-like crooked spines, each with an oval bony base. The T. is much esteemed for food, particularly in autumn and winter, but is most abundantly captured in spring and summer, when it approaches the shore to deposit its eggs.

THOROUGH BASS. See FIGURED BASS.

THORWALDSEN, BERTEL, one of the greatest of modern sculptors, was born, it is supposed, at Copenhagen, on the 19th November 1770. Neither the place nor the day of his birth, however, can be fixed with absolute certainty; and he himself, when casually questioned as to the last, replied with a certain *brusque* felicity: 'I don't know; but I arrived at Rome on the 8th March 1797;' dating his birth, as it were, from the commencement of his career as an artist. He was the son of a poor ship-carpenter, and his first essays in art were made in the carving of figure-heads in the yard where his father worked. His education was otherwise neglected, so that through life he could but indifferently write or spell; but the genius for art was born with him, and in 1793 he gained the first gold medal for design at the Academy of Copenhagen; and along with it the privilege of three years' residence abroad for the purpose of study. Accordingly, in 1796, he sailed for Rome, arriving there as stated above. After long obscure and patient labour, his talent became conspicuous. From the celebrated Canova, in particular, he had early and generous recognition; and shortly, by the model for his great work, 'Jason,' he secured general admiration. No purchaser could, however, be found for it till, in 1803, just as in hopeless disgust the artist was about to return to Copenhagen, he received from the well-known Thomas Hope an order for its production in marble at a price which might be called munificent. From this time forward, prosperity and fame flowed upon him in full tide. In 1819, he returned to Denmark, taking the overland route, and everywhere on his journey special honour was paid him. His reception in Copenhagen was triumphal, and apartments were assigned him in the palace of Charlottenburg. He remained at home but a year, and at the end of it returned to Rome, where he continued to prosecute his art assiduously, up to 1838, when he left it, intending to pass his remaining years in his native country. Its climate, however, proved no longer suitable to him, and the year 1841 found him once more at Rome. In 1844, having revisited Copenhagen, he died suddenly there in the theatre, of disease of the heart, on the 24th March. All the works remaining in his possession he bequeathed to his country, to be preserved in a museum bearing his name, for the maintenance of which he also left the bulk of his fortune, reserving a sufficient provision for Madame Poulsen, his natural daughter. This magnificent and unique collection is now one of the chief glories of the metropolis of his native country. By his countrymen, he is naturally held in special honour; and their proud verdict, which ranks him the greatest of sculptors since Michael Angelo, is elsewhere more generally acquiesced in than is often the case in such instances of national enthusiasm. Anything like a catalogue of his chief works need not be here attempted. He addicted himself by preference to classical and mythological subjects; but his great works in the cathedral of Copenhagen, 'Christ and the Twelve Apostles,' 'St John preaching in the Wilderness,' and the 'Procession to Golgotha,' sufficiently prove that he was determined to this preference by no incapacity to appreciate and grandly fulfil the demands of the Christian ideal. Of the many busts from his hand of eminent contemporaries, those of Byron and the great Danish poet Œhlenschläger are perhaps the most notable. The life of T. has been written by Hans Christian Andersen, also by J. M. Thiele of Berlin. Of M. Thiele's work, a careful abridgment, by the Rev. M. R. Barnard, was not long since published by Messrs Chapman and Hall, London; and this is as yet the only authoritative source of information in detail available for the English reader.

THOTH, also called TAUT or THEUTH, the Egyptian Hermes or Mercury, the mythical inventor of the arts and sciences, music and astronomy, and especially of speech and hieroglyphs or letters, over which he was supposed to preside. His name, indeed, meant 'speech,' or 'word,' and he personified the divine Logos, or intellectual power. See HERMES, EGYPT.

THOU, JACQUES AUGUSTE DE, or, as his name is frequently written, Jacobus Augustus Thuanus, son of Christophe de Thou, first president of the Parlément de Paris, was born in that city on the 8th October 1553. He was originally designed for the church, but when old enough to judge for himself, he gave up all thoughts of an ecclesiastical career. In spite of the difficulty presented by a sickly constitution, he pursued both literary and scientific studies with vigour and success. Taking a liking for the writings of Cujacius, he took up his residence at Valence in Dauphiné, where he attended the lectures of the celebrated jurist. At Valence, he made the acquaintance of Scaliger, with whom he maintained an unbroken friendship for the rest of his life. In 1578, he accepted, with reluctance, the office of ecclesiastical councillor of the Parlément of Paris. A firm adherent of royalty, in 1588, he was made councillor of state to Henry III.; and during the rest of the reign of that king, he took a leading part in all public affairs. On the accession of Henry IV., he was made keeper of the royal library. In 1593, he began his great work, the *Historia sui Temporis*, which principally occupied him during the remainder of his life. He took an important part in the arrangement of the Edict of Nantes; but, with this exception, he seems to have given but little attention to public affairs during the reign of Henry IV.; and the death of that monarch, in 1610, may be said completely to have ended his political existence. From 1604, when the first 18 books of the history appeared, the author held the position of first historian of his age. Eighty books appeared during his life; and the remainder, forming in all 138 books, were published in 1620, after the author's death, which took place on the 7th May 1617.

As a historian, T. is eminently impartial; so devoid, indeed, did his work shew him to be of religious prejudice, that he incurred the imputation of having no religion about which to feel; the consequence being that, in 1609, his work was put into the *Index Expurgatorius*—a fact which appears to have distressed him more than one would have expected. Written in Latin, the author has spared no pains to make it severely classical. It is generally held valuable rather from its workmanship than its material. The best English edition is that by Samuel Buckly, 7 vols. 1733. T. also wrote a number of Latin poems.—See *Autobiography*, ending 1601; also Colinson, *Life of Thuanus* (Lond. 1807).

THRACE, anciently the name of an extensive country bounded on the N. by the Danube, on the E. by the Euxine, on the S. by the Ægean and Macedonia, and on the W. by Macedonia and Illyria. In pre-historical times, however, the name

appears to have denoted the whole of eastern Europe north of Greece, including both Macedonia and Scythia; so, at least, one is disposed to understand the fable, that Oceanus had four daughters—Asia, Libya, Europa, and Thracia. It is, on the whole, very mountainous—whence, perhaps, its name T., from *tracheia*, rugged (?)—the principal range being Hæmus (mod. *Balkan*, q. v.), from which three lesser chains branch off in a south-easterly direction, the loftiest being Rhodope, the summits of which reach an elevation of more than 8000 feet. The three most important rivers of T. are the Strymon (mod. *Struma*), which, during the Greek period, formed the boundary between it and Macedonia; the Nestus (mod. *Carasu*); and the Hebrus (mod. *Maritza*, q. v.), the largest—all of which flow southward from Hæmus into the Ægean Sea. Roughly speaking, ancient T., before the rise of the Macedonian power, comprised the territory now divided by the Turks into the provinces of Rumili and Bulgaria; but subsequently the Romans made the range of Hæmus the northern limit of T., and gave the region between Hæmus and the Danube the name of Mœsia (mod. *Bulgaria*). The climate was considered by the Greeks very severe—even that of Ænos, on the shores of the Ægean, being described by Athenæus as 'eight months of cold and four months of winter;' but it is believed that the ancient accounts are much exaggerated, or are only applied to T. poetically as the *North*, though it is not to be denied that, in the mountainous districts, the frost was often intense—as is still the case. The country was marshy, undrained, and overspread with dense damp forests (of fir, oak, chestnut, &c.), which must have considerably lowered the temperature; but large portions, especially in the south and east, 'such as the great plain of Adrianople and the land towards the lower course of the rivers Nestus and Hebrus,' were very fertile. The chief products were corn, millet, wine, and hemp. Cattle, sheep, horses, and swine were reared in great numbers. The region between the Nestus and the Strymon appears to have been infested by lions. Herodotus states that they attacked the baggage-camels of Xerxes on his march; but if this was anciently the case, these formidable animals have long since disappeared. Gold and silver mines were numerous and productive in the same locality, and the acquisition of these was the principal motive for Philip of Macedon's aggressions.

The question has been much discussed, to what race the Thracians belonged, and it cannot be said that it has as yet been satisfactorily settled. It is certain, however, that two different peoples went by this name in early times. It is repeatedly asserted by those writers who treat of the confused medley of tradition and myth which fills up the pre-historical annals of Greece, that a race of 'Thracians' inhabited part of the Hellenic peninsula, and had even at one time extended themselves as far as Attica. To these pre-historic Thracians belonged, says Strabo, the Muses, and the cultivators of ancient music, Orpheus, Musæus, Thamyris, and Eumolpus; and the grand argument against confounding them with the Thracians of history, is the impossibility of a race so notoriously barbarous as the latter in language and manners, having sprung from the authors of Hellenic literature and art (see Müller's *Hist. of Greek Lit.*, p. 26, *et seq.*). But whether the pre-historic Thracians were properly Hellenes, or 'Pelasgians'—whatever *that* may mean—is indeterminable.

Passing now to the historic Thracians, whom we find settled in the regions north and east of Macedonia, we are again at fault. Of their manners and customs, of their character, and of their later history, we indeed know something; but of their origin and ethnological relations, we cannot be said to know anything. They were not Greeks, for they spoke a language which the latter called barbarous: but if (as Strabo asserts) the Getæ and Daci were branches of the Thracian family, and spoke the same tongue, we may conjecture that, ethnologically, the term 'Thracians' denotes a mixed Illyrico-Scythian race; though it is quite impossible, from want of evidence, to substantiate the conjecture. Herodotus, Xenophon, and Strabo are our chief authorities regarding the habits and practices of the people. From them we learn that they bought their wives, and sold their children. Polygamy was general, and when a husband died, his favourite spouse was slain over his grave. Before marriage the Thracian women enjoyed the utmost liberty; after it, they were guarded with Turkish rigour. War and robbery were the only honourable occupations of the men. They lived to steal, either from each other or from neighbouring peoples. When not fighting or plundering, they spent their days in savage idleness, or in quarrelling over their cups. Courageous, or rather ferocious, after the fashion of barbarous peoples, they yet lacked the steady valour and endurance of disciplined troops; at all times, their warfare displayed more fierceness and impetuosity than fortitude. Their treachery was probably no greater than that of other barbarians.

The history of T. may be sketched in a few words. The Greeks first became acquainted with the inhabitants when they began to plant colonies on the coasts. Of these, the principal were Byzantium (675 B.C.), Selymbria, Abdera (560 B.C.), Mesembria, Dicæa, Maronea Ænus, Cardia, Sestus, Amphipolis, &c.; but their want of union—the fatal weakness of Hellenic civilisation—hindered them from acquiring that measure of power to which they might have otherwise aspired, and enabled the Thracian chiefs of the interior to preserve their independence. In 513 B.C., Darius, king of Persia, marched through T. on his way to punish the European Scythians, and on his return, left Megabazus, with 80,000 men, to subdue the country. In this he partially succeeded, but new disturbances and complications arose between the Persians and Greeks, which resulted (480 B.C.) in the famous expedition of Xerxes, the details of which do not belong to Thracian history. We have only to mention that a consequence of the expulsion of the Persians from Europe was the resumption of liberty and the revival of prosperity among the Greek colonies in Thrace. Shortly before the Peloponnesian War, a native Thracian state—the Odrysian—had attained to great power and eminence under a ruler named Sitalces, who joined the Athenian alliance, but could not, in spite of his resources, prevent the triumph of Sparta in the north as well as in the south. The rise of the Macedonian kingdom, under Philip II. (359 B.C.), destroyed the independence of great part of Thrace. All the region between the Strymon and Nestus was incorporated with Macedonia, and Macedonian garrisons were established further east. Under the government of Lysimachus, the subjugation of T became complete. On the fall of the Macedonian kingdom (168 B.C.) it passed into the hands of the Romans, and subsequently shared the vicissitudes of the Roman Empire. In 334 A.D., a colony of Sarmatians was planted in T. by Constantine, and in 376, another of Goths by permission of Valens. In 395, it was overrun by Alaric, and in 447, by Attila. In 1353, Amurath obtained possession of all its fortresses, except Constantinople, and it has ever since remained in the hands of the Turks.

THRASHING is the separating of the grain or seeds of plants from the straw or haulm, a process which has been accomplished in different ages and countries by means less or more effective. The first method known to have been practised was the beating out of the grain from the ears with a stick. An improvement on this method was the practice of the ancient Egyptians and Israelites to spread out the loosened sheaves of grain on a circular piece of hard ground 50—100 feet in diameter, and to drive oxen backwards and forwards over it, so as to tread the grain out; but as this mode was found to damage a portion of the grain, it was partially superseded in later times by the thrashing-sledge (Egypt. *noreg*, cf. Heb. *moreg*), a heavy frame mounted on three rollers, which was dragged over the heaps of sheaves. The use of the stick was, however, retained for thrashing the lighter kinds of grain. Similar methods of thrashing were employed by the Greeks and Romans, the stick (*fustis*, *baculum*, *pertica*), the treading by men or horses, and the thrashing-sledge (*tribulum*) being found in common use among them; but their thrashing-sledge, which is still to be seen in operation in Greece, Asia Minor, Georgia, and Syria, differed from the eastern one by having pieces of iron or sharp flints fastened to the lower side, in place of rollers. The primitive implement in Northern Europe was the stick, and an improved modification of it, the *flail*, has not yet been completely superseded. The flail consists of two sticks loosely fastened together at one end by stout thongs (*caplins*), one stick (the *hand-staff*) is used as a handle by the workman, and by a circular swing round his head he brings down the other stick (the *swiple*) horizontally on the heads of the loosened sheaves spread out on the barn-floor. In the hands of a good workman, this implement is found to perform its work pretty effectively, although slowly.

Various attempts were made to supersede the flail by a machine, but with little success, till 1787, when Andrew Meikle, an ingenious Scotch mechanic, produced a thrashing-mill so perfect, that even after having run the gantlet of nearly a century of improvers, it is essentially the machine of its original inventor. In Meikle's mill, the mode of operation is as follows: The sheaves are loosened and spread out one by one on the feeding-board A (fig. 1), with the ears towards the machine; they

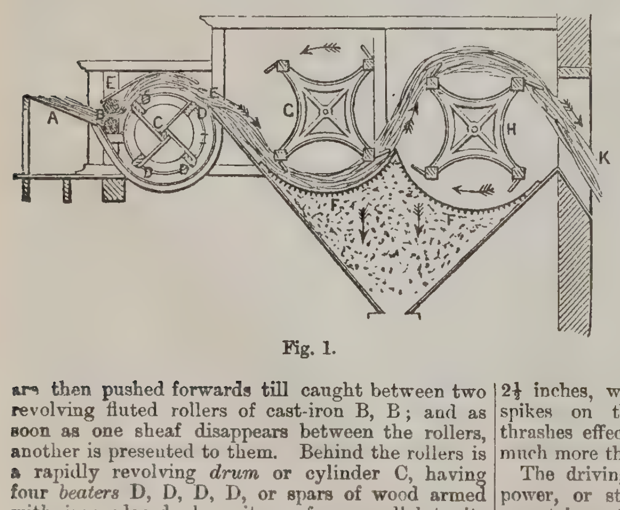


Fig. 1.

are then pushed forwards till caught between two revolving fluted rollers of cast-iron B, B; and as soon as one sheaf disappears between the rollers, another is presented to them. Behind the rollers is a rapidly revolving *drum* or cylinder C, having four *beaters* D, D, D, D, or spars of wood armed with iron placed along its surface parallel to its axle; and these beaters striking the heads as they are protruded from between the rollers, detach the seeds and husks. In order to render this, the important part of the process, more effective, the drum is provided with a cover, E E, which keeps the straw subjected to its action; and as the drum revolves many times more rapidly than the rollers, each portion of straw receives a succession of buffets from the beaters before the rollers quit hold of it. Grain and straw then pass together over the cylinder, the former falling through the wire-work F, F, while the straw is carried forward by the circular rakes G, H, and being by them thoroughly tossed and separated from the grain and chaff, is ejected at K. The grain which has fallen through the wire-work is received into a winnowing-machine, where it is cleansed from chaff, &c., and is then either discharged upon the barn-floor, or, as is the case with the most improved machines, is raised by a series of buckets fixed on an endless web, and again winnowed, to separate the perfect grains from the light and small seeds. Barley is, previous to the second winnowing, subjected to the process of 'hummelling,' by which the awns are removed; but the rest of the process is the same as above.

Since Meikle's invention, the improvements attempted on his mill have been chiefly confined to modifications of the drum; such as diminishing the distance between the drum and its cover, increasing the number of the beaters, and accelerating the speed of the drum (to about 800 revolutions per minute).

The portable thrashing-machine, so generally employed in England, is devoid of the two grooved rollers, the loosened sheaf being at once submitted to the action of the thrashing-machinery; the drum, which is a *high-speed drum* (sometimes cased with iron), is provided with six beaters, and its cover, which encloses about one-third of its circumference, is capable of being set at any required distance from it by means of screws. In this form of mill the straw revolves at once with the drum, and being rubbed between its beaters and the cover, the grain is effectually separated; hence this species of drum is frequently called the *rubbing-drum*. More work can be done by this machine than by Meikle's ordinary mill, but the machinery is more liable to be injured than when the fluted rollers are employed, as these latter, to a certain extent, regulate the 'feeding-in.' A modification of the latter machine has the drum wide enough to allow of the straw being fed in sideways; the cover encloses the machine for about three-fifths of its circumference; and the straw, after separation from the grain, is delivered by the rakes almost unbroken, and in a condition fit for being at once put up in *bolts*, or bundles, whence this species of drum is called a *bolting-drum*. The defects of this form are: the slowness of its operation, the corn requiring to be fed in thinly; the greater power required; and the increased tendency to clog, especially if the straw is somewhat damp. In another form, the drum is armed with rows of spikes projecting outwards for about 2½ inches, which revolve between similar rows of spikes on the interior of the cover; this kind thrashes effectually, but breaks and chops the straw much more than the other forms of drum.

The driving-power is either wind, water, horse-power, or steam; the first of which is so very uncertain and unequal in its operation, that it has now-a-days been mostly superseded by the others.

Water-power is always desirable, and when it can be had in sufficient quantity or regularly, which is but seldom, is much to be preferred to the others in point of economy, its mode of application to thrashing being either by the ordinary machinery of the Water-wheel (q. v.) or by *Barker's Mill* (q. v.). Horse-power was the agent in most common use

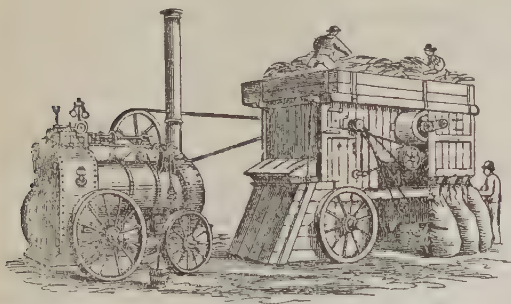

Fig. 2.

till recently, the horses being yoked to beams attached to a vertical revolving shaft which communicated motion by means of bevelled gear to the thrashing-machine. *Tread-power*, on an endless chain platform, is preferred to the *sweep-power*, as it can be used in restricted spaces, as barns, &c. At the present time steam-power, as being more economical, has in some districts superseded horse-labour, engines of 4—10 horse-power being generally employed. Portable thrashing-mills and engines are very generally employed in England and to some extent in the United States, being thought by many to be more economical. In the wheat-fields of the Mississippi Valley these machines are made to traverse the field, strewing the straw behind them and gathering the wheat into bags. The fixed machine is advocated by others on the grounds of the various additional uses that can be made of it, its diminished liability to derangement, and its greater cheapness. See *Transactions of the Highland Society*, March 1852.

THRA'SIMENE, Lake. See Trasimenus Lacus.

THREAD is an exceedingly small twine made by doubling and twisting several thicknesses of yarn so as to produce a strong and well-rounded line for sewing with, either of cotton, flax, or silk.

THREAD-WORMS. This term is employed by some zoologists to the whole order *Nematoda*—a word derived from the Greek, and signifying a thread-like form. Most writers, however, restrict it to the *Oxyuridæ*, which, in the early part of this work, have been included in the *Ascarides* (q. v.), but have been arranged in a separate family by Cobbold, who divides them into ten genera. Only one species, *Oxyuris vermicularis* (formerly known as *Ascaris vermicularis*) (q. v.), the small thread-worm, infests man, and is the commonest of the intestinal parasites.

THREATS, in a legal sense, are that kind of intimidation which has for its object to influence a person in abandoning or surrendering some legal right, or what is equivalent, paying money, to prevent some injury being done to him. When the threats are made by more than two persons, the offence usually assumes the form of Conspiracy (q. v.). In other cases, the usual form of the offence is the sending of a threatening letter—i.e. a letter either anonymous or otherwise—demanding money from the party addressed; otherwise, that he will be murdered, or his house will be burned, or he will be charged with some infamous crime. Whoever sends, or indirectly or directly, with knowledge of the contents, causes to be received, any letter or writing demanding, with menaces, or without any reasonable or probable cause, any property, chattel, money, valuable security, or other valuable thing, is held guilty of felony, and liable to penal servitude for life, or imprisonment for three years. And whoever demands such things with intent to steal the same, is also guilty of felony, with like punishment. So whoever sends a letter threatening to accuse a person of any crime, with a view or intent to extort money or gain any valuable security or property, is guilty of felony. Whoever threatens to accuse one of an infamous crime with intent to extort money, or gain some valuable property, is also guilty of felony. Whoever sends a letter threatening to burn or destroy any house, barn, building, stack of grain or hay, or to kill or wound cattle, is guilty of felony.

THREE KINGS, Feast of the, a famous medieval festival, identical with Epiphany (q. v.) or Twelfth Night, and designed to commemorate the visit of the three magi or wise men of the East (transformed by the mingled ignorance and reverence of the middle ages into great kings) to the infant Saviour. But the name is more particularly given to a kind of dramatic or spectacular representation of the incidents recorded in the 2d chapter of Matthew—as, the appearance of the wise men in splendid pomp at the court of Herod, the miraculous star, the manger at Bethlehem, the solemn and costly worship of the Babe—which was long very popular. In 1336, a peculiarly gorgeous representation was got up at Milan by the Preaching Friars. See Chambers's *Book of Days*, vol. i., page 62.

THRIFT (*Armeria*), a genus of plants of the natural order *Plumbagineæ*, having the flowers collected into a rounded head, a funnel-shaped dry and membranous calyx, five petals united at the base, five distinct styles, and five stamens attached to the base of the petals. By many botanists it has been regarded as a subdivision of the genus *Statice*, from which it is distinguished chiefly by having the

Common Thrift (*A. maritima*).

flowers in heads.—The Common Thrift (*A. maritima* or *vulgaris*) is a plant which grows in turf-like tufts, with linear leaves, scapes a few inches high, and beautiful rose-coloured flowers, an ornament of the

sea-coasts of Britain and of Europe generally, and also frequently found on high mountains. It is often planted in gardens as an edging, for which it is very suitable, being of a fresh green all the year, and exhibiting its fine flowers in profusion in July and August; but it requires to be renewed every two or three years, the smallest rootless sets growing, however, with great readiness in the moist weather of spring. The flowers are an active and useful diuretic. From two drachms to an ounce of the flowers freshly gathered and quickly dried, should be gently boiled, and the patient allowed to drink as much of the decoction as he pleases. Some aromatic, as anise or cinnamon, is added.

THRIPS, a genus of small insects of the order *Hemiptera*, sub-order *Homoptera*, allied to *Aphis* (q. v.), and included in the family *Aphidii* of some entomologists. The species are numerous, and widely distributed. They are very active, and some of them very troublesome, by the injury which they do to cultivated plants, upon the juices of which they live. When disturbed, although they use their wings, their motion resembles leaping rather than flying. The wings are much fringed. A common British species is *T. cerealium*, an insect not a line in length or in extent of wing, which resides in the spathes and husks of cereal grasses, particularly wheat and rye, in the beginning of summer, causing the grain to shrivel; and which at an earlier season of the year, causes the abortion of the ear by puncturing the stems above the joints. It is most injurious to late-sown wheat, probably because the plants are weak, and therefore easily injured, at the time when the *Thrips* abounds. The larva is deep yellow, part of the head and two spots on the thorax dusky. The pupa is pale yellow and active. The perfect insect is flat, smooth, and pitch-colour. The male is wingless, the female winged.

1, *Thrips cerealium; a*, natural size. 2, do. with wings extended; *b*, natural size.

THROAT, Affections of the. Common inflammatory sore throat has been already described in the article Quinsy; and other important throat-diseases, Aphthæ or Thrush, and Diphtheria, have also been discussed in special articles. The *malignant sore throat* of the older nosologists is now recognised as a modification of scarlatina. Another important variety of sore throat occurs as one of the forms of secondary syphilis. *Bronchocele* or *Goitre*, which, to a certain degree, is an affection of the throat, is specially described under the latter name.

The disease popularly known as *Clergyman's Sore Throat*, or *Dysphonia Clericorum*, and which is recognised in medicine under the name of *Follicular Inflammation of the Pharynx*, first shews itself by huskiness of the voice, with more or less coughing, hawking, and expectorating, from an uneasy sensation in the throat; there is, moreover, a constant inclination to swallow. On examining the back of the throat, its mucous membrane is seen covered with granulations, caused by an accumulation of secretion in the follicles, which sometimes burst and discharge their contents, which are of an elastic consistent nature. This discharge is occasionally followed by ulceration. The disease commonly arises from too prolonged or powerful exercise of the voice by persons in whom the mucous membrane of the throat is in a relaxed condition. Perfect rest from public speaking, preaching, acting, &c., is of more importance than anything else in the way of treatment, and a residence during the winter and spring in a mild and equable climate is expedient. Torquay, Ventnor, Nice, Mentone, Algiers, and Egypt, afford a choice of suitable residences. Tonics, such as iron, quinia, and strychnia (in small doses not exceeding $\frac{1}{20}$th of a grain, three times a day), should be tried; but the local application of a strong solution of nitrate of silver (from 20 to 80 grains in one ounce of distilled water), applied by a probang to the affected mucous membrane, is usually of far more service than internal remedies. The best work on this subject is that of Dr Horace Green, an American physician.

Passing over several throat-affections of minor importance, we proceed to the consideration of wounds in the throat. These wounds are comparatively seldom the result of accident; they are more often made with a murderous intent, and most frequently they are made with the view of committing suicide.

The first duty of the surgeon, in treating a case of cut throat, is to arrest the flow of blood. Ligatures should be applied to wounded arteries, and steady pressure with the finger (beneath which a small pad of lint is placed) to wounded veins, such as the external jugular. If the internal jugular is wounded, fatal hæmorrhage will very rapidly ensue, unless the wound is immediately plugged with small pieces of sponge, or pressure with the finger is maintained as long as necessary. With a knowledge of these means of checking hæmorrhage by pressure, an intelligent non-professional person may be the means of saving life. When the bleeding has completely ceased, but not till then, means may be taken for bringing together the edges of the wound. In most cases, sutures, or even adhesive plaster, are inexpedient and even dangerous, and it is best to keep the parts in simple apposition. 'The patient,' says Mr Gray, 'should be placed in bed in a moderately warm room, the shoulders well raised by pillows, and the head bent forward and retained in that position by a bandage, and the wound should be covered with a strip of wet lint or linen.'

THROMBO'SIS (derived from the Greek *thrombos*, a clot of blood) is a term originally suggested by Virchow, and was generally employed to designate an affection of the blood-vessels (either veins or arteries), which essentially consists in a coagulation of blood (forming a true clot) at a certain fixed spot. Under certain morbid conditions, the blood has a tendency to coagulate in its vessels during life, on the least provocation. Thus, slight pressure on the side of a vein will sometimes induce this coagulation, while in other cases it is due to inflammation of the tissues which surround a vein, or laceration of a vein (as when the placenta is expelled from the uterus). A clot thus formed in a vessel increases and extends from one to another, till it reaches and finally fills a large vessel. Clots of this kind occurring in veins have been noticed from the times of Ambrose Paré and Petit, who seem to have been the first to apply the term *thrombus* to them.

THRO'NDHJEM (Drontheim), the ancient Nidaros, and former capital of Norway, is situated in the Fjord of T., at the mouth of the little river Nid, 240 miles—direct line—north of Christiania; pop. (1875) 22,544. T., which consists of the old town, founded in 997, and the suburbs of Blakland and Ilen, is built on the picturesque and undulating slopes of the Nid-Elv. and has regular and broad

streets. The fortified islands of Munkholm and Christiansteen defend the capacious harbour, which is never closed by frost on the seaward side. Among the public buildings the most noteworthy are the Kongens-Gaard, or old palace, and St Olaf's Church, the remains of the old cathedral, or Christ Church, which was built in the 12th c. by Archbishop Oeysteen, who erected this noble Gothic pile on the site of the two early Christian churches which had been founded by Harald Haardrade and Olaf II. The fine western extremity of the nave was not completed till 1248. The body of the murdered St Olaf was preserved within a costly shrine in the chancel of Christ Church, which ranked as the metropolitan church of Norway, where the kings of Norway have been crowned since the time of Magnus V. (1164). T. is the seat of government for the province and of a bishopric, and has a public exchange, the principal national bank, a public library, museum, various literary and scientific institutions, an institution for the deaf and dumb, an insane asylum, &c. The chief articles of trade are fish, tar, deal, and copper, which is obtained from the neighbouring mines of Röros. Salted cod and herrings, which are found in large quantities at the entrance of T. Fjord, are important articles of export. Besides its shipping and coasting trade, T. is the centre of considerable manufacturing activity, and has good sugar-refineries, distilleries, &c. The environs of T. are picturesque, and its position is one of considerable attraction, notwithstanding the high northern latitude (63° 25′); while the numerous historical events with which it is associated render it one of the most interesting towns in the Scandinavian kingdoms. The preponderance of wooden houses has somewhat diminished of late years, and the local authorities are endeavouring to enforce the use of stone for building purposes, in consequence of the frequent occurrence of great fires.

THRONE (Gr. *thronos*), the chair of royalty, an ornamented seat raised above the level of the floor on which it stands, often covered with a canopy, and intended for the use of a sovereign or other potentate. From an early period the Asiatic monarchs are represented as enthroned: the same usage of a dignified chair set apart for the sovereign was adopted in Greece, where also it was customary to represent all the greater gods as enthroned. In the middle ages and modern times, the throne has been in all monarchical countries the chair occupied by the sovereign on state occasions. The name of throne was also given, in the early centuries of the Christian church, to the raised seat in the middle of the tribune behind the altar, where the bishop sat surrounded by his clergy. The throne is now a common metaphorical expression for sovereign power and dignity.

THROSTLE. See SPINNING.

THROW, the term applied in Mining to the amount of Dislocation (q. v.) in a vertical direction, produced by a fault in the strata.

THRUSH (*Turdus* or *Merula*), a genus of birds of the family *Merulidæ* or *Turdidæ*, having a bill of moderate size, straight, the upper mandible convex, its point compressed, notched, and slightly curved downwards, the gape furnished with a few hairs; the nostrils near the base of the bill, oval, partly closed by a naked membrane; the first feather of the wing very short, the third and fourth longest; the tarsus longer than the middle toe, the outer toe connected with the middle toe at the base. The species are numerous and widely distributed, some of them inhabiting temperate and even cold countries, and some found only in tropical regions. Some of them are birds of passage, as the fieldfare and redwing. Some are gregarious, particularly in winter, as the species just named; others live solitary or in pairs. The common British species are the Black-bird (q. v.), Fieldfare (q. v.), Redwing (q. v.), Ring Ouzel (q. v.), Song T., and Missel Thrush.—The SONG T., or THROSTLE (*T. musicus* or *M. musica*), the mavis of the Scotch, is smaller than

Song Thrush (*Turdus musicus*).

the black-bird, its whole length being not quite nine inches. Its plumage is brown, of various finely-mingled shades; the throat, sides of the neck, breast, and flanks yellowish, spotted with dark brown; the belly nearly white, with a few spots of dark brown; a dark brown streak, with a lighter brown streak over it, passing from the bill to the eye. It is found in all parts of Europe, but deserts some of the northern parts in winter, being thus partially a bird of passage. It remains all the year in Britain. It feeds on insects, worms, slugs, snails, berries, and seeds. It often makes its nest in the centre of a thick bush or shrub, and sometimes in an open shed. The eggs are usually four or five in number. The male takes part in the work of incubation, and is very attentive in feeding his mate whilst so occupied. The throstle is well known as one of the sweetest songsters of the groves. In captivity, it is easily taught simple airs.—The MISSEL T. (*T. viscivorus* or *M. viscivora*) is about 11 inches in entire length,

Missel Thrush (*Turdus viscivorus*).

and is the largest and strongest European species of the genus. The plumage is very similar to that of the Song Thrush. The tail is slightly forked, which is not the case in that species. The spots on the belly are more numerous, and black. The song is loud and clear, but not equal to that of the Song T. or of the black-bird. The bird delights in pouring forth its song from the very top of a tall tree. It also very often sings before or during wind and

rain, whence it has received the name of Storm-cock. Its nest is generally fixed in the fork of a tree. It is found in almost all parts of Britain where there are woods. Its range extends through great part of Asia; it is found in India.—The WOOD T. (*T. mustelinus* or *M. mustelina*) is abundant in North America in summer, as far north as Hudson's Bay, retiring to tropical and subtropical regions in winter. It is rather smaller than the Song T., and very similar to it. It is of a very shy and retiring disposition. It has a clear but very simple song, which is to be heard in the depths of the forest, far from the haunts of men. Several other species are found in North America. India has some.—A common West Indian species (*T.* or *M. leucogenys*) is familiarly known by the name of Hopping Dick, and is a general favourite from its bold, lively manners, and its sweet song. All the species are in esteem for the table, and the Song T. is much sought for this use in Italy in the season of ripe grapes, when it becomes very fat. Gardeners in Britain well know how troublesome thrushes are where numerous, from their avidity for cherries and small fruit.

THRUSH, known also as *Infantile Sore Mouth*, is essentially a disease of early infancy, although it may occur at any age. Its characteristic symptom is the presence of small roundish white specks or patches on the lining membrane of the cavity of the mouth and throat, on the surface of the tongue, the angles of the lips, &c. These patches, which are termed *aphthæ*, look like minute drops of tallow or fragments of curd, and are formed by elevated portions of epithelium covering a drop of serous fluid; and as the dead epithelium falls off, a raw surface, or a dirty ash-coloured spot, is left exposed. In thrush, crops of these little patches commonly succeed one another. These spots render the mouth hot and tender, in consequence of which the act of sucking is accompanied by difficulty and pain. In association with these local symptoms are indications of general constitutional disturbance, such as feverishness, drowsiness, sickness, flatulence, colicky pains, diarrhœa, &c. The stools are green and slimy, and not unfrequently acrid, as may be inferred from redness of the anus being a common symptom. The vomited matters are also green, and have a strongly acid smell, as also has the breath. The complaint sometimes seems to be the result of improper diet, if the child is being brought up by hand, or of unwholesome milk from a diseased or intemperate nurse; of bad ventilation, &c.; but in some cases the cause of the disease is not evident. The disorder usually lasts eight or ten days, and is only attended with danger when the local affection runs into a low form of gangrenous ulceration. As undue acidity of the stomach seems to be an almost general symptom, the diet should be carefully regulated, and mild *antacids* prescribed. Dr (now Sir Thomas) Watson specially recommends a mixture of 2 parts of dried carbonate of soda and 1 of gray powder (mercury with chalk), of which from three to five grains may be given thrice daily. As a local application to the patches, honey of borax may be applied with a camel-hair pencil; or a pinch of a mixture of powdered borax and loaf-sugar (1 to 8 or 10) may be placed occasionally on the tongue, and the infant allowed to spread it over the mouth.

THRUSH, or TRUSH, in the horse, consists in inflammation and ulceration of the sensitive surfaces within the frog, giving rise to a fœtid discharge, constituting unsoundness, and usually causing lameness. Want of cleanliness is the chief cause. Daily, when the horse returns to his stable, the foot should be washed out with soap and water, carefully dried, and the fissures filled with mineral tar. If amendment does not speedily ensue, a dressing of calomel should be substituted for the tar several times a week. Ragged or loose portions of the frog may be removed by the knife or scissors.

THUCY'DIDÉS, the great historian of the Peloponnesian War, born of the demus Halimus most probably in 471 B.C., is said to have been the son of Olorus and Hegesipyle, and connected with the family of Cimon. It is stated—on authority equally conjectural, however—that he was instructed in oratory by Antiphon, and in philosophy by Anaxagoras. Certain it is that, Athenian as he was, of good family, and resident in the most cultivated community in Greece, he must have enjoyed a most liberal education. He was further possessed, either by inheritance or by acquisition through marriage, of gold-mines in that part of Thrace lying opposite the island of Thasos. He left a son called Timotheus, and perhaps also a daughter, who is said by some scholars to have written the eighth book of his history. We know from himself that he was one of the sufferers from the terrible plague of Athens, and also one of the few who recovered. We have no direct evidence as to his having displayed in public the oratorical talent which he reveals in his history; but it is certain that he held military command, and that he had under him an Athenian squadron of seven ships at Thasus, 424 B.C., when Eucles, who commanded in Amphipolis, solicited his assistance against Brasidas. The expected arrival of a superior force induced Brasidas to offer Amphipolis favourable terms, which were accepted. T. arrived on the evening of the same day on which Amphipolis had surrendered; and though he prevented Eion, at the mouth of the Strymon, from falling into the enemy's hands, still his failure to save Amphipolis caused him to be sent into exile, probably to avoid the severer punishment which his enemy Cleon, then so popular with the Athenians, was designing for him. Where his exile was spent, is not known. Probably he lived a good deal in the Peloponnesus, if not also in Sicily, as has been inferred from his minute descriptions of Syracuse and its neighbourhood. According to his own account, he lived in exile twenty years, and probably returned to Athens about the time when Thrasybulus liberated it, in the beginning of 403. Ancient authorities are all agreed that his end was a violent one, though whether it occurred at Athens or in Thrace, we have no means of ascertaining. The year of his death is generally fixed at 401. Uncertainty also prevails as to the time when he wrote his history. He is supposed, from hints supplied by himself, to have kept a register of the events of the war, from its outbreak to its close. His great work, chronologically divided into winters and summers—each summer and winter making a year—was subsequently re-arranged, probably by Alexandrine critics, into the books and chapters as we now have it; and of these books the eighth (and last) is supposed either to have not been written by him, or to have not received the same careful revision which he bestowed on the previous seven. There is hardly a literary production of which posterity has entertained a more uniformly favourable estimate than the history of Thucydides. This high distinction he owes to his undeviating fidelity and impartiality as a narrator; to the masterly brevity of his style, in which he is content to give in a few simple yet vivid expressions the facts which it must have often taken him weeks or even months to collect, sift, and decide upon; to the sagacity of his political and moral observations, in which he shews the keenest insight into the springs of human action, and the mental nature of man; and to the unrivalled

descriptive power exemplified in his account of the plague of Athens, and of the Athenian expedition to Sicily. Often, indeed, does the modern student of Greek history share the wish of Grote, that the great writer had been a little more communicative on collateral topics, and that some of his sentences had been expanded into paragraphs, and some of his paragraphs into chapters. But this want cannot have been felt by the contemporaries of T., while the fate of other ancient historians warns us that had his work, like theirs, been looser in texture, or less severely perfect, it would not have survived, as it has done, the wearing influence of time, or remained, in its own language, the *ktema es aei*—the 'possession for ever'—it has proved to the world. The best editions are those of Poppo (11 vols., Lps. 1821—1840), of Krüger (2 vols., Berl. 1846—1847), and—at least for historical illustration—of Arnold (3 vols., Oxford, 1830—1835). It has been admirably translated into English by the Rev. Thomas Dale.

THUG (from the Hindustani *thaga*, deceive; hence, literally, a deceiver, a cheat) is the name of a religious fraternity in India, which, professedly in honour of the goddess Kâlî, the wife of S'iva, is addicted to the committal of murders, and chiefly lives upon the plunder obtained from its victims. The name of Thugs is that by which this fraternity is generally known among Europeans in the more northern parts of India. In some provinces to the southward, they are called *Phansigars*, or 'stranglers' (from the Hindustani *phansi*, a 'noose'). In the Tamil language, their name is *Ari Tulukar*, or 'noosers;' in the Canarese, *Tanti Kalleru*, or 'thieves who use a cat-gut noose;' and in Telugu, *Varla Vandla*, or 'people who use the noose.' In the south of India, they used to live under the protection of the native chieftains, who, on the consideration of a settled contribution, and probably also of a share in the result of their depredations, connived at their practices, which, to the uninitiated, were generally concealed under the guise of an honest industry, especially that of the culture of land.

The proceedings of the Thugs are generally these: Banding together in gangs of from ten to fifty, but sometimes also of a much greater number, they assume the appearance of ordinary traders, travelling, if enabled to do so by their wealth, on horseback, with tents, and all the comforts of opulent merchants; but if this be not possible, also in more humble characters. Each gang has its *Jemadar*, or leader; its *Guru*, or teacher; its *Sothas*, or entrappers; its *Bhuttotes*, or stranglers; and its *Lughaees*, or grave-diggers. On arriving at towns or villages, they pretend to meet by accident, and to have no previous acquaintance with one another. Some of the gang are then employed as emissaries to collect information; and when learning that any persons of property are about to undertake a journey, they endeavour to insinuate themselves into their confidence, and usually propose to them, under the plea of safety, or for the sake of society, to travel in their company; or else, they follow them, waiting for the proper opportunity of carrying out their murderous work. The latter is generally perpetrated by throwing round the neck of the victim a rope or cloth, which one of the gang holds at one end, while the other end is seized by an accomplice; and while the two Thugs draw the noose tight, and press the head of their victim forwards, a third seizes him by the leg, thus causing him to fall to the ground. The fatal injury is then easily inflicted. Travellers staying in the same choultry, or public resting-place, are sometimes murdered in the night. In attacking a traveller on horseback, generally one of the gang goes in front of the horse, while another keeps himself in the rear; a third, walking by his side, when finding him off his guard, suddenly seizes him by the arm, and drags him to the ground; the sufferer is then strangled in the usual manner. Three Thugs are therefore generally required to murder one man; two, at the least, are thought necessary—for to strangle a man single-handed is a rare occurrence, and a feat of this kind is esteemed by the fraternity a most honourable distinction, which goes far to ennoble, in the eyes of his fellows, the Thug who has accomplished it, and even his family, for many generations. After the murder is perpetrated, the body of the victim is generally mutilated, in order, it seems, to expedite its decomposition, and thus to guard against discovery. For the same reason, care is taken to inter the body at a spot where it is not likely to be found; and thus it could happen that entire parties of travellers were destroyed, and not a vestige of them was discoverable. The indiscriminate slaughter in which the Thugs seem to indulge, is to a certain extent restrained by superstition; thus, it is deemed unlucky to kill certain classes and castes; and, as a rule, the female sex is exempt altogether.

The mode of dividing the plunder is probably various. According to one account, 'a portion of it is usually appropriated to defraying the expenses of religious ceremonies; and sometimes a part was also allotted for the benefit of widows and families of deceased members of the gang. The residue of the booty being divided into several parts, was generally shared as follows: To the leader, two shares; to the men actually concerned in perpetrating the murder, and to the person who cut the dead body, each one share and a half; and to the remainder of the gang, each one share.'

The practice of Thugs is not restricted to adventures on land. The rivers of India also are infested by bands of these robbers, who have similar habits to those of the land Thugs. They generally go in considerable parties—the one assuming the dress of travellers of respectability, the others acting as boatmen. When going up the river, they always pretend to be men going on pilgrimage to Benares, Allahabad, or some other sacred place; when going down, they pretend to be on their way home from such places. The travellers intended for their victims are inveigled on the high-roads, and murdered inside the boat, while some of the gang above sing and play. At a signal given by these that all is clear, the bodies of the murdered men are thrown into the river.

The patron goddess of the Thugs is Devî or Kâlî, the wife of the god S'iva, and the deity of destruction. In her name they exercise their profession, and to her they ascribe its origin. Formerly, they believe, Kâlî co-operated with the Thugs, and assisted them in the disposing of the bodies of their victims by devouring them. But through an indiscretion of one of the fraternity, who, out of curiosity, pried into the proceedings of the goddess, she became displeased, and condemned them in future to bury their victims. But though she now refused her future assistance, she presented her worshippers with one of her teeth for a pickaxe, a rib for a knife, and the hem of her lower garment for a noose. Whether on the faith of this legend or otherwise, it is certain that the pickaxe is the instrument which, by all the Thugs, is held in the highest estimation. Its fabrication is superintended with the greatest care, and it is consecrated to its duties under many and minutely regulated ceremonies; and after it has thus been prepared, it is only intrusted to a Thug selected for this dignity on account of his shrewdness, caution, and sobriety. The place where, and the manner in which, it is

then deposited are likewise the subject of the strictest rules; and it is submitted to special purifications after each time that it has been used for the preparation of a grave. The pickaxe is, in short, looked upon with the highest reverence by a Thug; it is the symbol of his faith, and the chief object of his superstitions. That these superstitions are gross and numerous, may be easily anticipated. The belief in omens especially, plays a great part in a Thug's career. All his movements are regulated by it, and the learning of the Thugs consists in a thorough acquaintance with them.

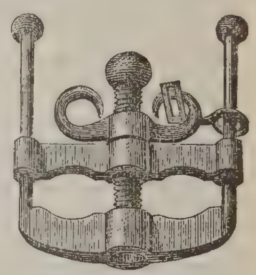
To a neglect of the warnings given by omens, or to an imperfect acquaintance with them, the Thugs invariably ascribe a failure of their undertakings, if it happens. When preparing for an expedition, the auspices are always solemnly taken; and only if favourable it is carried out. Among the bad omens, they count the meeting the corpse of any one belonging to the village, the meeting an oil-vendor, a carpenter, a potter, a dancing-master, a lame or blind man, a fakeer with a brown waistband, or a Hindu devotee with long traced hair. To sneeze is a bad thing at setting out on an expedition; to meet a woman with an empty pitcher, or an ass braying from the front, a pair of jackals crossing the road in front of the gang, to see a wolf cross the path from left to right. On the other hand, it is a lucky omen to meet a woman with a pitcher full of water, or a pregnant woman, or to hear an ass braying on the left while halting at a stage, or to see a single jackal passing from right to left, or an antelope from left to right. Superstitions like these—and it is not necessary to give more instances of them—sufficiently shew that the Thugs consider their murderous practices as countenanced and regulated by higher powers; and it is for the same reason that after every murder they perform a special solemnity called *Tapuni*. It is celebrated in honour of the terrific Kâlî, and its principal feature consists in addressing a prayer to the goddess, and in making the practical stranglers, those who formed part of the expedition, and committed the murders, partake of *gaur*, or consecrated sugar, the effect of which is believed to be irresistible. Other ceremonies are, of course, likewise performed on the occasion; but it is from the eating of the gaur that the strength and prosperity of the Thug are supposed necessarily to be derived. Another feast observed by the Thugs throughout India is called *Kurhae Karna* or *Kote*. It likewise takes place in honour of Kâlî, and the requisites for its celebration are goats, rice, ghee (butter), spices, and spirits. The superstitions of the Thugs are all of Hindu origin; but they are adopted also by the Mohammedans, who, while stout adherents to the tenets of the Koran, yet pay divine honours to the Hindu goddess of destruction. This inconsistency they sometimes reconcile by identifying Kâlî, whose other name is also Bhavânî, with Fatima, the daughter of Mohammed, and wife of Ali, and by saying that Fatima invented the use of the noose to strangle the great demon Rukutbeejdana.

At various periods, steps were taken by the native and English governments to suppress Thuggee—the practice of the Thugs—but it is only since 1831 that energetic measures were adopted by the British authorities to counteract the evil; and though it has not yet altogether disappeared, it may be safely assumed that it is fast dying out.—For a fuller account of the Thugs, the reader is referred to the *Illustrations of the History and Practices of the Thugs* (by E. Thornton, Lond. 1837)—whence the foregoing outline is taken; to the authentic reports of special cases contained in the same work; and to Meadow's *Confessions of a Thug* (Lond. 1840).

THU'JA. See ARBOR VITAE.

THU'LÉ, the name generally given by the ancients to the most northerly part of Europe known to them, and in the description of which fancy played a conspicuous part. According to Pliny, it was an island in the northern ocean, discovered by the navigator Pytheas, who reached it after six days' sail from the Orcades. The name T. appears to be merely a classic form of the Gothic *Tiel* or *Tiule*, 'remotest land' (comp. Gr. *telos*, a goal); and most modern geographers identify T. with Iceland. Some, however, prefer to seek for it in that part of Norway called *Thil* or *Thilemark*, or in Jutland, the extremity of which is known as *Thy* or *Thyland*. Ptolemy considers that Mainland, the principal member of the Shetland group, has the best claim to being regarded as the T. of Pytheas.

THU'MBIKINS, or THUMBSCREW, an instrument of torture for compressing the thumb, largely made use of by the Inquisition in Spain, and also occasionally used in England, when examination by torture was practised there. The last instance of its application in Britain was in the case of Principal Carstairs, on whom this mode of torture was inflicted for an hour and a half at Holyrood by the Scottish Privy Council, with the view of obtaining from him confession of the secrets of the Argyll and Monmouth parties, but without effect in producing any disclosures.



Thumbscrew.
(From an instrument in the Antiquarian Museum, Edinburgh.)

THUN, a picturesque and ancient town of Switzerland, in the canton of Bern, 17 miles south-south-east of the city of that name. It stands on the Aar, one mile from the Lake of Thun, out of which the river rushes past the town in a stream of crystal clearness. The old castle of the 12th c. with its corner towers, and the venerable church, are the chief buildings. T. is the starting-place for those who visit the Bernese Oberland, and is consequently visited by crowds every season. Pop. 3800.

THUN, LAKE OF, in the canton of Bern, Switzerland, between the town of Interlaken on the east, and that of Thun on the north-west; is 10 miles long, 2 miles broad, 1775 feet above sea-level, and in some places between 700 and 800 feet deep. The scenery is very attractive. Steamers ply on the lake, and there is a good post-road along the south shore.

THUNDER. See LIGHTNING.

THU'NDERBOLT, in Heraldry, a bearing borrowed from classical mythology, which may be described as a twisted bar in pale inflamed at each end, surmounting two jagged darts in saltire between two wings displayed with streams of fire.

Thunderbolt.

THU'RGAU (i. e., valley of the Thur), a frontier canton in the north-east of Switzerland, bounded on the N.-E. by the Lake of Constance, and on the W. and S. by the cantons of Zürich and St

Gall. Area, 384 sq. m.; pop. about 100,000. The surface, unlike that of the other cantons of the country, is undulating or hilly, but nowhere mountainous, the chief height being the Hörnli in the extreme south, 3605 feet. The principal river is the Thur, from which the canton derives its name, and which, flowing west-north-west through a broad valley, joins the Rhine in the canton of Zürich. The soil is fertile in the ordinary crops, and remarkably so in fruits—large tracts of open country being laid out in orchards, as well as vineyards. Three-fourths of the inhabitants are Protestants. Capital, Frauenfeld.

THU'RIFER (Lat. *thur*, incense, and *fer-*, to carry), the ministering attendant in the Roman Catholic Church, at solemn mass, vespers, and other solemn ceremonies, whose duty it is to carry the *thurible*, or incense-vessel, and either to minister incense (q. v.) himself, or to present the thurible to be used for that purpose by the officiating priest. The office of thurifer is one of those which belong to the so-called 'Minor Order' of *Acolyte*. See ORDERS. The thurible now in use consists of a metallic vessel for holding burning charcoal, commonly of silver or silver-plated, but occasionally also of gold, with a movable cap, and suspended from four chains, so as to be capable of being freely waved about in the air for the readier dispersion of the smoke of the incense which is thrown upon the live charcoal.

THU'RINGER-WALD (forest of Thuringia) is a considerable mountain-range of Central Germany, which extends from the junction of the rivers Werra and Horsel, near Eisenach (q. v.), in a south-east direction to the north of Bavaria, where it joins the Frankenwald, a ramification of the Fichtel-Gebirge. Its total length is about 50 miles, and its highest summits are Schneekopf (3400 feet), Gross-Beerberg (3435 feet), Inselberg (3222 feet), and Finsterberg (3209 feet). The range is composed mostly of granite, porphyry, and argillaceous schists, abounding in metallic veins, among which iron ore is most conspicuous, though many others are found more or less plentiful; and auriferous sands occur in some of the rivers which have their source here. The T. is parcelled out among the states of Weimar, Meiningen, Coburg-Gotha, Prussia, Schwartzburg, Reuss, and Hesse-Cassel.

THURI'NGIA (Ger. *Thuringen*), the name still borne by that part of Upper Saxony which is generally bounded by the Werra, the Saale, and the Harz Mountains, though it has no longer any distinct terminal significance. The country was so called from the people Thuringii (probably the descendants of the Hermunduri), who were found inhabiting it in the 5th c.

THURLES, a market-town and seat of a poor-law union, in the county of Tipperary, province of Munster, Ireland. It is a place of great antiquity, and is celebrated not only in the bardic history, but also as the scene of a great battle with the Danes. It is situated on the river Suir, 52° 42′ N. lat., 7° 47′ W. long., 86 miles south-west from Dublin, with which city, as well as with Cork, it is connected by the Great Southern and Western Railway. The population is about 4500, of whom nearly all are Roman Catholics. T. being the seat of the Roman Catholic archbishop, has two convents of nuns, a monastery of Christian Brothers, and a college for ecclesiastical and general education, numerously attended.

THURLOW, EDWARD, LORD, an English lawyer, was born, in 1732, at Little Bracon-Ash, in Norfolk. His father, a clergyman, sent him to school at Canterbury, where he obtained a sound knowledge of the Latin and Greek classics. Thence he proceeded to Cambridge, but in his zeal, it is said, to affect the character of an idle clever boy, he committed breaches of discipline which compelled him to leave the university. He became a student of the Inner Temple, and was called to the bar in 1754. He was a fellow-pupil, in a solicitor's office, with the poet Cowper, and still affected idleness, although, in reality, he worked hard to make himself a good lawyer. His lofty stature, strongly marked features, dark eyes bushy eyebrows, and look of self-possession and wisdom, led, it appears, every one with whom he came in contact to attribute to him qualifications he really did not possess. His gifts, however, were those which are most likely to insure early success at the bar. An accidental meeting, at a coffee-house, with the Scotch solicitors in the great Douglas case, led to his employment in it as junior counsel, and to his acquaintance with the members of the Douglas family. It was one of them, the Duchess of Queensberry, who, by her influence with Lord Bute, obtained for him, in 1761, the rank of King's Counsel. After this period, he acquired a still higher reputation by his speech in the Douglas case —the greatest effort of his life. In 1768, he was returned for Tamworth, and became a zealous supporter of Lord North. When, in 1771, he was appointed Solicitor-general, he attracted the special notice of George III. by the zeal he displayed in supporting the American policy of the government. In 1778, he was raised to the woolsack; and such was his influence with the king, that he was allowed, contrary to all precedent, to retain the office under the Rockingham administration. He caused great embarrassment by opposing all the measures brought in by that government. Under the coalition ministry, he was compelled to retire; but he was restored as Chancellor on Mr Pitt coming to power. For a time he supported the government; but relying again on the support of the king, he once more began to give trouble, and ventured to oppose the measures his colleagues brought forward. Pitt then intimated that he or T. must retire, and the king, without any hesitation, consented to his removal (1792). T. sank into comparative obscurity. He amused himself in reading the Latin and Greek classics with his nephews, and spent much of his time in visiting and receiving visits. He died at Brighton on September 12, 1826. Lord Campbell, in his excellent life of T., says he can find nothing recorded of him to justify the great reputation for ability he had among his contemporaries, and ascribes it chiefly to his assuming manner; but it must be recollected that he had no Boswell to record his talk, and that it was his conversation which was admired. Johnson would not have said of an ordinary person as he did of him: 'I would prepare myself for no man in England but Lord Thurlow. When I am to meet him, I should wish to know a day before.'

THU'RSDAY (Swed. *Thorsdag*, Ger. *Donnerstag*), the fifth day of the week, is so called from Donar or Thor (q. v.), who, as god of the air, had much in common with the Roman Jupiter, to whom the same day was dedicated (Lat. *Jovis dies*, Fr. *Jeudi*).

THU'RSO, a burgh of barony, seaport, and market-town on the north coast of Caithness, 20 miles north-west of Wick. It is irregularly built, but contains some handsome freestone houses, and two handsome churches. Thurso Castle, to the east of the town, is a fine venerable structure. The harbour is a safe one for vessels not over 150 tons burden. At Scrabster, on the west side of the bay, a steamer calls weekly, and there is a good roadstead with a pier. Ropes are manufactured; and cattle, grain, sheep, and paving-stones exported

The marine views from T. are exceedingly striking. Pop. about 4500.

THWARTS, in a boat, are the cross-benches on which the rowers sit.

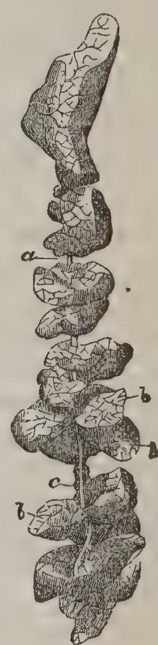
THY'LACINE (*Thylacinus*), a genus of carnivorous marsupial quadrupeds, nearly allied to opossums and dasyures. The muzzle is elongated, and somewhat dog-like. The tail is long and tapering. Only one species is known (*T. cynocephalus* or *Harrisii*), native of the mountainous parts of Van Diemen's Land, where it inhabits the wildest glens, but issues from them to prey on the sheep of the colonists, by whom it is commonly called the wolf, or tiger-wolf, and is destroyed by all possible means. Kangaroos, echidnæ, &c., seem to have been its ordinary prey before sheep were introduced. It is of the size of a large dog, and is the most powerful of Australian carnivorous quadrupeds. It is very active and fierce. It is not known to exist except in Van Diemen's Land.

THYME (*Thymus*), a genus of humble half-shrubby plants, of the natural order *Labiatæ*, having a two-lipped calyx, and four diverging stamens. GARDEN T. (*T. vulgaris*) is 6—10 inches high, with narrow almost linear leaves, and whitish or reddish flowers, which grow in separate whorls, six in a whorl. It is common upon dry hills in the south of Europe, and is very commonly cultivated in gardens, on account of its fragrance.—WILD T. (*T. Serpyllum*) has a procumbent stem with many branches, 2—3 feet long, oval leaves and purplish flowers, arranged in whorls, which are united in a head. It is abundant on hills and mountains in Britain, and in all parts of Europe, and the north of Asia. It is less fragrant than Garden T., but both species contain an aromatic essential oil. The flowering branches (*Herba Thymi* and *Herba Serpylli*) are used in medicine as a powerful stimulant, and those of Garden T. are also used in cookery for flavouring.—The LEMON T., or Lemon-scented T. of our gardens, is regarded as a variety of *T. Serpyllum*. It is generally of still lower growth than the common Garden Thyme.—No species of T. is indigenous in America.

THYMELEA'CEÆ, a natural order of exogenous plants, of which the Mezereon and Spurge Laurel (see DAPHNE) are familiar examples. This order consists chiefly of shrubs, with a few herbaceous plants, and contains about 300 species, natives chiefly of the warmer temperate countries. The leaves are undivided. The perianth is inferior, tubular, coloured, 4-cleft, or rarely 5-cleft, sometimes with scales in the orifice. The stamens are perigynous, often eight, sometimes four, and less frequently two. The ovary is one-celled, and the fruit one-seeded, either nut-like or a drupe. The bark is generally fibrous and tough. That of *Gnidia daphnoides* is used in Madagascar for ropes, and that of *Lagetta lintearia*, or Lace-bark, in the West Indies for whips. The bark of some species of *Daphne* and nearly allied genera is made into paper in the East. See DAPHNE. Poisonous properties prevail in the order. The bark is in general very caustic, and that of some species is used as a vesicatory, and for other medicinal purposes.

THY'MIC ASTHMA. See THYMUS GLAND.

THY'MUS GLAND, or simply the Thymus (Gr. *thymos*, sweet thyme, because the gland was compared to the flower of this plant by Galen), one of those structures which, like the spleen, supra-renal capsules, and thyroid gland, are placed amongst the ductless glands. It is a temporary organ, and is commonly stated to attain its greatest development in relation to the rest of the body during the latter part of fœtal life. 'But this,' says Dr Carpenter, 'is a mistake, for the greatest activity in the growth of this organ manifests itself in the human infant soon after birth, and it is then, too, that its functional energy seems the highest. This rapid state of growth, however, soon subsides into one of less activity, which merely serves to keep up its proportion to the rest of the body; but its increase is continued till the age of puberty is attained.'—*Principles of Human Physiology*, 6th ed., p. 143. After remaining stationary for some years, it gradually assumes, in well-nourished persons, the characters of a mass of fat. On examining the gland when its growth is most active, it is found to consist of two lateral lobes placed in contact along the middle line, extending from the lower border of the thyroid gland to the cartilage of the fourth rib, and covered by the sternum and by the margins of the muscles passing upwards from the top of that bone. The gland is of a pinkish gray colour, soft and lobulated on its surfaces; and by careful manipulation it may be shewn to consist of an assemblage of hollow glandular lobules, united together by connective tissue, all their cavities communicating with a central reservoir or main canal, from which there is no outlet. This arrangement is well seen in the accompanying diagram of a portion of the thymus gland of a calf. The thymus is about two inches in length, one and a half in breadth, and four lines thick, and at birth it weighs about half an ounce; its chemical constituents are water, albumen, gelatine, sugar (?), fats, leucine, sarkine, xanthine, and formic, acetic, succinic, and lactic acids, besides the ordinary inorganic salts—the number of the ingredients, many of them of rare occurrence elsewhere in the body, indicating that important chemical changes take place in their structure. Its exact uses are unknown, but like the other ductless or vascular glands, it doubtless plays some important part in the preparation and maintenance of the blood. The albuminous nature of the juice of this gland, and the finely granular appearance it presents, indicate that a material is here being prepared which is to be rendered subservient to nutrition; and various facts which have been noticed in regard to its changes of bulk (especially its rapid diminution in over-driven lambs, and its subsequent gradual redistention during rest, if plenty of food is given) strongly confirm these views.



Portion of Thymus of Calf, unfolded:

a, main canal; *b*, glandular lobules; *c*, isolated gland-granules seen in the main canal.

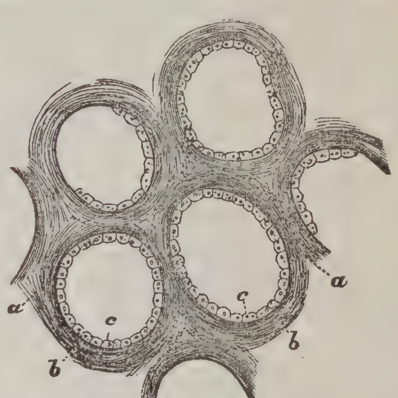
The anatomy, physiology, and development of this gland have occupied the attention of three of the most celebrated writers of the present century: see Sir Astley Cooper's beautiful monograph, *On the Anatomy of the Thymus Gland*, 1832; Mr Simon's

Physiological Essay on the Thymus Gland, 1843; and Professor Goodsir's Memoir 'On the Development of the Thymus Gland,' in the *Philosophical Transactions* for 1844.

The only disease of this structure requiring notice is hypertrophy—a condition which was supposed occasionally to induce suddenly fatal dyspnœa (breathlessness) in children. There are, however, sound reasons for believing that there is no essential connection between the glandular enlargement and the suffocative paroxysms; because (1) the affection termed *thymic asthma* may occur with an abnormally *small* thymus; and (2) when a thymus, enlarged by malignant disease (encephaloid, for example) does occasion dyspnœa, it is not sudden and paroxysmal, but constant in its nature. The disease is known under various other names, as *Laryngismus stridulus*, *spasmodic croup*, and *child-crowing*. This *bastard croup*, as Dr Watson calls it, is far more common than true croup, and is very liable to be confounded with it. 'In their most obvious symptoms, the two affections are much alike. The broad and essential difference between them is the absence in the spurious disorder of inflammation and of fever, and consequently of any concrete or other effusion from the mucous membrane of the air-passages. The child is seized all of a sudden, roused perhaps from its sleep, or checked in the act of sucking, by a catch, or interruption of its breathing, more or less complete. It strives and struggles to inspire, but is apparently unable to do so; at length, the effort is successful, and the breath is drawn in with a shrill whistling or crowing sound, like that which characterises the inspirations of croup or of hooping-cough, and depending, no doubt, upon the same cause—a narrowing (in this complaint, temporary) of the fissure of the glottis.'—*Lectures on the Principles and Practice of Physic*, 4th ed. vol. i. p. 866. The more complete the closure of the chink of the glottis is, the more intense will be the symptoms. In severe cases, the countenance becomes livid, the eyes fixed, and there is an entire suspension of the respiratory function for a while. The child makes vehement struggles to recover its breath, and at varied intervals, from a few seconds up to a minute or longer, air is admitted through the glottis, now partially open; and this rush of air produces the characteristic sound. A fit of coughing or crying then often supervenes, and the attack terminates with some exhaustion. If, however, the glottis does not partially open, the child will die suffocated (or in popular language, *in a fit*) at the end of two, or at most, three minutes, falling back pallid and exhausted in its nurse's arms. In association with these symptoms, is often a contracted state of the flexor muscles of the thumb, fingers, toes, wrist, and ankle, giving to the foot an appearance like that of club-foot. It has been observed by Dr Ley, who has written a volume on this disorder, and other observers, that there is a frequent connection between child-crowing and certain other affections, as (1) tumefaction of the glands in the neck and chest, and entanglement of the pneumogastric nerve or its branches among these glands; (2) painful dentition, which is apt to produce glandular swellings of the neck; and (3) excoriations behind the ears, and inflamed and irritable scalp, which also occasion enlargement of the glands. The nerves passing from the enlarged gland to the nervous centre convey the sensation of irritation; and the inferior laryngeal nerve, which supplies nearly all the muscles of the larynx, acts on the efferent or motor nerve, and excites spasmodic contraction of the muscles closing the aperture of the glottis. Hence the phenomena are those of Reflex Action.

During the paroxysm, the warm bath may be tried, if it can be got ready at once. The application of hot fomentations to the throat by means of a large sponge, is often very serviceable, and is usually more accessible than the bath. The muscles sometimes relax when cold water is freely sprinkled over the chest and face, and these simultaneous applications of hot and cold water are by no means incompatible. The subsequent general treatment must depend upon the exciting cause, on the painful dentition, the eruption of the head, &c. The state of the bowels and of the skin must always be carefully regulated, and change of air is always advisable. Phosphate of lime, in doses of from five to ten grains, three times a day, administered in chalk mixture, has been strongly recommended by Dr W. Budd in this disease, and is well deserving of a trial.

THY'ROID BODY or GLAND (Gr. *thyreos*, a shield, and *eidos*, like), one of the ductless or vascular glands, lying at the upper part of the trachea, and consisting of two lateral lobes, placed one on each side of this canal, and connected together by a narrow transverse portion at the lower third, called the isthmus. It is of a brownish red colour, and its normal weight is about an ounce, but it occasionally becomes enormously enlarged, constituting the disease called bronchocele or goitre. Each lobe is somewhat conical, and is about two inches long and three-quarters of an inch broad. The thyroid body differs from the other vascular glands in structure, for it 'consists of an aggregation of



Group of Gland-vesicles from the Thyroid Gland of a Child:
a, connective tissue; *b*, membrane of the vesicles; *c*, epithelial cells.

closed vesicles (*b*, *b* in the figure), which seem to be furnished with a true limitary membrane, and therefore to be real gland vesicles embedded in a stroma (*aa*) of connective tissue, and not communicating with any common reservoir. These bodies vary in diameter in the human subject from $\frac{1}{1000}$th to $\frac{1}{80}$th of an inch; and they contain an albuminoid plasma, which is either faintly granular or of a somewhat oily aspect, amidst which are seen a number of corpuscles, the greater part of them in the condition of nuclei, while some have advanced to that of cells.'—Carpenter's *Principles of Human Physiology*, 6th ed., p. 143. The thyroid body is abundantly supplied with blood by the superior and inferior thyroid arteries, which continue subdividing, till they ultimately form a very minute

capillary plexus upon the limitary membrane of the vesicles. This body, like the thymus and supra-renal capsules, is relatively larger in the fœtus and during infancy than in after-life.

From the investigations of Mr Simon (see his Memoir on the 'Comparative Anatomy of the Thyroid,' in the *Philosophical Transactions* for 1844), it appears that a thyroid is present in all mammals, birds, reptiles, and amphibians, and that he has discovered it in many fishes. Its presence in some of the fishes in which Mr Simon observed it, has, however, been called in question by Dr Handfield Jones (see his article 'Thyroid Gland' in the *Cyclopædia of Anatomy and Physiology*).

Mr Simon has propounded a theory regarding the function of this gland which is certainly ingenious, and probably correct. Basing his theory on the circumstance, that the thyroid arteries arise in close proximity to the cerebral, he considers that the thyroid gland acts as a diverticulum to the cerebral circulation, exercising at the same time its secreting function in an alternating manner with the brain.

Little need be said here regarding the diseases of this organ, as the most important of them, bronchocele or goitre, has been already described under the latter title.

THY'RSUS, in Botany, a Panicle (q. v.), in which the flower-stalks are short, and the flowers are thus close together, so that the panicle is dense. It is a very common form of inflorescence. The use of the term is, however, somewhat vague.

THYSANU'RA, an order of wingless insects of small size, and which undergo no metamorphoses. They are furnished with peculiar organs, either along their sides or at the extremity of the abdomen, which, as well as the legs, are used for locomotion. The whole order is comprised in two families—*Poduridæ*, or Spring-tails (see PODURA), and *Lepismidæ*. The *Lepismidæ* have an elongated body, covered with small shining silvery scales. The abdomen is furnished on each side with a series of movable appendages; it has also at its extremity a compressed appendage of two pieces, and three jointed bristles, which are used in leaping. The *Lepismidæ* inhabit dark and moist places, as behind window-shutters, beneath planks, &c.; many of them often in the interior of houses.

TI (*Cordyline Ti*, formerly *Dracæna terminalis*), a plant of the natural order *Liliaceæ*, and nearly allied to the Dragon Tree. See DRAGON'S BLOOD. It is found in the south-east of Asia, the Eastern Archipelago, the Sandwich Islands, and many other island groups of the Pacific Ocean. It attains a height of ten or twelve feet, sometimes more, with a tree-like form, lanceolate leaves of a reddish hue, and branching panicles. The fruit is a three-celled and three-seeded berry. The leaves afford food for cattle. They also form durable thatch for houses. Their fibres are sometimes made into cloth. It is most valuable, however, for its root, which is very large, and when raw, is hard, fibrous, and almost insipid; but becomes soft and sweet when baked—is very nutritious, and much used as an article of food. Good sugar is also made by evaporating its juice; the fermented juice is used as an intoxicating beverage, and a kind of ardent spirit is distilled from it.

Tiara.

TIA'RA, the triple crown of the pope, which is considered to be symbolical of his temporal, as the keys are of his spiritual authority. It is composed of a high cap of gold cloth, encircled by three coronets, with a mound and cross of gold on the top. From the cap hang two pendants, embroidered and fringed at the ends, and semée of crosses of gold. The original papal crown consisted of the cap alone, and was first used by Pope Damasus II., 1048 A. D. The cap was surrounded with a high coronet by Boniface VIII. in 1295; the second coronet was added in 1335 by Benedict XII.; and the third by John XXIII. in 1411.

TI'BER, the chief river of Central Italy, and the most famous in the peninsula, rises from two springs in a wood of beech trees in a dell of the Tuscan Apennines (province Arezzo), about six miles north of the village of Pieve-San-Stefana, and in lat. about 43° 45′ N. Its course until it reaches Perugia is south-south-east; thence, as far as Rome, it pursues, along an irregular zigzag line, a southern direction; but when it enters the plain of the Campagna, it curves to the south-south-west, and enters the Mediterranean by two branches, which enclose the Isola Sacra. The entire course of the river is about 212 miles. The most celebrated towns on or near its banks are Perugia, Todi, Orvieto, Rome, and Ostia; and its chief affluents are the Nera (anc. *Nar*), and Teverone or Aniene (anc. *Anio*) from the left, and the Chiana from the right. In the upper portion of its course, from its source to the city of Orvieto, it is rapid and turbid, and of difficult navigation. It is regularly navigable for boats of 50 tons to the confluence of the Nera, 100 miles from its mouth, and small steamers ascend to within 7 miles of that point. Wine, corn, charcoal, wood, and other produce from the interior are conveyed by the T. to Rome. Within the walls of Rome (q. v.), the width of the river is 300 feet, and the depth from 12 to 18 feet. Of its two mouths, the northern, the Fiumicino, is the channel of commerce; the southern, the Fiumara, is useless for commercial purposes, owing to the accumulation of sand at its mouth. The T. is supplied mostly by turbid mountain torrents, whence its liability to sudden overflowings of its banks; even the oldest Roman myth, that of Romulus, being inseparably associated with an inundation. Its waters, too, are still discoloured with yellow mud, as when Virgil described it—

Vorticibus rapidis et multa flavus arena.

TIBE'RIAS. See GALILEE.

TIBE'RIUS (TIBERIUS CLAUDIUS NERO CÆSAR), the second emperor of Rome, was the son of Tiberius Claudius Nero, one of the active partisans of Pompey and Antony in the war of the second triumvirate, and of Livia, a descendant of Appius Claudius Cæcus, and was born 16th November 42 B. C. The triumvir, Octavianus Cæsar (afterwards the Emperor Augustus) having become enamoured of Livia, the complaisant husband divorced her, and, though then pregnant with Drusus, she was immediately espoused by Octavianus (38 B. C.). T. being now one of the imperial household, received a careful education, was allowed by Augustus the same public honours as were paid to his nephew and grandsons, and as well as his brother Drusus, was employed in active service at the head of the legions on the outposts of the empire. T. was at this time in favour with the emperor and the Roman people, chiefly because his retired mode of life and subordinate position restrained his evil propensities; and his praises as a military leader were loudly sounded, though the character of his opponents was not such as called for the display of very great warlike ability. At the command of Augustus, he unwillingly divorced his wife, Vipsania Agrippina, to marry the emperor's daughter Julia (11 B.C.); but disgusted at her open profligacy, he gladly accepted a command on the

German frontier, and afterwards (6 B.C.) retired to Rhodes, where he lived for seven years, returning after Julia's banishment to Pandataria. The death of two of Augustus's three grandsons paved the way for the adoption of T., and of the third grandson, Agrippa Postumus, by the emperor, and for the appointment of T. as heir to the throne, Agrippa being, apart from his youth, wholly unfitted for the exercise of uncontrolled authority. Accordingly, T. ascended the throne (14 A.D.), and by his manly and graceful demeanour, prudence and moderation, gave promise of a happy reign. His mild and benignant sway at first, was doubtless due in part to the necessity of outbidding his popular nephew Germanicus (who was of Octavian blood by his mother's side) for public favour; but after his kinsman's death (19 A.D.), and the removal of all who were likely to put forth claims to the throne, T.'s true character became better known. He had always shewn himself reserved, jealous, timid, and irresolute, though not cowardly, and almost devoid of sympathy and affection; and with the sceptre firmly in his grasp, the development of these qualities produced the most suspicious and cruel of tyrants. During the life of his mother, however, T., who held her somewhat in dread, took little share in the government, but led a retired life, attempting to ape the virtues he had not. The chief events of this part of his reign were the increase in number and amount of the taxes, the removal of all power from the people and the senate, and the institution of prosecutions for *læsa majestas*, the latter being nothing else but a convenient mode of removing all who incurred the displeasure of the emperor. But after Livia's death (29 A.D.), he resigned the whole real authority into the hands of Ælius Sejanus, a Roman knight, and a commander of the prætorian guards, and gave himself up to the unrestrained indulgence of his sensual appetites. The empire did not suffer by the change, for Sejanus was a man of great ability and resolution, and well knew how to maintain his ascendency over the emperor by pouring into his suspicious ear tales of conspiracy, and then allaying the imperial fears, and satisfying his own private enmities by the condemnation for *læsa majestas* of eminent Roman citizens. In 27 A.D., T. retired to the island of Capri, there to wallow in his brutish enjoyments with more freedom, leaving Sejanus, whom he made his coadjutor in government, and equal in position, at the head of the government; and from this period till the discovery of the ambitious aspirations of Sejanus, and his downfall (31 A.D.), the Roman annals are crowded with proscriptions at Rome, and infamous excesses at Capri. Sejanus's successor, Macro, had all his vices, and few or none of his talents, and so the state of affairs was even worse than before, the senate exhibiting a rare degree of sycophancy, by endorsing with the most accommodating promptitude every order, however tyrannical, of the emperor or his confidant. It may seem strange that this frightful misgovernment by an aged debauchee and his ignoble favourite should have been so quietly submitted to by the Romans, but in reality their tyranny was confined exclusively to those of rank, the common people being treated with forbearance and occasional liberality, as there was nothing to fear from them. T.'s powerful constitution was at last completely destroyed by his excesses, and falling sick at Astura, he travelled to Misenum, where, in the villa of Lucullus, he ended his infamous life, 16th March 37 A.D., his death being hastened a few days either by poison or suffocation.

TIBE'T, THIBET, or TUBET, is the European name of a country in Central Asia, bounded on the N. by Mongolia, on the E. by China, on the S. by India, and on the W. by the N.-West provinces of Hindostan. The native name is Bod or Bodyul, the land of Bod. It covers an area of from 600,000 to 800,000 sq. miles, with the north-eastern part of which we are still very imperfectly acquainted. The pop. is estimated at 6,000,000.

Surface.—Although Tibet has been described by geographers as the loftiest inhabited table-land on the globe, its surface is traversed by mountain-chains. The average height of its western part is 12,000 feet, but it rises farther east to a level of 17,000 feet—the mean average elevation of the whole tract being not less than 15,000 feet—that of the top of Mont Blanc. From this enormous elevation, it looks down on the less elevated plateau of the Gobi Desert; and on the east, south, and west, it sinks to the low plains of China, India, and Turkestan. All round, it is fringed by mountains, which present on almost all sides abrupt slopes. From a mountain-knot at the western extremity of T., the great mountain-system of the Kuen-lun, which is the continuation of the Hindu Kush, runs east; and from the same point, the still greater chain of the Himalaya—the continuation of the Bolor Mountains—runs south-east. Between these mountain-walls (i.e., the Himalaya and the Kuen-lun) lies the Tibetan table-land, so called by geographers, although its surface is traversed by mountain-chains, which, at its western extremity, and as far east as the lake Manasarowar, interlace and ramify in a complicated manner. Although the Himalayas form the southern edge of the table-land, the greatest mountains of this range, 20 of which are higher than the loftiest of the Andes, stand out from the plateau, and are only connected with it by ridges of lesser elevation. They project from the high lands like buttresses which rise higher than the walls they support. In general, the descent from T. takes place by three gradations, the first of which is very abrupt. The mountain-roads by which T. is entered from India, pass through deep ravines cut by the streams in the mountains, and present the wildest and grandest scenes described by travellers.

The mountains which rise from the table-land divide T. into several natural regions. The Karakorum range, which runs parallel to the Himalaya, forms with them a great valley, drained on the west by the tributaries of the Indus, and on the east by the Sanpu. To the whole basin of the Indus, the name of Little Tibet is sometimes given; but more generally the upper basin is known as Ladak, or Middle Tibet; and the lower as Bultistan, or Lower Tibet. The countries drained by the Sanpu are described as Tibet Proper, which is in turn divided into Dsang, the district of the Upper Sanpu, and Wei, surrounding H'lassa, the district of the Lower Sanpu. Further east, the tract drained by the tributaries of the Yang-tze-kiang, in which are Lithang and Bathang, is known as Kham. North of the Karakorum range lies another region, a great elevated desert, called Khor on the west, and Katchi on the east; and at the north-eastern extremity of T. is a hilly tract, in which the Hoang-ho takes its rise, and in the centre of which is situated the Lake Ko-ko-nor. The provisional name given to the tract is the country of the Ko-ko-nor. The divisions of T., then, are—1. Bultistan; 2. Ladak; 3. Dsang; 4. Kham; 5. The desert of Khor and Katchi; 6. The hill-country of the Ko-ko-nor.

Geology.—The geology of T. is little known except on the south and western frontier. The highest part of the Himalaya consists of granites and crystalline strata, and in the neighbourhood of the Lake Manasarowar, of volcanic rocks. On the table-land, the strata belong to the most recent Tertiary epoch (the Pleistocene). They lie horizontally as they were deposited, and seem to have been lifted up in one unbroken cake to their present prodigious elevation.

They abound with the remains of the elephant and rhinoceros, from which it may be inferred that at a very recent period, one perhaps subsequent to that of man, the area now occupied by T. was a low land, with a tropical or semi-tropical climate. T. is believed to abound with silver, copper, and tin, but the absence of fuel renders its mineral wealth unavailable. Gold is found in considerable quantities; and salt, sulphur, borax, and nitre abound.

Climate.—T. lies between the latitudes of Naples and Cairo, and might be supposed to enjoy a similar climate. But its great elevation—greater, we have seen, than that of the highest of the Alps—renders it excessively cold during the winter, when its climate resembles that of the arctic regions, more than that of countries in the zone to which it belongs. The mountains and the great plains which lie between T. and the sea rob the winds of their moisture, and hence another peculiarity of the climate is its excessive dryness. Timber never rots, but it breaks from brittleness; flesh exposed to the wind does not become putrid, but dries, and can be reduced to a powder. The air loses its conducting power; and persons dressed in sheepskins give out long electric sparks when they approach conducting substances. During the winter, the winds are excessively high, and the weather-beaten rocks break into a dust, which mixes with the loose alluvial soil, and with it is blown about in blinding clouds. The limit of perpetual snow is from 16,000 to 18,000 feet high on the Tibetan side of the Himalaya, while on the Indian or southern side it is in some places only 13,000—a fact attributed to the dryness and purity of the air above the table-land. The Tibetan glaciers, particularly in the mountain region of the west, are of enormous extent. In a paper read to the Geographical Society (13th May 1866), Captain Montgomerie describes one of these, the Biafo Glacier, as 32 miles in length, or more than four times as long as the Mer de Glace. Further east, however, the mountains are less covered with snow, and no great glaciers have been described. Pastures and low bushes make their appearance at 18,544 feet—2800 feet higher than Mont Blanc, and 1279 feet above the snow-line on the Andes near Quito. Below this level, extends a country of bare and scanty pastures. Owing to the great dryness of the air, trees (the cedar and birch) are only met with in a few scattered spots on the hills. In the great plains, the pursuits of the inhabitants are chiefly those of the pastoral tribes of the steppes of Central Asia. In the valleys, however, the soil is more productive; and fruit-trees, the vine, and the European grains are cultivated. The conditions of the climate render irrigation necessary, and the construction and maintenance of terraces along the slopes. This has given rise to a kind of agriculture, characteristic of T., which demands skill and continuous labour, and which has called into existence an intelligent, strong, and hardy population. Among the productions of T. are barley, buckwheat, grapes, and all the European fruits. Wild animals are numerous in the Tibetan hill-countries, and among others met with may be enumerated the badger, the bear, the leopard, the lynx, the wild cat, and the tiger, wild oxen, the buffalo, the yak, and the musk-deer. All our domestic animals are known; and fish abound in the streams, but are prohibited as articles of food by the Buddhist religion.

Industry.—The Tibetans have made considerable progress in the industrial arts. They are ingenious jewellers, and manufacture extensively fabrics of wool and goats' hair, Buddhist idols, &c. In spite of the inaccessible nature of the country, and the absence of good roads and bridges, the rivers being crossed by inflated skins, a great trade is carried on with the neighbouring low lands. That with China is conducted chiefly at Sinning, but partly at H'lassa, by caravans, the goods being conveyed on the backs of oxen, mules, and horses. The raw produce of T. is exchanged for tea, or Chinese manufactures, and European cutlery. A great trade is also carried on with Nepaul and Bhotan, from which, in exchange for the produce of T., broadcloths and Indian manufactures are imported. From Turkestan the trade is no less important, the chief imports being horses and camels. The importance of the transit-trade of T., and the enterprise of the traders, may be judged of by the fact, that all the Chinese goods in Bhotan and Nepaul, where their use is general, are brought to these countries from T. over the passes of the Himalaya.

Language and Religion.—The language of the Tibetans, spoken also in Nepaul, and by the inhabitants of Bhotan, belongs to the monosyllabic or Chinese class. See PHILOLOGY. Tibetan is singularly free from dialects, from which it is concluded that it spread rapidly in recent times. It has a copious literature, chiefly religious. The religion of the Tibetans is a kind of Buddhism. See LAMAISM. At the extreme west, in Bultistan, however, Mohammedanism prevails, which, having spread from Cashmere and Persia, and not from Turkestan, is Shiite. Some practices common, it is believed, to the earlier races of men, are said to survive among the Tibetans. The most remarkable is Polyandry (q. v.), brothers being allowed to have one wife in common.

Government.—Almost the whole of T. is now tributary to China. The government is to some extent, however, in the hands of a Buddhist hierarchy, the name of the chief priest being the Dalai-lama, and the second the Bogdo-lama. These spiritual and temporal princes rule in different parts of the country. There are Chinese soldiers in all the chief towns, and a few years ago their number was said to be upwards of 60,000. The Chinese generals have the entire control of the army, and the direction of the most important temporal affairs. Commerce is in the hands of the government, and is closely watched, there being Chinese garrisons at the entrance to all the chief passes.

There are several important towns in Tibet, of which H'lassa (q. v.) is the chief.

History.—The early history of T. is legendary. The first king, who flourished 113 B.C., was exposed in a copper box, and afterwards found swimming in the Ganges. About the commencement of the Christian era, Sakya, the last great teacher of the Buddhists, is said to have settled at H'lassa, 'where he is supposed to be still alive in the person whom we call the Grand Lama.' In 821, T. was compelled to pay tribute to China. Early in the 10th c., King Dharma adopted Mohammedanism; but he was killed in 925, and Buddhism was re-established. In the beginning of the 11th c., T. was split into several states, and its power declined. In the 12th and 13th centuries, the Chinese began to conquer the eastern parts of T., which, however, did not become tributary to Pekin till 1720, when they were placed under their present government. Western Tibet has been more exposed to the inroads of the Turkish tribes than of the Chinese. The former were, however, expelled from it by Aurungzebe in the 17th c., and then it was that Mohammedanism was introduced. In the early part of this century, Western Tibet was annexed to the Sikh empire of Runjeet Singh. It now forms part of the territory under British supervision, known as 'Gholab Singh's dominion.'

Until a comparatively recent period, T. was only

known from the accounts given by Marco Polo and the Jesuit missionaries, travellers respectively of the 13th and 17th centuries. It was, however, visited in 1783 by Samuel Turner, who was sent by Warren Hastings on a mission to the Dalai-lama. It has since been partially explored by Moorcroft, Captain Strachey, the French Jesuits Huc and Gabet, the brothers Schlagintweit, to whose writings readers are referred for further information, and to Major Montgomerie's *Reports of Trans-Himalayan Explorations*, published in the *Journal of the Royal Geographical Society.* The latest information was received in 1873 from the Abbé Desgodins, a French missionary, who is making careful scientific observations.

TIBU'LLUS, ALBIUS, the Roman elegiac poet, was born of equestrian family, probably 54 B.C., and died young, not long after Virgil, about 18 B.C. We know nothing of his youth or education. From his equestrian ancestors he inherited an estate at Pedum, between Tibur and Præneste, which, like the estates of Virgil and Horace, had been either wholly or partially confiscated in the civil wars. T., however, recovered part of his property, and spent upon it the best part of his short life. He was patronised by Messala, whom, in 31, he accompanied into Aquitania, to suppress a serious revolt which had broken out in that province. He was present at the battle of Atax, which gave the final blow to the insurgents; and he celebrates, in a fine strain of poetry, the honourable part he bore in the campaign. Next year, Messala was sent to the East, and again T. accompanied him; but having been obliged from illness to stop at Corcyra, he returned to Rome. At this point, the public life of T. ceases; and henceforth he devoted himself to the study and composition of poetry. His Elegies, divided into four books, are mainly addressed to his mistresses, Delia, Nemesis, and Glycera, whose inconstancy or coldness he bewails in tender and exquisitely finished verses. The third book, however, is now believed to be the work, not of T., but of another and inferior poet; while the hexameter poem on Messala, with which the fourth book opens, is, from internal evidence, supposed to be also by another and inferior hand. Only the first book was published during the poet's lifetime, which, brief as it was, yet passed peacefully away amid all the blessings of pecuniary competence, patronage of the great, health, and fame. The character of T. was singularly pure, amiable, and winning. During life, he had the honour of being addressed in an ode and an epistle by Horace: after death, of being bewailed in an elegy of matchless beauty by Ovid. The best edition of his poems is that of Dissen (Göttingen, 1835).

TIC DOLOREUX. See NEURALGIA.

TICHVI'N, a town of Great Russia, in the government of Novgorod, 168 miles east-south-east of St Petersburg, on the Tichvinka, which, together with the canal of the same name, connects the Volga with the Baltic. It contains numerous churches, but is best known for its monastery, which contains a 'thaumaturgical' or miracle-working image of the Virgin. The inhabitants are chiefly employed in the transit-trade by land and water. Pop. 6387.

TICI'NO, the most southern canton of Switzerland, bounded on the W. and S. by Italy, and on the E. by Italy and the canton of Grisons. Area, 1082 sq. m.; pop. (1880) 130,777. Its surface, forming a portion of the southern slope of the Alps, comprises lofty mountains in the north. The northern boundary between T. and the cantons of Uri and Grisons is a range of the Lepontine Alps, rising in Mount St Gothard (q. v.) to the height of about 12,000 feet. Offsets from the Lepontine and Rhætian Alps occupy the greater part of the canton. In the south, the country falls away into flats, and the scenery becomes Italian in character. The principal rivers are the Ticino (q. v.), by which the whole of the canton, with the exception of a trifling portion, is drained, and from which it receives its name. In the north, cattle-breeding and the preparation of dairy produce are the chief employments. South of the Alpine regions are elevated forest-clad districts; and further south, oliveyards and vineyards, corn-fields and plantations of figs, almonds, oranges, citrons, and pomegranates occur. The canton varies as much in climate as in productions. Cattle, cheese, wine, fruits, and hay are exported. The northern part of Lake Maggiore, and almost the whole of Lake Lugano, are included within the canton. The inhabitants belong to the Italian type, and for the most part speak the Italian language, and are of the Catholic religion. The chief towns are Bellinzona, Locarno, and Lugano, each of which is by turns the seat of government.

TICINO, a river of Switzerland and the north of Italy, rises on the southern slopes of Mount St Gothard, and flows south through Lake Maggiore, and south-south-east through the north of Italy to its junction with the Po, four miles below Pavia. Entire length about 120 miles, for the last 75 of which, from the point at which it leaves Lake Maggiore, it is navigable.

TICK, the popular name of a great number of *Acarides* (see ACARUS), forming a section called *Suctoria*, having the mouth in the form of a sucker, with no apparent mandibles. They live by sucking the juices of plants and animals. Some of them are aquatic. The Harvest-bug (q. v.) is a well-known example of the suctorial *Acarides.* It belongs to a family called *Leptidæ.* The name T. is more particularly given to the family *Ixodidæ.* They abound in almost all parts of the world, but chiefly in warm countries, in which they are very troublesome pests. Many of them live in woods, attached to branches, but are ready to attach themselves to animals, which sometimes suffer greatly from their numbers, their blood-sucking powers, and the inflammation which they cause. The Tampan (q. v.) is a very troublesome T. of South Africa. The Carapata of Brazil is scarcely less

Harvest Bug
(*Leptus autumnalis*).

Dog Tick
(*Ixodes plumbeus*).

annoying. It infests dry bushy places, clusters of many hundreds being found clinging to very slender twigs, and they instantly transfer themselves to any horse, ox, or other quadruped which comes in contact with them, burying their serrated suckers in its skin, so that they cannot be withdrawn without considerable force. If not taken off, they go on increasing in size, till they become as large as a horse-bean, or even larger. Whole herds of cattle sometimes perish from the exhaustion which they cause. Wet weather, however, soon kills them, and an animal made to swim across a river, is almost freed from them at once. Travellers in

the interior of Brazil are sometimes obliged to pick hundreds off their own bodies before retiring to rest for the night.—The DOG T. (*Ixodes plumbeus*) is common in Britain, abounding on ferns in fir plantations, &c., in many places in autumn, and attaching itself to dogs, oxen, and other animals, sometimes even to man. It is in form and size like a grain of linseed, oval, shining, reddish, with a pale margin. The body swells to the size of a small horse-bean after the T. has attached itself to an animal, and the wound is attended with much inflammation and pain. Tortoises have ticks peculiar to them, which adhere to their neck, and by the thickness of their leathery coat, are preserved from being crushed when the head is retracted within the carapace.

TICKET OF LEAVE is a term which is properly applied only in regard to convicts in the Australian colonies. A kind of permit was given to them after a certain period of their sentences, if they could be trusted at large. It required the convict who held it to remain within a particular district. The term was afterwards popularly applied to the kind of document, called technically an 'order of licence,' which sets a convict at large in the British Empire before the expiry of his sentence. The occasion of its being first used was when, after the year 1840, the colonies, one after another, refused to receive convicts. If those sentenced to transportation were kept in prison in this country for the whole period of sentence, its severity would be greatly increased; and hence, by way of compensation to the convicts not taken abroad, part of their sentence was remitted. On the form of the sentence being recently changed from transportation to penal servitude, the partial remission was made systematic, as an inducement to good conduct and industry. Under the existing act of 1864, the period of remission which may thus be gained is for males about a fourth, and for females about a third, of the whole sentence. The method of adjusting the period is by debiting the convict with so many marks, representing the amount of industry that must be accomplished to gain the largest period of remission; and according to the proportion of these gained will the amount of remission or order of licence or ticket of leave be. See CONVICT, PRISON DISCIPLINE.

TICKING, a strong cloth, used chiefly for making beds, mattresses, and paillasses. Formerly, it was always manufactured of linen, but cotton is now largely used for this purpose. A very general character of ticking is that it is woven in stripes of two colours, blue and white.

TICKNOR, GEORGE, an American scholar and author, born in Boston, August 1, 1791, educated at Dartmouth College, admitted to the bar in 1813, but devoted himself to literature. From 1815, he spent five years in Europe, residing at Göttingen, Rome, Madrid, Paris, Edinburgh, and London, where he made the acquaintance of the most distinguished men of letters. Returning to America, he became Professor of French and Spanish Languages and Literature in Harvard University. In 1835, resigning his professorship, he went with his family to Europe, where he remained three years, collecting materials for his *History of Spanish Literature* (New York, 1849, 3 vols. 8vo; 3d ed., 1863), an exhaustive and admirable work, which has been translated into Spanish and German. Mr T. also edited *The Remains of Nathaniel Appleton Haven*, and wrote a *Life of Lafayette*, first published in 1825 in the *North American Review*. His last work (1864) was the biography of his friend W. H. Prescott. Mr T. died in 1871.

TICONDERO'GA, a small township in New York, U. S., on Lake Champlain, enclosing the outlet of Lake George, 95 miles north-by-east of Albany; and the name also of a lofty promontory in the township, of which the extremity, Mount Defiance, rises 750 feet above the lake. The falls of the outlet of Lake George, 150 feet in 1½ miles, afford constant water-power for timber-mills; and a vein of graphite supplies 30 tons of fine black-lead a year. The promontory was fortified by the French in 1755. In 1757, Montcalm assembled here a force of 9000 men, with which he took the English fort, William Henry, on Lake George. In 1758, General Abercrombie, with 15,000 men, attempted to storm the French fort, then called Carrillon, but was repulsed, with a loss of 2000. In 1759, it was invested by General Amherst, and the French dismantled and abandoned both this fort and Crown Point, which were then enlarged and strengthened by the English at a cost of £2,000,000. Being weakly garrisoned after the cession of Canada to Great Britain, it was, in 1775, surprised and captured by Ethan Allen. In 1777, it was recaptured by General Burgoyne, by erecting a battery on an unprotected height which commanded it; but after the surrender of Burgoyne, it was dismantled and abandoned. It was again occupied by the British troops in 1780, and at the close of the war, became a picturesque ruin.

TIDE-MILL. See WATER-POWER.

TIDES. It was known, at least as early as the time of Cæsar, though probably long before, that the time of high-water, and also the height of the tide, are in some way connected with the age of the moon. And even in the present state of science, what is called the *establishment* of a port, or the time of high-water at new or full moon (that is, the interval between the moon's crossing the meridian and the full tide), which is practically the most important part of the whole question, cannot be predicted by theory, but must be obtained by observation. The first attempt to explain the phenomena of the tides was made by Newton; and, considering the little that has, since his time, been effected, his approximate solution must be pronounced highly creditable, although in many respects unsatisfactory. D. Bernouilli and others have since slightly improved Newton's method; and a complete solution of the problem has been attempted by Laplace. The principles involved in this solution are undoubtedly correct, and the result, so far as it goes, leaves little to be desired. But it does not go far, for two reasons: we know very little as to the depth of the sea; and, even had we that knowledge, the excessive difficulties of the mathematical processes required in taking account of it, and of the forms of continents and islands, would be such as to render Laplace's method inapplicable.

Newton's approximate method consists in the study of the problem as a *statical* one, and this we will presently describe. Laplace, on the other hand, treats the problem as one of fluid *motion*. Airy and others have, more recently, attempted, with success, to simplify Laplace's process. Curiously enough, however, the results of all these theories are very much alike; and, while some of the results agree well with observation, others seem irreconcilable with it. We cannot explain Laplace's method without employing high analysis, quite unsuited to this work; so we must be content to describe the faulty theory. In the Newtonian or *Equilibrium* Theory, we consider the earth to be spherical, and covered with a layer of water, which would, of course, if left to itself, be uniformly deep over the whole surface. The

attraction of the moon (per unit of mass) on the water immediately below her, is greater than her attraction on the solid earth (per unit of mass), and tends, therefore, to raise the water at that part of the surface. At the point of the surface directly opposite to the moon, the water-layer is further from the moon than the bulk of the earth, and, consequently, the moon attracts the water (per unit of mass) *less* than it attracts the earth. The tendency is, as it were, to pull the earth away from the water, so that here also the water is raised, though not *quite* so much as on the other side, as the moon's attraction diminishes with distance. The effect of the moon's action on the previously uniform layer of water, is thus to elongate it both ways in the direction of the line joining the centres of the earth and moon. On account of the very small amount of this elongation, it is found by mathematical processes, which we cannot give here, that the form of the surface will become very nearly a prolate spheroid (a solid formed by the revolution of an ellipse about its *longer* axis).

[Before proceeding further with our explanation, it is necessary to say a few words with reference to a mistake often fallen into by those whose knowledge of mechanics is scanty; and at times paraded with a show of learning by a class of men who doubt such plain matters of fact as the moon's rotation, the oblateness of the earth, the inertia of matter, and what not. Such people say that, since, if the moon and earth were rigidly fixed to each other, the water would rise only on the side next the moon, this must be the case in nature also. This is the same mistake as those commit (see PERTURBATIONS) who allow that at new moon the sun virtually diminishes the moon's gravitation towards the earth, but refuse to allow that the same is true at full moon.]

We have next to consider that the moon revolves about the earth, and that the earth also revolves about its axis. Thus, the equilibrium figure has never time to form; but an imperfect form of it travels round the earth in the time of a lunar day (24 hours 54 minutes). If the moon be on the equator, it is obvious that similar portions of the water-spheroid will reach any one spot on the earth at intervals of half a lunar day (12 hours 27 minutes). If the moon's declination be considerable, such will not be the case—a place, for instance, whose latitude is equal to the moon's declination, will be reached by one pole of the wave-spheroid when the moon is on the meridian; but in 12 hours 27 minutes, the other pole of the spheroid will not pass over the place, but at a meridian distance of twice the latitude of the place, or twice the moon's declination. Thus, when the moon's declination is sensible, the two tides of each day are not generally equal in height, except for places on the earth's equator. This gives rise to what is called the *diurnal* tide, which is, as it were, superposed upon the ordinary, or *semidiurnal*, tide, and ought to be more sensible as the latitude is greater. Owing to fluid friction, and other causes, we should expect that the axis of the tidal spheroid would lag a little behind the moon, and this is found to be the case.

So far, we have a general explanation of the occurrence of tides twice a day, and of their dependence on the moon. But we started with two assumptions which are not consistent with fact, viz., that the earth is spherical and uniformly covered with water, and that the moon is the only tide-producing body. The corrections to be made in consequence of the inaccuracy of these assumptions, must now be explained. We commence with the latter. The sun, although at an immense distance compared with that of the moon, has such an enormous mass, that his tide-producing influence is comparable with that of the moon. In fact, it is easy to see that, as Newton shewed, the tide-producing power of an attracting mass is directly as the mass, and inversely as the *cube* of its distance. That it is directly as the mass, is obvious. To prove the other assertion, let R be the earth's radius, D the distance of the attracting body from the earth's centre, then the attraction per unit of mass on the earth is to that per unit of mass on the water nearest the attracting body as

$$\frac{1}{D^2} \text{ to } \frac{1}{(D-R)^2},$$

according to the law of gravitation. The difference between these quantities is proportional to the tide-producing force. But

$$\frac{1}{(D-R)^2} = \frac{1}{D^2\left(1-\frac{R}{D}\right)^2} = \frac{1}{D^2}\left(1+\frac{2R}{D}+\&c.\right)$$

$= \frac{1}{D^2} + \frac{2R}{D^3} +$, &c., the remaining terms being omitted, since D is always much greater than R. The difference is therefore approximately

$$\frac{2R}{D^3},$$

as stated above.

Now the mass of the sun is to that of the moon as 355,000 to 0·0125, and the sun's distance is about 400 times that of the moon. Hence the tide-producing power of the sun is to that of the moon as

$$355{,}000 \text{ to } \cdot 0125 \times 400^3$$
$$\text{or } 355 \text{ to } 800.$$

By calculations, which we cannot give here, it has been shewn that the difference of length of the axes of the wave-spheroid produced by the moon alone is about 58 inches; so that in that due to the sun it will be about 25·7 inches.

In consequence of the extremely small amount of these effects on the sea-level, we are entitled to simply add or superpose the separate effects of the sun and moon, in order to obtain their joint effect. And now we have at once the explanation of what are called *spring* and *neap* tides. At new and at full moon, the wave-spheroids due to the sun and moon have their axes almost coincident, so that we have a tide which is to the lunar alone as 800 + 355 to 800, or as 13 to 9 nearly; while, when the moon is in her first or last quarter, the axes are nearly at right angles, and the compound tide is to the lunar tide alone as 800 — 355 to 800, or as 5 to 9 nearly. Thus, the height of the spring-tide is to that of the neap-tide in the ratio of about 13 : 5.

Another curious phenomenon, which we can now easily account for, is the 'priming' and 'lagging' of the tides, or the *acceleration* and *retardation* of the time of high-water. If the tides were due to the sun or moon alone, they would recur at equal intervals of time; and, in fact, this is the case with the lunar and solar tides separately. But what we observe is the compound tide, and this will obviously have its maximum *between* two consecutive maxima of the lunar and solar tides; but nearer to the lunar tide, as it is the greater. Thus, if about new moon the sun passes the meridian *before* the moon, the tide is accelerated; if *after*, it is retarded. And the same is true about full moon, only that in this case our statement refers to passages of the sun and moon on opposite sides of the meridian. This retardation or acceleration has for its greatest value a period of rather less than an hour; and the respective maxima occur about 4½ days before and after the spring-tides.

But we meet with far more serious difficulties when we come to consider the actual distribution of water over the earth's surface; and it is here that future improvements must be looked for.

But even so inadequate an attempt at a solution as is the equilibrium theory, gives us the means of explaining a great many curious observed phenomena. It shews, for instance, how exceedingly small we should expect to find the tides in an inland sea, such as the Mediterranean; for there, even when the moon is most favourably situated, the utmost difference of level would be (by calculations which we cannot give here) only about an inch or two; and of this, part would be the rise in one portion of the sea, the rest the fall in others. The popular explanation of this phenomenon is very simple. We have but to notice that, according to the equilibrium theory, the form of the water is a spheroid of definite dimensions, its axes differing from each other by 58 inches. But a small portion of such a spheroid (of the dimensions of the Mediterranean, for instance) can hardly be distinguished from a sphere; so that the form of the surface of a limited mass of water will be but slightly altered by the attractions of the sun and moon.

It is obvious from what we have just said, that the rise of the water in tidal rivers, estuaries, and deep bays, where it sometimes amounts (even in calm weather) to more than 100 feet, cannot possibly be due to the moon's action upon the water of the mere river or bay, but must be almost entirely produced by the tidal wave in the ocean; and, in fact, this part of the problem presents comparatively little difficulty. Once grant the fact of the tidal disturbance of sea-level at the mouth of a river, and the calculation of the motion of the consequent wave in the river-channel is within the power of mathematics. It is by means of investigations made from this point of view, and by others concerning the effect of the moon on long canals, that Laplace's method has been improved. For the details of the process, see Airy on 'Tides and Waves,' in the *Encyc. Metrop.* All we can do here is to point out a few of the immediate consequences of the periodic rise and fall of the sea-level as regards the motion of the water of a tidal river. Here the tide always runs *up* the river, even when, as in the case of the Severn, this is the opposite direction to that in which the moon appears to move. In the open sea at the mouth of the river, the interval from high to low water is almost exactly equal to that from low to high water, each being about 6¼ hours nearly. But the further we go up the river, the greater becomes the disparity between these periods, high-water following low-water at shorter and shorter intervals, while the intervals during which the tide falls are correspondingly increased. In some cases, as at certain points in the Seine and Severn, the interval from low to high water is so short that the tide-wave rushes suddenly up, and, spreading over the flat sands at the side of the channel, forms a dangerous surf called a *Bore* (q. v.).

Connected with these peculiarities, there is also a singular effect produced on the direction of the current in a tidal river. In the open ocean, the water merely rises and falls, there being no perceptible tidal current. Sailors are in the habit of associating the cessation of currents, or 'slack' water, with the occurrence of high and low water. This is the case in bays, but not in rivers, and it gives rise to some curious errors regarding the time of high-water in rivers. Thus it is sometimes said that it is high-water in the centre of the Thames' channel long after it is high-water at the shore—an obvious absurdity. The truth is, the current does not cease simultaneously at the shore and in mid-channel. At the mouth of a tidal river, the water runs upwards for hours after high-water, and downwards after low; and the same is true, in a less degree, at places higher up the stream.

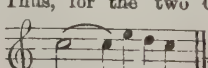
When considerable alterations of breadth or depth occur in the channel of a river, we find corresponding alterations in the amount of rise of the tide. Thus, according to Airy, at the entrance of the Bristol Channel, the whole rise at spring-tides is about 18 feet; at Swansea, 30 feet; and at Chepstow, 50 feet. At Annapolis, in the Bay of Fundy, the tide is said to rise 120 feet. Again, the same port may be reached by two tide-waves coming from the ocean by different channels; and here we have to compound the two disturbances just as we did with the separate lunar and solar tides. In the German Ocean, we have a very good example; but the most remarkable is the tide at Batsham, in Tonquin. At this port, two tide-waves meet, coming respectively from the Indian and China seas; these bring, simultaneously, opposite but nearly equal changes in the water level, and the effect is, that there is almost no perceptible tide.

Whewell, Lubbock, and others have lately added much to our knowledge of the *facts* of the tides; and have constructed what are believed to be tolerably accurate charts of *Cotidal Lines*—that is, lines representing the positions of the crest of the tide-wave at hourly intervals as it sweeps round the earth. A great deal, however, remains to be done in this direction, before we can hope to elicit from observation such hints as may enable us to improve the mathematical theory of the subject.

The frictional resistance to the motion of the tide-wave of course produces heat. This heat is a transformation of part of the earth's energy (see FORCE) of rotation; and thus it appears that the tides are gradually lengthening the day. We may see easily that this would go on, were the moon the only tide-producing body, so long as the earth rotates about her axis in less time than a lunar month. For, if the length of the (sidereal) day were that of a lunar month, the earth would always turn the same face to the moon; and the tide-spheroid would have a *fixed* position on the earth, and there would be no loss of energy by friction. Simple as this deduction is, though it seems to have been roughly guessed at by Kant, it was not formally enunciated till about a quarter of a century ago. Mayer was the first to publish anything on the subject, but it seems to have been previously noticed by others. One of the most curious deductions from it is the recent speculation which assigns, as the cause of the moon's turning always the same face to the earth, the friction of the enormous tides which must have been produced by the earth in her mass when it was in a molten state, on the surface at least, if not throughout.

The only work with which we are acquainted from which complete information as to our present knowledge of the subject of Tides may be obtained is that of Airy, in the *Encyclopædia Metropolitana*, already referred to.

TIE, in Music, an arch drawn over two notes on the same degree, uniting them so that they are played or sung as one single note of the same value. Thus, for the two C's written in the example



one is played of the value of a minim and quaver combined. The tie is often used in syncopated passages to connect the last note of one measure with the first of the succeeding

one, when the former note, which would otherwise be unaccented, acquires the emphasis of the latter:

See SYNCOPATION.

TIE-BEAM. See ROOF.

TIECK, LUDWIG, a brilliant and prolific German novelist and poet, was born at Berlin 31st May 1773, and studied at the universities of Halle, Göttingen, and Erlangen. He made his first appearance as an author in the *Straussfeder* (Ostrich-feather) Magazine, conducted by Musäus (q. v.) and J. G. Müller, for which he wrote a series of little tales, of which the best was *Die beiden merkwürdigsten Tage aus Siegmann's Leben* (The Two most Remarkable Days in Siegmann's Life). But the originality of his genius first displayed itself in his romances of *Abdallah* (Berl. 1795) and *William Lovell* (3 vols., Berl. 1795). These were followed by his *Peter Lebrecht, eine Geschichte ohne Abenteuerlichkeiten* (Peter Lebrecht, a History without Adventures, 2 vols., Berl. 1795—1796), and *Peter Lebrecht's Volksmärchen* (3 vols., Berl. 1797), which were equally remarkable for richness of fancy, artless simplicity, and an overflowing humour. In some of these *Märchen*, as, for example, his 'Bluebeard,' 'Puss-in-Boots' (*Der gestiefelte Kater*), and 'The Life and Death of Little Red Riding-hood' (*Leben und Tod des kleinen Röthkappchen*), he combated with satiric humour, perhaps, too, with somewhat of youthful arrogance, the 'enlightened' notions on which the literature of the 18th c. prided itself—shewing very distinctly his strong tendencies towards the deeper poetic spirit of the middle ages. The same polemic was maintained in his comedy, *Die verkehrte Welt* (The Topsy-turvy World, 1799). To this period also belong his *Herzensergiessungen eines kunstliebenden Klosterbruders* (Heart-effusions of an art-loving Monk, Berl. 1799), *Franz Sternbald's Wanderungen*, an art-novel (2 vols., Berl. 1798), and *Phantasien über die Kunst* (Fancies on Art, Hamb. 1799), all of which are full of a noble enthusiasm for art, but pervaded at the same time by a dreamy mystical religiosity, which is no longer admirable. These works brought T. into close relationship with A. W. von Schlegel and others, and led to the establishment of the literary sect or coterie known as the 'Romantic School,' whose influence on the later literature of Germany and France has been very great and not always very good. T. now married the daughter of a Hamburg clergyman who had been a friend of Lessing; and in 1799 went to Jena, where he added Steffens to the list of his friends. Here he published his famous *Romantische Dichtungen* (2 vols., 1799—1800). His translation of *Don Quixote* (4 vols., Berl. 1799—1801, 3d ed. 1831) far surpassed all previous attempts. In 1802, he joined A. W. von Schlegel in the *Musen-Almanach;* and in 1804 published his longest romance, *Kaiser Octavianus*. T.'s health now began to fail him, and in 1805 he visited Italy. On his return to Germany, he settled, after some changes, at Ziebingen in 1811, where he formed a friendship with the philosopher Solger, who exercised a great influence over his mind. Henceforth, we find less of the dreamy and formless mysticism of his earlier years, and more of the artistic element. The change becomes visible in his *Phantasus* (3 vols., Berl. 1812—1815), and in his *Ulrich's von Lichtenstein Frauendienst* (Tüb. 1815). In 1817, along with a friend, Burgsdorf, he paid a visit to England, where he collected fresh materials for his Shakspeare. From 1819 to 1840, he resided at Dresden; but on the accession to the throne of Friedrich Wilhelm IV. of Prussia, he was invited to Berlin, whither he proceeded, and where he resided for the rest of his life. His death occurred 28th April 1853. Other important works of T.'s, besides those already mentioned, are his *Novellenkranz* (Berl. 1831—1835; complete in 12 vols., Berl. 1853); in which there is hardly a trace of the credulous Romanticism of his earlier years, but abundance of lively and subtle talk on the literature and life of the Present; *Dramaturgische Blätter* (2 vols., Bresl. 1826), republished in his *Kritische Schriften* (4 vols., Leip. 1848—1852); *Shakspeare's Vorschule* (2 vols., Leip. 1823—1829); and his splendid continuation of Schlegel's translation of our great poet. T. revised a collected but incomplete edition of his works in 20 vols. (Berl. 1828—1842).—See Köpke's *Life of Tieck* (2 vols.).

TIEL, the seat of an arrondissement in the Netherlands, province of Gelderland, is picturesquely situated on the right bank of the Waal. In the 5th c., it was called Tellum or Thiela. The fortifications have been demolished, and formed into beautiful walks. Pop. 7748. Principal buildings are the Town-house, Court-house, Chamber of Trade, and the great Reformed Church of St Martin.

T. has a good haven, and large trade in agricultural produce and cattle. In 1864, 319 ships discharged grain, earthenware, wood, lime, coal, bricks, salt, &c.; taking in potatoes, grain, colza, pigs, flax, apples, cherries, &c. Principal industries are copper-founding, brick-making, tanning, book-printing, paper-making, beer-brewing, &c.

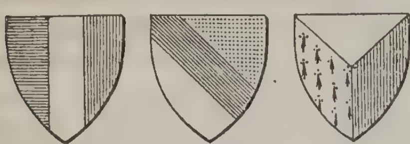
TIEN-TE (celestial virtue), the name given to the *Tae-ping-wang* (king of universal peace), the pretender to imperial authority in China, and the head of the mighty insurrection which for 16 years convulsed that country. See CHINESE EMPIRE and TAE-PINGS. The insurrection was under the direction of five chiefs, Hung-sew-tseuen, Hiang-tsew-tsing, Siao-tsha-kuei, Fung-hien-san, and Wei-tsing, independent of each other, but all acknowledging the supremacy of T.; and as, according to the plan of the rebellion, China, after being delivered from its Mantchu rulers, was to be divided among those chiefs, each of them assumed beforehand the title and insignia of 'king.' So little reliable were the statements which were forwarded to Europe respecting this insurrection, that for some time Hung-sew-tseuen, the chief among the five kings, and the military leader of the rebels, was confounded with their supreme head.

TIEN-TSIN, a large and important city and river-port of China, in the province of Chih-le, on the right bank of the Pei-ho, 34 miles from the mouth of that river by land, and 68 miles by the windings of the stream. It is the port of the city of Pekin, from which it is distant 80 miles south-east. The streets are unpaved, and the houses, principally built of mud or dried bricks, have a mean appearance, though the central parts of the town are filled with well-built houses. The maximum of heat in the summer is 106°, the maximum of cold is 6° below zero. The river is generally frozen over from about the 15th December to the 15th March, and the business at other times carried on by means of boats and junks, is taken up by sledges, which swarm on the river. By the Treaty of T., signed here November 1858, and by the subsequent Convention of Pekin, October 1860, the port was declared open; and a British consulate was established in January, 1861. In 1870, 258 vessels, of 100,223 tons, were engaged in the trade of T.; in 1871, the number of vessels was 316, of 124,517 tons. In 1867, the value of the imports was £4,500,000; that of the exports, £408,000; in 1868, the imports

amounted to £5,480,000; the exports to £314,920. In 1862, 9866 lbs. of cotton were exported. In 1864, 8,970,958 lbs. In 1871, the imports amounted to only £3,802,160; the exports to £630,441. The principal articles imported are gray and white shirtings, chintzes, and other cotton goods; needles, window-glass, sugar (brown and white), and paper; the chief exports are cotton, peas, and dates. Pop. reckoned at 1,000,000.—*Reports of Her Majesty's Secretaries of Embassy and Legation* (1862); and *Commercial Reports from Her Majesty's Consuls* (1866).

TIERCE. See FENCING.

TIERCE, TIERCÉ, in Heraldry, a term of blazon used to indicate that the field is divided by lines into three equal parts. A shield may be tiercé in pale, in fess, in bend, in bend sinister, or in pall; all which, with other arrangements in tierce, are common in French heraldry. Tierce in pale, in



IN PALE IN BEND IN PALL

English heraldry, is an occasional mode of marshalling three coats in one escutcheon under special circumstances.

TIE'RRA DEL FUE'GO (Land of Fire), an archipelago situated at the extreme south of South America, from the mainland of which it is separated by Magellan's Strait, consists of 11 large islands, of which the chief is King Charles's South Land, and about 20 islets; lat. 52°—56° S., long. 65°—75° W. The area of King Charles's South Land, which forms more than three-fourths of the entire area, is about 21,260 sq. m. This island, like the other islands of the archipelago and the coast of the mainland, is much broken on the west side by gulfs and inlets. The eastern coasts are, as a rule, level and wooded; while the western coasts are generally rocky and mountainous. The general aspect of the group is wild and desolate in the extreme. Some localities, however, are of quite a different character. The coast-scenery of Picton Island resembles that of the south-west coast of England. The south part of the island is chiefly in moor and down; the north part is covered with thick forests. The scenery is fine, and there are fine freshwater lakes, frequented by abundance of waterfowl. Many of the mountains are volcanic—from which circumstance this region has derived its name —and lava and volcanic productions are seen everywhere. The highest mountains rise to from 6000 to 7000 feet, and are covered with snow. The climate is raw and cold, violent rains and snowstorms occurring in every season of the year. In this region, the waters of the Atlantic and Pacific meet and struggle together, and terrific tempests are frequent. The flora of the region comprises some plants found in Great Britain. Wild celery and spoonwort are the only edible plants; but by far the most important articles of food are shell-fish, which abound on the coasts, and a globular fungus, which grows in clusters round the trunk of the antarctic beech—an elegant evergreen, and the prevailing tree in the archipelago. The inhabitants, the number of whom is estimated at 2000, are generally described as a short, ugly, beardless race with long black hair, of a rusty iron colour, and occupying the lowest rank in the scale of civilisation. Captain W. Parker Snow, who visited T. del F. in 1855, reports somewhat differently of the inhabitants. According to him, the natives are robust-looking, powerful, and of the middle height, being on an average over 5 feet 3 inches in height. The only quadruped among them is the dog. When driven to extremities, they first eat their dogs, and then kill and eat the old women of their tribe. More than one attempt has been made to convert these savages to Christianity, but hitherto such attempts have proved abortive. In 1850, a mission-party of seven men, under Captain Allen Gardiner, the projector of the expedition, arrived at Tierra del Fuego. The missionaries were not well received by the natives, and the narrative of their residence on these coasts is simply a record of miserable disasters. Owing to the grossest mismanagement on the part of the home authorities, the wants of the mission-party were neglected, and they found themselves in a short time destitute of provisions. The relief that had been promised never came; and in the autumn of 1851, the whole party, after undergoing horrible sufferings, died of starvation. In the autumn of 1854, another missionary expedition set sail from Bristol for T. del F., under command of Captain W. Parker Snow; but after many endeavours, the attempt to form a mission-station on T. del F. was abandoned.

TIERS ÉTAT (Fr. third estate), the third branch of the French estates, which consisted of representatives of the trading inhabitants of the towns, and of the peasantry in the country. The *tiers état* played an important part in the opening scene of the Revolution. On the two other estates of nobles and clergy refusing to join them and deliberate in a common chamber, they, on June 17, 1789, assumed the title of *Assemblée Nationale*, and the sole right to legislate for France. The French *tiers état* differed completely in its origin from the third estate or Commons of England. The latter originated in the permission granted to the minor barons, instead of personally attending the national council, to appear by representatives; and with the representatives of the minor barons were joined in one house the representatives of the municipalities, which, as corporations, came to be considered in the light of tenants *in capite* of the crown. The designation 'Commons,' and the absence of title, have often misled foreigners to suppose that the men who gained their liberties and constitution for the English people were the *roturiers* or *bourgeois*; whereas they mostly belonged to the class which would, in continental phraseology, be called the nobility of the country.

TIETJENS, or TITIENS, TERESA, one of the first living operatic singers. She was born at Hamburg, of Hungarian parents, in 1834, and made her *début* in that city in the character of Lucrezia Borgia in 1849, taking at once a very high position on the lyric stage; and at Frankfurt and Vienna she was even more warmly received. Her first appearance in London, in 1858, was quite a triumph; and her later career has quite justified all the expectations formed of her. Her voice is a soprano of great volume and purity, which the wear of six operas in the week seems powerless to injure. Few, if any, singers of German training have ever been so thoroughly at home in the richly-embellished Italian style. [Died Oct. 3, 1877.]

TIFFANY, a kind of very thin silk gauze.

TI'FLIS, a government of Russia, in the Caucasus, bounded on the N. by the Caucasus Mountains, and on the S. by Persia and the Turkish dominions beyond Mt. Ararat. Area, 18,296 sq. m.; pop. (1871) 499,261, chiefly Georgians, Armenians, and Tartars. It is traversed in several directions by chains of

mountains, which belong either to the Caucasian Mountains (the peak of Kazbeck, 17,500 feet high), and extend over the north and east parts of the government, or to the Ararat, Achaltzick, and Alagiz Mountains, spreading from the sources of the Kur and Arax over the south districts. The principal lake, that of Goktcha, is about 50 miles long, and nearly 20 miles in extreme breadth. The rivers, the chief of which are the Kur and Arax, rise amid mountains, are very rapid, are confined between high banks, and are not navigable. The climate varies with the varieties of elevation of the surface; the soil, very fertile in some tracts, is not in general cultivated. Grain, tobacco, cotton, indigo, vegetables, and grapes are produced abundantly. T. is rich in mineral springs and in timber, the principal trees being the oak, elm, chestnut, and maple. The Christian and Mohammedan are the predominant creeds.

TIFLIS, an important Russian city, capital of the government of the same name and of the territory of the Caucasus (and south of the mountain range of that name), stands on both banks of the Kur, 165 miles—direct line—east-south-east of the Black Sea. There are several manufactories, in which woollen and linen cloths, carpets, and arms are made. T. was formerly a fortress, and the capital of the district of Georgia. It carries on an active trade with Persia, and is the great emporium of the Russian territory south of the Caucasus. In the vicinity are naphtha springs as well as thermal springs, which are much visited. T. was founded in the 4th c., and annexed to Russia in 1802. Pop. 71,000, mostly Arminians.

TIGER (*Felis tigris*), one of the largest of the *Felidæ*, equal perhaps to the lion in size and strength, and superior in activity. It has no trace of mane.

Head of Bengal Tiger.

It is more slender than the lion, its whole form more cat-like, its head smaller and rounder. All its motions are performed with the utmost grace and apparent ease. It does not climb trees, but winds its way through brushwood or jungle with great dexterity, runs very swiftly, and can leap 15 or 20 feet. It takes its prey either by running, or, more frequently, by lying in ambush and leaping upon it. Its strength is such that it is capable of carrying off an ox or buffalo. It is sometimes 15 feet in entire length to the tip of the tail; an instance is on record of 18 feet; the height is from 3 to 4 feet. The tigers of some regions differ considerably in size from those of others; thus the T. of Bengal is much larger than that of Bokhara. The hair is thick, fine, and shining; in the colder countries which the T. inhabits, it is thicker and longer than in tropical regions. The colour is a bright tawny yellow, beautifully marked with dark transverse bands, passing into pure white on the under parts; the dark bands are continued as rings on the tail. The tail is long, slightly tapering, clothed with hair similar to that of the body. Individuals sometimes occur, of a pale whitish colour, obscurely striped, the stripes only visible in particular lights. The T. is found only in Asia. It abounds in Hindustan, in the Eastern Peninsula, in Java, Sumatra, and other tropical islands. It is found also in China and Japan, and in Persia. Its range, however, does not extend much to the west of a line drawn from the mouth

Bengal Tiger (*Felis tigris*).

of the Indus to the Caspian Sea. It is found as far north as the south of Siberia, and even on the banks of the Obi. It inhabits woods, and cannot exist without free access to water. The islands of the delta of the Ganges have long been celebrated as a haunt of tigers. The T. generally lies concealed in a thicket during the day, and seeks its prey by night. The prey is very often obtained by watching near the places to which animals resort for the purpose of drinking. Tigers prowl about villages, and enter cattle-folds; they also follow travelling-parties, and seize the yoke-oxen and buffaloes, particularly those which straggle away from the encampment at night. The ravages of tigers in some parts of the East Indies are very great; and a great number of human beings are destroyed by them. A notion prevails that a T. which has once tasted human flesh becomes eager for it, and prefers it to all other food; and a single T. has been known to kill and devour many people, watching near some frequented path, or prowling around a village. The truth appears to be that this is the mode of obtaining prey to which a T. sometimes resorts, when incapable, through old age, of the active exertion necessary for capturing buffaloes or deer. The T. brings forth three, four, or five young ones at a birth. When taken young, it is easily tamed, and often shews much affection for those who treat it with kindness. Tame tigers are not unfrequently to be seen in India.

The T. was less familiarly known to the ancients than the large African *Felidæ*. It is, however, mentioned by Aristotle, and it is frequently mentioned by the Latin poets. Pliny tells us that the first T. seen at Rome was a tame one belonging to Augustus. Claudius exhibited four tigers at once.

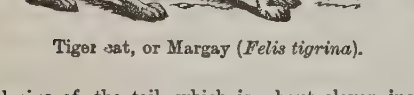
The T. frequently breeds in captivity, but not so frequently as the lion. A hybrid between the lion and T., the offspring of the male lion and the tigress, has been sometimes produced in menageries. It is striped like the T., and not maned. None of the hybrid cubs, however, have lived long.

Tiger-hunting is a favourite Indian sport, not unattended with danger, but all the more exciting on that account. Europeans generally ride on elephants when engaged in it, and the T. is shot from the back of the elephant. Natives, however, are employed to beat the wood or jungle for the

T., and lives are not unfrequently lost; but the destruction of a single T. is sometimes a thing of importance to a whole village or neighbourhood. The East India Company formerly gave a reward of ten rupees for every T. killed. In most parts of India, tigers are now much less numerous than they once were. Many expedients, of which the following are the chief, are adopted for their destruction in the countries infested by them. Bows with poisoned arrows are fixed in their paths, so as to be discharged on being touched. Heavy beams are also so placed as to fall upon the T. pressing against a rope, and crush it by their weight. Traps of various kinds are set, sometimes baited with a live goat or other small animal. The Chinese use a box-trap with a looking-glass placed in it, and the T., attracted by his own image, disengages the fastening of the lid, and is captured. This method is very ancient, and is represented in ancient sculpture. A very curious mode, practised in Oude, consists in scattering numbers of broad leaves smeared with a substance like bird-lime in the tiger's path, and if he sets foot on a smeared leaf, his fate may be regarded as sealed. He rubs his paw on his face, to get quit of the leaf, and the case becomes worse, the leaves are transferred to his face; fresh attempts to remove the nuisance only add more leaves, till he becomes completely blinded, and rolls on the ground for very rage; while the hunters, ambushed close by, apprised by his howlings, hasten to despatch him.

The T. is an emblem of power in the East. A tiger's head, gorgeously adorned with jewels, decorated the throne of Hyder Ali and Tippoo Sahib, and was among the spoils taken by the British at Seringapatam.

TIGER-CAT, a name often given to some of the *Felidæ* of middling size, which resemble the tiger in their form or markings. The Ocelots (q. v.) and the Serval (q. v.) sometimes receive this name, which, however, is not of very definite signification. The CHATI (*Felis mitis*) is a tiger-cat of South America, rather more than two feet in length,



Tiger cat, or Margay (*Felis tigrina*).

exclusive of the tail, which is about eleven inches. The colour is yellowish, with irregular dark patches, those on the back forming four longitudinal rows; the markings, indeed, more leopard-like than tiger-like. The chati prowls by night, and often carries away poultry from their roosting-places. Almost all tropical and sub-tropical countries have their tiger-cats. Several species are found in the East Indies.

TIGER-FLOWER (*Tigridia pavonia*), a plant of the natural order *Iridaceæ*, the only known species of its genus, which is distinguished by the three outer segments of the perianth being larger, and by the filaments being united into a long cylinder. It is a native of Mexico, but hardy enough to endure the climate of Britain, and much cultivated in flower-gardens for the singularity and great beauty of its flowers, which are, however, very evanescent. The root is a scaly bulb.

TI'GRIS (Heb. *Hiddekel;* i.e., the 'Dekel,' equivalent to *Digla* or *Diglath*, probably a Semitic corruption of *Tigra*, Medo-Persic for an arrow; hence Gr. *Tigris*, the 'arrowy' stream), a large river of Asiatic Turkey, rises south of Lake Goljik, in the mountains of Kurdistan, within a few miles of the eastern bend of the Euphrates (q. v.), flows south-east to Diarbekir, after which it makes a sharp turn, and flows due east for 100 miles to Til. Here it receives from the north a considerable affluent, the Bitlis, and once more altering its course, runs in a south-easterly direction through desert wastes and unpeopled pastures, until it falls into the Persian Gulf, after a course estimated at 1150 miles. Its chief tributaries, beside the Bitlis, are the Great and Little Zab, and the Dyala, all from the left, the waste land between it and the Euphrates (ancient Mesopotamia) not furnishing a single stream. At Kurna it joins the Euphrates, 90 miles above the mouth of that river in the Persian Gulf, and henceforth the united rivers bear the name of Shat-el-Arab (see EUPHRATES). In the upper part of its course, the T. is a very swift stream, whence probably its name, and it brings down great quantities of mud. The principal places on its banks are Diarbekir, Mosul, and Bagdad, with the ruins of Nineveh, Seleucia, and Ctesiphon.

TI'LBURG, a flourishing trading and manufacturing town in the Netherlands, province of North Brabant, is 15 miles south-west from 'sHertogenbosch, and 14 east-south-east of Breda. Its pop. is about 30,000, having more than doubled within 50 years. This prosperity began with the late King William II., when Prince of Orange, and commander of the army, taking up his headquarters at T., during the long contest which ended in the independence of Belgium. Much heath has been converted into arable and pasture lands, and numerous brick-works and woollen-cloth factories have arisen. In 1847, there were 13 wool-spinning works with steam-power; they now number 32, and the workers have increased from 2900 to 5000. The workmen's houses have each a strip of land attached, for the growth of vegetables and potatoes. Weaving woollen cloth, spinning, finishing and dyeing woollen fabrics, making soap, salt, tiles, bricks, and beer, are the principal industries. The chief buildings are the new palace, the town-house, the barracks, and the cloth-hall. T. has a high school with a course of five years, a drawing-school, and several charitable institutions. The people are nearly all Roman Catholics. The town is mentioned as early as 709.

TI'LBURY FORT, in Essex, is situated on the north bank of the Thames, opposite to Gravesend. Originally erected in the time of Henry VIII. as a block-house, it was converted (1667) into a regular fortification after the bold expedition of De Ruyter into the Thames and Medway. It is of a rectangular form, built chiefly of brick, with a massive stone portal, and is surrounded by a deep and wide fosse, which can easily be filled with water. Batteries of heavy ordnance are placed so as to command the river and the reach below; there are also piers for the landing of troops, stores, &c. The banks of the Thames being here very flat, the ground around the fort is during floods and high tides laid under water, and the atmosphere of the place is in consequence far from salubrious.

TILES (Lat. *tegula*, from *teg-*, to cover; Fr. *tuile*), plates of baked clay, of various shapes, according to their use, some being for roofs, some for pavements. The finer kinds of paving-tiles are known as Encaustic Tiles (q. v.). The small

cubical pieces of burnt clay, stone, glass, or other material used for mosaic pavements, are called tesseræ (Gr. *tessares*, four). See MOSAIC. Besides ornamental tiles, much improvement has been lately effected by various manufacturers in the different kinds used for roofing purposes, especially by the use of fire-clay, by which a tile is made not only greatly superior in strength and durability, but also in sharpness of form and diminution of thickness. Ridge-tiles of a very ornamental character are also largely made. Drain-tiles have been described under the head of PIPES.

TI'LESTONES, the uppermost group of the Silurian period, consisting of a reddish, thin-bedded, slightly micaceous sandstone, which in some places attains a thickness of 1000 feet. The beds were originally considered as of Old Red Sandstone age; then they were regarded as a transition group, forming a passage from the Silurian strata to the Old Red Sandstone; but it is now ascertained that the fossils agree in great part specifically, and in general character entirely, with those of the underlying Upper Ludlow Rocks, and they are accordingly considered to be the newest group of the Upper Silurian division. The Tilestones are well seen at Kington in Herefordshire, and at Downton Castle near Ludlow, where they are quarried for building purposes. From the latter locality, they have received the name of the Downton Sandstones.

TILIA'CEÆ, a natural order of exogenous plants, of which nearly 400 species are known, mostly trees and shrubs, with a few herbaceous plants. They are mostly natives of the tropics. A few are found in the temperate parts of the northern hemisphere. They have simple, alternate leaves, with stipules, and axillary flowers. The calyx is usually of four or five sepals; the corolla, of four or five petals. The corolla is sometimes wanting. The stamens are generally numerous, hypogynous, distinct; the outer ones sometimes abortive and petal-like. The ovary is composed of 2—10 carpels; there is one style, and the stigmas are equal in number to the carpels. As the characters somewhat correspond with those of *Malvaceæ*, so do the properties of the order, which are generally mucilaginous and wholesome, the bark fibrous. Some yield a light and useful timber, as the Lime (q. v.) or Linden tree, a well-known European representative of the order, the Halmalille (q. v.) of Ceylon, the *Grewia elastica* of India, and the *Luehia divaricata* of Brazil. The *bast* of the lime-tree is valuable from its fibrous character; that of the species of Grewia is used in the same way in India, and that of all the species of *Apeiba* in South America. The most important fibrous plants of the order, however, are the species of *Corchorus* (q. v.), which yield Jute (q. v.).

TILL, a term employed, chiefly in Scotland, for the Boulder-clay (q. v.). See also PLEISTOCENE.

TILLA'NDSIA. See BROMELIACEÆ.

TILLEMONT, SEBASTIAN LE NAIN DE, the well-known ecclesiastical historian, was born at Paris, November 30, 1637. His father was Jean le Nain, who held the office of *Maître des Requêtes*, the title, De Tillemont, by which the historian is commonly known, being derived from a small estate near Vincennes, which belonged to his family. He was educated at Port Royal, where he early imbibed those serious and rigorous views of the spiritual life which characterised the members of that celebrated society. His theological studies were marked from the first by a spirit of inquiry into the writings of the Fathers; and he is said to have begun as a student those analyses of the works of the Fathers, especially of the Apostolic Fathers, which form the staple of the early volumes of his History. Naturally of a timidly scrupulous disposition, he hesitated long about the choice of a profession; but after various changes of life, he at last received subdeacon's orders in 1672, being then 35. He deferred his ordination as deacon till the end of 1673; nor was it till 1676 that he was ordained a priest, mainly at the persuasion of his friend, Le Maistre de Sacy, who had long been his spiritual adviser, and with whose attachment to the Jansenistic principles he sympathised at least to a certain extent. In 1679, T. took up his residence at his family estate of Tillemont, where he resided till 1681. In that year, he made a visit to Holland and the Low Countries, for the purpose of visiting Arnauld and the other Jansenist refugees. He was induced, in the following year, to undertake a parochial charge—that of St Lambert; but he held it only for a short time.

During these years, he had steadily pursued the historical studies which he had commenced almost during his school-days; and he had now prepared the first portion of his long-projected work on the History of the Church. He was induced, on the very eve of printing, to change the plan of the work. In order to avoid the opposition of the censor, to whom, as a theological work, it would have been necessary to submit it in its first form, and whose suspicions were aroused by the known association of T. with the Jansenist party, T. separated from the Church History the History of the Emperors, which he was enabled to print as a distinct work, without referring it to the censorship, under the title *Histoire des Empereurs* (6 vols. 4to, 1690). The success of this work disarmed the opposition of the church authorities. The hostile censor was replaced by a less exacting one; and eventually, in 1693, the first volume of the Church History appeared under the title *Mémoires pour servir à l'Histoire Ecclésiastique des six Premiers Siècles* (16 vols. 4to). Neither of these works, however, was completed during the author's lifetime. Only four out of the six volumes of the *Emperors*, and four out of the sixteen of the *Histoire Ecclésiastique*, were printed under his own care. The remaining volumes were completed by him, but did not appear till after his death. The *Emperors* comprises all the reigns from Augustus to Anastasius (518); the *Histoire Ecclésiastique* comes down to about the same period. The plan of both is very much the same, being in great part a compilation of the original writers, as far as possible in their own words, but arranged with great skill and judgment, and linked together by such explanations and such a chain of narrative (within brackets) as is necessary to render them intelligible, and to carry on the course of events in a connected recital. Both these works have maintained, even to this day, their reputation for learning and impartiality; and even in the acrimonious contests of the 17th c., there was but little impeachment of T.'s orthodoxy, so far as the Histories are concerned. His other writings, left in manuscript, were for the most part used as materials by later compilers. Some of his letters have been appended to his *Life*, published by his friend Tronchet, canon of Laval (Cologne, 1711). T. died at Paris on the 10th January 1698, having just entered upon his 61st year. The extent and accuracy of his erudition are still freely acknowledged, and his authorities have supplied the materials of most of the church histories compiled since his time.

TILLER. See HELM.

TILLOTSON, JOHN, Archbishop of Canterbury was the son of a clothier, and was born at Sowerby, in Yorkshire, in 1630. His father, Mr Robert Tillotson, was a zealous Puritan—a circumstance

that is not a little curious, when we consider that the son ultimately turned out the most catholic churchman of his age. T. studied at Clare Hall, Cambridge, where he took the degree of B.A. in 1650, and of M.A. in 1654. The writings of Chillingworth are said to have exercised a powerful influence on his mind during his university curriculum; but he owed not less to his friendly intercourse with Cudworth, More, Rust, Smith, Wilkins, and other eminent scholars. In 1656, he became private tutor in the house of Edmund Prideaux of Ford Abbey, Devonshire, Attorney-general under the Protector, but appears to have returned to London shortly before Cromwell's death. At what time T. entered into orders, or who ordained him, is not known, but he was a preacher in 1661—attached apparently to the Presbyterian party in the Church of England, for at the famous Savoy Conference (q. v.) he was present on the Presbyterian side; but he submitted at once to the Act of Uniformity (1662); and in December of that year, was offered the church of St Mary Aldermanbury, London, of which Edmund Calamy had been deprived; but declined it. In 1663, he was appointed to the rectory of Keddington in Suffolk; but almost immediately after, was chosen preacher at Lincoln's Inn, where his mild, evangelical, but *un*doctrinal morality was at first little relished. 'Since Mr Tillotson came,' said the Benchers, 'Jesus Christ has not been preached among us.' However, as the graces of his character gradually displayed themselves, his popularity increased, especially when it was found, that although not a Puritan, he was nevertheless averse to atheism and popery. In 1664, he published a sermon *On the Wisdom of being Religious;* and in 1666, *The Rule of Faith*, in reply to a work by an English clergyman named Sargeant, who had gone over to the Church of Rome. About the same period, he took the degree of D.D.; and in 1670, was made a prebend of Canterbury. Two years later, he was promoted to a deanery; and in 1680, published a somewhat notable sermon entitled *The Protestant Religion vindicated from the Charge of Singularity and Novelty*, in which he advanced the proposition, untenable by a Protestant, that 'no man is at liberty to affront (i. e., to attack) the established religion of a nation, though it be false.' This proposition he subsequently, on reflection, abandoned. Along with Burnet, he attended Lord Russell during his imprisonment for complicity in the Rye-house Plot; and on the accession of William III., rose high into favour. In 1689, he was appointed Clerk of the Closet to the king; and in April 1691, was raised to the see of Canterbury, vacant by the deposition of Sancroft (q. v.), after vainly imploring William to spare him an honour which he foreboded would bring him no peace. Nor was he mistaken in his painful presentiment. The non-juring party pursued him with unrelenting rage to the end of his life; but their animosity could not extract one murmur of complaint, or one vindictive retaliation from the meek, humane, and tolerant primate. He did not long enjoy his dignity, dying of palsy, 18th November 1694, at the age of 65. A collected edition of his *Sermons* was published after his death by his chaplain, Dr Barker; and has been frequently reprinted. They were translated into German by Mosheim; and were long highly popular on account of their clear, solid, and refined thought, their easy eloquence, and their humane and moral piety. T.'s life was written by Dr T. Birch (Lond. 1752).

TILLY, John Tzerclas, Count of, one of the greatest captains of the 17th c., was born in 1559, at the château of Tilly in Brabant. A pupil of the Jesuits, his natural sternness of character inclined him to embrace their fanatical ideas; and this bent of mind was fixed by the examples of Alba (q. v.) and Requesens, under whom he was initiated into the art of war in the Low Countries. After a term of distinguished service in Hungary against the Turks, he was appointed (1609) by Duke Maximilian of Bavaria to reorganise his army, but resigned this post to take the command of the Catholic army at the outbreak of the Thirty Years' War (q. v.), and in conjunction with Duke Maximilian gained (8th November 1620) the battle of Prague, which dissipated the ambitious dreams of the Elector-palatine. During the course of this war, he separated, by able strategy, the armies of Mansfeld and of the Markgraf of Baden, beat the latter at Wimpfen, expelled Christian of Brunswick from the Palatinate (1622), defeating him at Höchst (22d July 1622) and at Stadion (August 1623); the latter conflict, which was of the most desperate character, lasting for three days. Created a count of the empire, he was next opposed to the king of Denmark, whom he conquered at Lutter (17th August 1626), and in conjunction with Wallenstein, compelled to sign the shameful treaty of Lübeck (1629). In the following year, he succeeded Wallenstein as commander-in-chief of the imperial forces, and took by storm the town of Magdeburg (10th May 1631). The unheard-of atrocities which he allowed the Croats and Walloons of his army to perpetrate on this occasion, have affixed to his otherwise high reputation a foul blot, ineffaceable by all the cosmetic arts of his numerous apologists. On the 14th May, he made a solemn entry into the ruined city, attended the celebration of a *Te Deum* in the cathedral, and then sent to the emperor a despatch in which occurs the remarkable passage: 'Since the capture of Troy, and the destruction of Jerusalem, a victory such as this has never been seen!' From this time, however, fortune deserted him; for his next opponent was the great Gustavus Adolphus, who completely routed him at Breitenfeld (17th September 1631); and though, in the following spring, he obtained some minor successes over the Swedish general Horn, the king speedily forced him to retreat behind the Lech in Bavaria, and (5th April) forced the passage of the river right in his front, after a desperate conflict, in which T. was mortally wounded. He was removed to Ingolstadt, where he died, 30th April 1632. T., the victor in 36 battles, was reckoned the best general of the time till his defeat by the Swedes; he was small in stature, and of a meagre habit of body, with a stern and energetic cast of countenance. Sober and continent, a despiser of luxury and wealth, his zealous support of the Catholic party was entirely founded upon fanatical zeal for the supremacy of a religion which he regarded with more than monkish devotion.

TIL-SEED. See Sesamum.

TI'LSIT, a town of Prussia, in the province of Prussia, on the left bank of the Memel or Niemen 65 miles north-east of Königsberg. Pop. 19,476. It stands in a fruitful district, called the Tilsit Flat, has broad streets, and a cleanly appearance. Its castle and town-hall are the chief buildings. It carries on an active transit-trade with Russia, besides considerable trade in timber, corn, butter, cheese, and Russian products, and has paper, sugar, and oil-mills. T. will be ever memorable in history for the treaties which were there signed between France and Russia on 7th July, and France and Prussia on 9th July, 1807. By the former of these Napoleon agreed to restore to the king of Prussia a great portion of his dominions, his Polish

acquisitions being joined to Saxony (see POLAND), and his possessions west of the Elbe formed into the nucleus of the new kingdom of Westphalia; Danzig was declared an independent city; the Prussian province of Bialystok was ceded to Russia; the dukes of Oldenburg and Mecklenburg, the czar's relatives, were reinstated by Napoleon, and in return, the Bonapartist kings of Naples and Holland were recognised by the czar; &c. By the latter, the king of Prussia recognised the kings of Holland, Naples, and Westphalia, and the Confederation of the Rhine, agreed to the cessions laid down in the Russian treaty, and to other minor alienations and concessions to Saxony, amounting in all to nearly one half of his dominions; to the exclusion from his harbours of the commerce of Great Britain, and to the occupation of the Prussian fortresses by the French, till the payment of an enormous ransom. The weighty importance of the alterations effected by this treaty is, however, dwarfed before the startling magnitude of the *secret provisions* signed between France and Russia. By these were arranged the resignation of the empire of the East to Russia, Roumelia and Constantinople being specially excepted by Napoleon, and the acquisition of the Spanish peninsula by France; the two powers were to make common cause against Great Britain, and were to force the three courts of Stockholm, Copenhagen, and Lisbon to join them; and Napoleon agreed to increase no further the power of the duchy of Warsaw, and to do nothing which might lead to the re-establishment of the Polish monarchy. By a further agreement, not put formally into writing, the mouths of the Cattaro, the Ionian Isles, Sicily, Malta, Egypt, and the papal dominions were to be taken by France; and Greece, Macedonia, Dalmatia, and the Adriatic coasts, on the partition of Turkey; while on the other hand, Russia was to obtain the rest of Turkey, and was allowed to seize Finland. These secret articles are given on most excellent authority, and their correctness is further vouched for by the conduct of France and Russia for the next few years.

TIMBER, a general term applied to all wood used for purposes of construction. Most of these have been described under their respective names; but the following tabular statement will shew the value of some of the leading sorts of colonial timber which are now beginning to be imported into Britain:

Name.	Colony whence imported.	Breaking Strain of Specimens two in. sq. by twelve in. long.	Specific Gravity.
		lbs.	
Iron-wood,	Jamaica	14,991·2	
Greenheart,	B. Guiana	12,215·6	1·089
Hickory,	N. S. Wales	7,795·4	
Mora,	B. Guiana	9,700·2	0·922
Water-gum,	N. S. Wales	7,760·1	
Blue-gum,	N. S. Wales	7,167·1	0·843
Bully Tree,	Jamaica	6,724·0	
Purple-heart,	B. Guiana	6,393·3	
Locust Tree,	B. Guiana	6,062·7	
Stringy-bark,	N. S. Wales	5,795·9	
Cedar,	Jamaica	3,196·7	
Yacca,	Jamaica	2,204·6	

The trade in timber is, of course, very extensive. Besides that grown in Great Britain, there is annually imported from the colonies and foreign countries an enormous quantity. Of fir, the imports in 1865 were 4,014,655 loads, of which rather more than one-half was from the North American colonies, and the remainder from foreign countries; of oak, 490,826 loads, of which 230,000 loads were from foreign countries; and of miscellaneous kinds, 2,706,480 loads—the load being 50 cubic feet; the total value of all of which was, in round numbers 12½ millions sterling.

TIMBER, in point of English Law, when growing on land, belongs to the owner of the land; or in case of a lease, to the landlord. In the case of a life-estate in the lands, the tenant for life, unless restrained by covenant or agreement, is entitled to estovers or botes; i. e., wood necessary to repair or burn in the house, and to repair hedges and fences. But the tenant for life cannot commit voluntary waste by felling trees. If the timber is in such an advanced state that it would be injured by standing longer, the Court of Chancery has power to grant leave to sell it, in which event the principal of the price will belong to the reversioner, and the interest thereof to the tenant for life. If, however, the estate for life is declared to be given without Impeachment of Waste (q. v.), as is often the case, then the tenant for life may cut timber to a certain extent with impunity. The tenant for life is entitled to all timber that is blown down on the estate. With regard to ordinary tenants or lessees of lands, though the timber is part of the inheritance, and belongs to the landlord, yet the tenant may cut down the underwood, and take sufficient estovers, or wood, to do repairs. Timber is also protected against third parties who steal or injure it. Thus, whoever steals, cuts, breaks, or damages trees with intent to steal them, provided the injury exceed one shilling in value, incurs a penalty of £5; and on repeating the offence, imprisonment may be added: so whoever unlawfully and maliciously cuts, breaks, barks, or otherwise destroys trees to the value of one shilling and upwards, forfeits £5, or may be imprisoned, in addition to, or as a substitute for such payment, with increased punishment for repeated offences of the same description.

TIMBERS of a ship are the upright ribs, based on the keel, and rising to the gunwale, on which the planking is fastened. See SHIP-BUILDING.

TIMBER TREES. Trees valuable for their timber are very numerous, and are found in all the warm and temperate parts of the world, except where the aridity of the soil, or the sea-breeze, prevents their growth. They belong to very many and widely different natural orders, all of which, however, are orders of Phanerogamous plants; the only Cryptogamous plants which assume the form of trees being the Tree Ferns (q. v.), none of which yield valuable timber. Of Endogenous plants, none have any claim to be mentioned among timber trees, except some of the Palms (q. v.); the only other endogens, indeed, which can be called trees being a very few of the *Liliaceæ*, as the Dragon Tree. See DRAGON'S BLOOD. Of Gymnogens, the *Coniferæ* are in general of some value for their timber, and some of them are amongst the most useful of all timber trees, as the different kinds of Fir and Pine. A far greater number of timber trees, however, are true exogens, as the Oak, Ash, Elm, Beech, Sycamore, &c., in the colder temperate zone; the Chestnut and Walnut among those of the warmer temperate; the Mahogany, Teak, &c., among those of tropical countries. It is impossible, within our space, to attempt an enumeration. Notice is taken of the most valuable timber trees of different countries in the articles on these countries; of those belonging to particular natural orders, in the articles on these orders; and the most valuable kinds are noticed in separate articles. For the cultivation of timber trees, see the article ARBORICULTURE. Some trees, of comparatively small size, are valuable on account of the quality of their timber, which is used for veneering, or for turnery Some trees, chiefly valuable as fruit trees, may also

be reckoned amongst timber trees, although not of great importance, of which the apple tree may be mentioned as an instance.

TI'MBREL (Spanish *tamburil*), a small musical instrument, of the drum species, in use in ancient times, which was carried in the hand, and was apparently not unlike the modern Tambourine (q. v.), with or without bells.

TIMBU'KTU, a famous city of Sudan, occupies a position of the highest commercial importance on the great north-western bend of the Niger; lat. 17° 37′ N., long. 3° 5′ W. It stands only a few feet above the level of the Niger, and at a distance of about six miles from the principal branch of that river, is triangular in shape, is from 2½ to 3 miles in circumference, and at present without walls, though in former times it covered a much greater area, and was defended by walls. It is laid out mostly in straight, but partly in winding streets of hard sand and gravel, and having a sort of gutter in the middle. There are three chief squares. There are about 980 clay houses — some low and unseemly, and others rising to two stories, and exhibiting considerable architectural adornment—and about 200 huts of matting, almost all in good repair. In the north of the city is the mosque of Sánkoré, an edifice of great grandeur, and which imparts an imposing character to the whole district in which it stands; and the other chief buildings are the 'Great Mosque,' an immense edifice of stately appearance, 286 feet in length, by 212 feet in width; and a few other mosques. The climate is not considered very healthy. T. is not a manufacturing town, almost the whole life of the city being based upon foreign commerce, for which its situation renders it the most favoured centre. The quantity of corn raised here is much too small to supply local consumption, and almost all the victuals used are imported by water-carriage from Sansanding, on the Upper Niger. The only manufactures carried on are blacksmiths' work, and articles in leather, especially luggage-bags, cushions, tobacco-pouches, and guncovers. Most of the clothing sold here is imported from Kano, Sansanding, and England. There are three great highways for foreign commerce to the city of T.—down the river from the south-west, and by two roads from the north, from Morocco and Ghadames respectively. Of this commerce, gold, which arrives at this place chiefly in the form of rings, is the staple; and the amount which the city exports is set down at about £20,000 yearly. Salt, and the kola-nut, which is used in place of coffee (see Tea), are also largely imported and re-exported, as are also tobacco and dates. Rice and corn are brought from Sansanding; English manufactures, consisting of red cloth, sashes, looking-glasses, cutlery, and calico, arrive from the north and north-west. The regular pop. of T. is 13,000; with floating pop., during the months of the greatest traffic and intercourse, from 18,000 to 23,000.

T. was founded about the end of the 11th c., and first became known to Europeans in 1373.—Barth's *Travels in Central Africa*, 1858.

TIME, in Music, is used in three different senses: 1. The relative duration of musical sounds as measured by the rhythmical proportion of the different notes, a minim being half of a semibreve; a crotchet, half of a minim; a quaver, half of a crotchet, &c. 2. The division into measures or bars, and the division of each measure into equal parts, and subdivision of these parts; the different combinations of sounds into equal measures and values being said to form different kinds of time, each indicated by a distinct rhythmical signature. 3. The degree of movement—that is, the absolute, and not relative velocity, which is now more generally expressed by the Italian word *tempo*.—For time in the first two senses, see Rhythm; in the third sense, Tempo.

TIMES, The, is the largest and most important daily newspaper in England and in the world. It was founded towards the end of the last century by Mr John Walter, a London printer. In January 1785, he established *The Daily Universal Register*, which he continued to publish until January 1788, when he changed the name to *The Times, or Daily Universal Register*, afterwards shortened to the *Times*. The publication, until the close of the century, remained undistinguished by any extraordinary merit or success. But in 1803, a son of Mr Walter, also named John, became joint-proprietor and sole manager; and under his guidance it soon became remarkable for the accuracy and freshness of its news, and the independence with which it expressed opinions on social and political questions. Reporters and correspondents were engaged with great discrimination, and their best services were secured by prompt and liberal remuneration. The younger Mr Walter acted himself as manager and editor. In 1805, the *Times* made an attack on Lord Melville's administration at the Admiralty, and the Walter family were in consequence deprived of the lucrative post of printers to the Board of Customs, which they had held for 18 years. At that time, there was, in consequence of the war, a great demand for continental news. The letters of the *Times*' correspondents abroad were transmitted through the regular channels, but the packets were stopped by the government, and Mr Walter was informed that he would be supplied as a favour, like the other newspapers, with official information. He declined to avail himself of this offer, and it was then he took means to secure the special and early transmission of news for his paper. His success was remarkable; and on many occasions the public dispatches were anticipated. Thus, the *Times* announced the capitulation of Flushing two days, and the result of the battle of Waterloo some hours, before the arrival of the regular dispatches. An increased circulation was the reward of these efforts, and the only limit to the increase of circulation was the impossibility of throwing off a sufficient number of copies of the paper by the hand-printing press. Mr Walter saw the importance of introducing steam-printing, and so early as 1804, he encouraged an ingenious compositor, named Martyn, to complete a machine he had invented; but Mr Walter the elder, who was then alive, was less sanguine, and the scheme fell to the ground. Some years later, Frederick Koenig, a German, invented and patented a new press, which could be worked by the steam-engine, and Mr Walter became his patron. He gave him, in 1814, an order for two machines, which, in anticipation of opposition on the part of the pressmen, were put up in premises adjoining the office. On November 29, in the same year, it was announced to these men that the paper had been printed by steam, and that there was no further occasion for their services. It is very creditable to the proprietors of the *Times* that no advantage was taken of the violent language used by the workmen on this occasion, and that their wages continued to be paid while they remained without employment. Under the old mode of going to press, about 250 copies could be printed per hour; but with the new machine it was possible to take 1100 impressions in the same time, so that the *Times* had a means of increasing its circulation not at the command of the other newspapers. From this time, Mr Walter intrusted the superintendence of the literary department of the

paper to Mr Thomas Barnes, the first editor, born in 1785, who remained in the same situation until his death in May 1841. Mr Barnes wrote few articles, but he fixed on the subjects to be discussed, and displayed great ability in giving uniformity of tone and point to the articles passing through his hands. It was during his editorship that a series of leaders by Mr Edward Sterling obtained for the paper new political and social influence, recognised by the name then applied to it, of 'the Thunderer.' It was in his time, too (1834), that O'Connell attacked the accuracy of the *Times*' reports of the parliamentary debates, and was signally defeated by the testimony of those whose speeches were said to have been tampered with.

In 1841, Mr John T. Delane succeeded Mr Barnes as editor, and continued to conduct the paper until 1877, when he resigned, and was succeeded by Mr Chenery. It was in 1841 that the *Times*, which had always sought to obtain the most accurate commercial intelligence, won a new title to the confidence of the mercantile community, by the detection of a great scheme to defraud the leading banking-houses. If Mr O'Reilly, the Paris correspondent, had not discovered the conspiracy, which was headed by a French baron, and other persons holding a good position in society, it was shewn that the leading banking-houses would have been defrauded to the extent of a million sterling. The *Times* did not altogether escape punishment. It had to defend an action at law, in which, although a verdict for a farthing of damages only was given, the defendants were obliged to pay their own costs. To relieve them of this burden, £2700 were in a very short time subscribed by the bankers and merchants chiefly of the city of London. The offer of this sum was declined, and it was in consequence employed in another way, to commemorate the event which had led to its being collected. Two sums of £1000 each were devoted to found *Times*' scholarships at Oxford and Cambridge in connection with Christ's Hospital and the City of London School; and the balance was employed to erect marble tablets at the *Times*' office and the Royal Exchange, recording the obligations the mercantile community were under to the proprietors for the generous manner in which their interests had been protected. After the death of Mr Barnes, Mr Walter did not relax his efforts to obtain early intelligence. In 1842, a remarkable instance of the trouble and expense he incurred with this view, was brought under public notice. The news of the massacre in the Cabul Pass was first made known in the *Times*. The correspondent's letter containing it had been forwarded from Marseille to Paris by carriages specially hired; from Paris to Boulogne by horse; thence to Dover by the steamer belonging to the newspaper (which had been for days in the Channel with steam up); and from Dover to London again by horse. The letter reached the *Times*' office at 2 o'clock on Sunday afternoon, and was immediately put in the hands of compositors, who had been kept in attendance from the preceding day, in expectation of its arrival. The only news of the event which had reached England at the meeting of the House of Commons next day was that contained in the *Times*, and it was at once assumed by the government as having all the authenticity of a dispatch received by the ordinary channels. The cost of conveying this letter from Marseille to London was upwards of £300. The most remarkable events in the history of the *Times* since this period are the publication of the letters from Mr W. H. Russell, the special correspondent, from the Crimea in 1854, from India in 1857, from America in 1861, and from Bohemia in 1866; the establishment of the *Times*' fund for the relief of the soldiers in the Crimea (£15,000 of which was collected in a fortnight); the formation of a fund, in 1858, for the relief of the homeless poor, when £8000 was collected in a few days for the destitute in London, and £20,000 for charitable institutions elsewhere. Within this period, important mechanical improvements were introduced in the printing-office, still further to hasten the publication of the paper; and now from 40,000 to 50,000 copies are thrown off per hour. The prosperity of the paper continues unabated, and may be fairly attributed to the literary merit of the leading articles—the value of correspondence like that describing the recent war in Bohemia, of which no satisfactory account appeared elsewhere, the accuracy of the reports, the care and good taste displayed in their revision, the respect with which honest opinion is treated, and above all, perhaps, to the absence of that sarcastic or abusive tone towards classes and sects, and that harsh literary criticism, by which other publications have obtained popularity.—See Chambers's *Book of Days*, vol. i. p. 607; vol. ii. pp. 137, 566, 567, 632, 633.

TIME-TABLES. See BRADSHAW'S GUIDE.

TIMO'LEON, a great Greek general, and the liberator of Sicily from the dominion of 'tyrants,' belonged to one of the noblest families of Corinth, and was born there about 394 B.C. T.'s brother Timophanes, having made himself tyrant of his native city, T. either killed him with his own hand, or caused him to be killed. Opinion was divided in Corinth as to the merit of this deed, one party extolling it as an act of the noblest patriotism, while the other demanded T.'s death as a murderer. The difficulty was got over by appointing him leader of a small band of mercenaries sent (344 B.C.) to Syracuse, the exiled citizens of which had begged assistance from Corinth, the mother-city, against the 'tyrant' Dionysius and the Carthaginians. Outwitting the Carthaginians, T. arrived safely at Tauromenium, where he was welcomed by the Syracusan exiles. Hicetas, 'tyrant' of Leontini, was then striving to dispossess Dionysius, and secure the tyranny of Syracuse for himself, and had succeeded in getting possession of the whole city except the island citadel. T., with only a fifth of the number, defeated him at Adranum; and marching to Syracuse, made himself master of two quarters of the city. From this time onwards, T.'s career in Sicily was one of complete victory over all opponents. Dionysius the Younger (q. v.), in 343 B.C., surrendered in despair the citadel of Syracuse, and was sent to Corinth. Hicetas having failed in the attempt to assassinate T., called in the assistance of a Carthaginian force of 50,000 men, which, however, was shortly after withdrawn by Mago, who had become suspicious of treachery. Hicetas at last fled to Leontini, leaving T. sole master of Syracuse. After repeopling the almost desolate city by recalling exiles, and inviting new colonists from Greece Italy, and Sicily, he spent the next two years in enacting laws and organising a constitution, which he put on a completely democratic footing. The Carthaginians, alarmed at the reviving power of Syracuse, and the prospect of union among the Sicilian Greeks, now sent an army of 80,000, under Hasdrubal and Hamilcar, to subdue the whole island. T., with only 12,000, encountered them (339 B.C.) on the Crimissus, and gained one of the greatest victories ever won by Greeks over barbarians. He now proceeded with his great project of expelling the tyrants of the other Greek cities, who, however, again called in the aid of the Carthaginians; but the successes of T. soon made the Carthaginians

glad to conclude a treaty, fixing the river Halycus as the boundary between their dominions and those of the Greeks. Hicetas, tyrant of Leontini, being now captured, was put to death with his wife and daughters; and shortly after, Mamercus of Catana suffered the same fate. T. thus in about six years freed Sicily from nearly all its tyrants, and conferred upon the cities free constitutions, himself all the time taking no advantage of the immense influence which he thus obtained. After his great work was accomplished, he lived among the Syracusans as a private citizen, receiving from them and from all the Greek world the greatest honour and respect: his advice was had recourse to by all the Sicilian cities in any emergency. He died in 337 or 335 B.C., having been blind for a considerable time previously; and was buried in the market-place of Syracuse, where a gymnasium, called the Timoleonteum, was afterwards erected over his tomb. T. was undoubtedly one of the greatest generals and noblest characters produced by Greece; he appears to have been thoroughly unselfish, and to have set before him as his great aim the abolition of tyranny, and the establishment of freedom.

TIMON THE MISANTHROPE was a native of Athens, and lived in the time of the Peloponnesian War (431—404 B.C.). The little that is known concerning him is learned chiefly from Aristophanes and the other comic writers who attacked him. Disgusted with mankind, on account of the ingratitude of his early friends and companions, he lived a life of almost total seclusion from society, his only visitor being the 'bold and insolent' Alcibiades. Numerous stories were current in antiquity regarding his eccentricities, one of which is, that he died because he would not allow a surgeon to visit him to set a limb. His grave, which was on the sea-shore, is said to have been planted with thorns, and to have been rendered inaccessible by the sea forming it into a small island.

> We know him out of Shakspeare's art,
> And those fine curses which he spoke—
> The Old Timon with his noble heart,
> That strongly loathing, greatly broke.
>
> TENNYSON.

'The Timon of Plutarch and of the popular stories of Shakspere's time was little different from the ordinary cynic. The Timon of Shakspere is essentially high-minded and generous, his all-absorbing defect—the root of those generous vices which wear the garb of virtue—being the entire want of discrimination. If Timon had possessed one friend with whom he could have exchanged confidence upon equal terms, he would have been saved from his fall, and certainly from his misanthropy.'—See Introductory Remarks to *Timon*, in Knight's Shakspere.

This T. must be distinguished from the Greek poet and philosopher of the same name, who lived about a century and a half later.

TIMO'R, the most important of the chain of islands which stretch eastward from Java, lies in 8° 16′—10° 25′ S. lat., and 125° 25′—127° 10′ E. long., has an area of 8820 sq. m., and pop. of about 400,000. A chain of wood-clad mountains runs throughout its entire length; Alas, on the south-east, being 11,800 feet in height; Lakaan, in 9° 10′ S. lat., 6175 feet; and Miomaffo, 4630. The prevailing rocks are of the graywacke formation, which, at the south base of Miomaffo, is cut by serpentine mountains of limestone; and calcareous rocks resembling ruins frequently occur. Magnetic iron, porphyry, syenite, gold, copper, malachite (containing 22 per cent. of pure copper), sulphur, and naphtha, are found.

The dry monsoon is from May to November, during which no rain falls. From November to April, there are daily storms of rain and wind from the north-west; the streams are swollen; the thermometer rises to 94°.4 F. in the shade; the earth is covered with a dark-green carpet, and myriads of insects come into life. The rivers are numerous but small, and most of them yield gold. Near the sea, are very fertile lands, on which are grown rice, maize, beans, tobacco, sugar-cane, cotton, potatoes, and all sorts of tropical fruits. There are many varieties of the palm, the lontar being useful for food and other purposes. Timber trees suited for masts attain a height of 100 feet, and from 3 to 4 in diameter; the wild nutmeg, cinnamon, and tamarind are plentiful; and bamboos make the forests impenetrable in many parts. About 600 species of plants are known, a great number being medicinal, and few poisonous. Indigo grows everywhere, and potatoes in the mountains.

Three-fourths of T. on the south-west is subject to the Dutch, whose chief settlement is Koepang (Kūpang); the remaining part in the north-east belongs to the Portuguese, who have a town called Dilly, on the north coast, with a safe roadstead, and a fort, which was nearly destroyed by an earthquake in 1857. T. is divided into small kingdoms, ruled by rajahs under Dutch or Portuguese control.

Koepang lies at the base of a semicircle of wooded hills, on a beautiful bay in the south-west. It is irregularly built, the principal buildings being the governor's house and the Protestant church. There is a Mohammedan and a Chinese temple, one Dutch, and two Malay schools. Pop. 3500, including 100 Europeans and 500 Chinese. Whalers and trading-ships from Sydney, Van Diemen's Land, &c., call for provisions on their way to or from Java and Singapore; and T. will be a convenient market for horses and supplies to the settlements in North Australia, which is only eight days' sailing distant.

The exports are—sandal-wood, horses, wax, tortoise-shell, edible nests, &c.; imports—cotton, woollen, and silk fabrics, provisions, and general supplies. Pearls are found on a bank 30 miles south-east from Koepang. The natives are partly Oceanian negroes, and partly of Malay race. They worship a supreme being called 'Lord of the Sun.' Near the Netherlands' settlements, some hundreds have been baptised, but missionary efforts have not been very successful. The fathers dispose of their daughters for gold and buffaloes, and polygamy prevails among the rich.

Koepang is the capital of the Netherlands' residency or government of T., which includes Samao, Rotti, Savu, the Sandal-wood Island, Sumbawa, Flores, Adanara, Solor, Lomblem, Ombay, and all the small islands belonging to the chain.

TIMO'R-LAUT, THE, or TENIMBER ISLANDS, lie east from Timor, in 6° 40′—8° 23′ S. lat., and 130° 26′—132° 2′ E. long., having an area of 3150 sq. m. Pop. 15,000. By far the largest island of the group is Timor-Laut, which is 78 miles in length, and 21 in breadth. The soil is rich, and covered with the most luxuriant vegetation, various palms and other useful trees growing in great abundance. At a little distance from the shore, mountains encircle the island.

The next in importance is Larat, the north-west point of which is in 7° 6′ S. lat., and 131° 47′ E. long. Area, 147 sq. m.; pop. 2500. It is also mountainous. Further north are Vorhate, Marū, and Molo. On the west of Timor-Laut are Selū and Sejrah; a multitude of smaller islands of coral formation being scattered around.

On the larger islands are small horned cattle, goats, swine, fowls, and a great variety of birds.

Nothing can exceed the beauty of the Blue-streaked Lory (*Eos reticulata*) and the Citron-crested Cockatoo (*Cacatua citrino-cristatus*). Fish are plentiful in the rivers of T. and surrounding seas, and there is a considerable export trade in tortoise-shell and Bêche-de-Mer (q. v.). English trading-ships from Singapore, and South-sea whalers, sometimes visit these islands, and not unfrequently have been treacherously attacked. The natives are tall, well made, fairer-complexioned, and have more regular features than the Alfoors. They are low in the scale of civilisation.

TIMOTHY, FIRST AND SECOND EPISTLES TO, form, along with the Epistle to Titus (q. v.), the three 'Pastoral Epistles,' the authorship of which is all but universally ascribed to St Paul. The external evidence for their genuineness is very strong, yet not complete. They occur in the Muratorian Canon and the Peshito version as writings of St Paul; Eusebius classes them among the *homologoumena;* while still earlier, Irenæus, Tertullian, and others of the Fathers quote them as authoritative. On the other hand, Tatian (q. v.), one of the earliest of the Fathers, denies their genuineness, as did also Marcion, Basilides, and most of the Gnostic teachers. Origen speaks of some who rejected 2d T. on account of the mention of 'Jannes and Jambres,' two apocryphal characters; while in modern times, Schleiermacher and Neander admit the Pauline origin of 2d T., and endeavour to disprove the genuineness of 1st. Eichhorn, De Wette, Baur, and others go further, and seek to demonstrate the spuriousness of the whole three Pastoral Epistles. They consider the language and mode of thought quite distinct from the Pauline, and they (particularly Eichhorn) find no period in the apostle's life to which they could be properly fitted in. Their conclusions, however, cannot be said to have seriously affected the convictions of scholars. The purpose and scope of the Epistles to T. are so well known, that an analysis, however slight, is almost superfluous. They consist of a series of warnings, exhortations, advices, and predictions.—See the 'Introductions' of Alford, Wordsworth, Davidson, Wiesinger, Hug; and the list of commentators on the 'Pastoral Epistles,' appended to the article on the Epistle to TITUS.

Timothy Grass (*Phleum pratense*).

TIMOTHY GRASS, the name commonly given to *Phleum pratense*, a grass much valued for feeding cattle. It first received the name T. G. in America, from the name of a person who did much to promote its cultivation there. Along with the other species of the genus, it often receives also the English name of CAT'S-TAIL GRASS. The genus *Phleum* is distinguished by a panicle so compact as to resemble a close spike, single-flowered spikelets, with two nearly equal acuminate or almost awned glumes, two awnless paleæ, and the seed free. The species are mostly natives of Europe; a number of them are British, but the T. G. alone is of any economical value. It varies very much in size according to soil and situation, succeeding best in moist rich soils. It is very extensively cultivated both in Britain and in America. It has strong culms, attaining a height of 4—5 feet, but is tender and nutritious, and much relished by cattle. It is perennial, but springs up rapidly, even in the year in which it is sown. Its spikelike panicle, from the form of which the name Cat's Tail has been given, is cylindrical, and often of several inches in length. The seed is very small.—*Phleum nodosum* is a very similar species, perhaps a mere variety, with the lower part of the culm prostrate and swollen into knots or bulbs; the spike much smaller than in *P. pratense.* It is a very inferior grass, and is found only on dry soils.

TIMUR, called also TIMUR-BEG and TIMUR-LENG from his lameness, and vulgarly known among western writers as TAMERLANE, was the second of the great conquerors whom Central Asia sent forth in the middle ages, and was born near Kesh (Shehri-Sebz), April 8, 1336. His biographers make him the fifth in descent from Karatchâr Nuyan, the relative and counsellor of Genghis Khan (q. v.), and the ninth from Tûmna Khan, the direct ancestor in the male line of his renowned predecessor. The royal line of Jagatai (see TURKESTAN) had so utterly degenerated that the real power was in the hands of a number of independent chiefs of Mongol blood, each of whom, choosing a prominent city of the kingdom, there set up his standard, and lorded it over the surrounding district. One of these chiefs, Hadji Berlas, the uncle of T., had established himself at Kesh, and here the future conqueror passed the first 24 years of his life in peaceful obscurity, devoting himself to the national amusements of hunting and equestrianism. But a formidable inroad (1360) of the Kalmucks of Jettah, who speedily subjugated Turkestan, expelling those chiefs who refused submission, effectually called forth T.'s hitherto untried energies. Declining to accompany his uncle in his flight, he boldly advanced with a small retinue to meet the invader, who was so charmed with his eloquence and address, that he at once confirmed him in the government of Kesh, and appointed him one of the principal ministers of his son, the new monarch of Turkestan. But neither chiefs nor people of the conquered country could long endure the tyranny of a race more cruel and barbarous than themselves, and the exiles and fugitives having been collected by the Ameir Husseyne, and joined by a powerful force under T., the Kalmucks were ultimately expelled in 1365, and Turkestan divided between its two liberators, who ruled together in the utmost harmony for some time; but war having arisen between them, Husseyne was defeated and slain, and T., by unanimous consent of the chiefs, was hailed as supreme lord of Turkestan. It was in the war against the Kalmucks that T. received the wound in the thigh which rendered him lame for the rest of his life. He did not, however, either then or afterwards, assume the rank of a sovereign, but elevating one of the royal race to the throne, reserved for himself the real authority and the title of *emir.* Having thus, in the space of ten years, risen, by dint of superior ability, to absolute authority over a numerous and warlike people, he proceeded to avenge his nation's wrongs on the Kalmucks of Jettah and Mogulistan; then turned westward to punish the predatory tribes of Khaurezm, who had plundered Bokhara; and spent the interval between these campaigns in supporting Toktemesh Khan, one of the claimants to the throne of Keptchak, ultimately (1376) placing him in undisputed possession. With the view of restoring its former

limits to the empire of Jagatai, he summoned the prince of Herat and the other chiefs of Northern Khorassan to attend a 'kouriltai;' and on their refusal, immediately attacked and reduced them to submission, levying a moderate contribution as a penalty. But soon after (1383), the people of Herat again rebelled, murdered the envoys whom he sent to remonstrate; and 2000 of the garrison, built up with an alternate layer of brick and mortar into the form of a pyramid, were left by T. as a horribly singular and effective reminder of the consequences of rebellion. Seistan was next reduced, the Afghans of Suliman Koh chastised, and T. returned, as was his wont, to spend the winter in the bosom of his family, at one or other of his numerous palaces near Samarkand. In the following year, he commenced his career of aggression by the invasion of Mazanderan; and by the close of 1387, the whole of the districts west of the Tigris, from Tiflis to Shiraz, were subdued; those chiefs who voluntarily submitted being mostly confirmed in their governments, while the inhabitants of Ispahan—who, after a pretended submission, suddenly rose upon the Tartar garrison, and massacred 3000 of them—were almost completely exterminated. Meanwhile, Toktemesh Khan, of Keptchak, took advantage of his absence to invade T.'s territories on the Amu-Daria; on which T. returned home, and, after driving the invaders out, pursued them to the head of the Tobol, then west across the Ural mountains and river, and though long baffled by the Arab tactics of his opponents, finally brought them to bay on the banks of the Bielaya (a tributary of the Kama), 18th June 1391, and almost wholly annihilated them. Resuming, in 1392, his conquering march westwards, he crossed the Tigris, subdued the numerous and warlike principalities to the east of the Euphrates, then advanced northwards, through the gates of Derbend, to the Volga, and again routed Toktemesh (who had ventured to resume hostilities), on the banks of the Terek (1395), turned west as far as the Dnieper, and then north to Moscow, returning by Astrakhan and the Caucasus, leaving death and desolation in his track. In 1398, T. campaigned in Hindustan, entering by the passes of the Hindu Koh, near Cabul, and routing *seriatim* the numerous armies collected to oppose him, till the number of prisoners became so great, that four days before the great battle before Delhi between T. and the Indian emperor, the former, as a precautionary measure, ordered the murder in cold blood of all the males (said to be 100,000 in number), and then, after totally routing his opponents, took the capital. After a further advance to the Ganges, and more military successes, T. retraced his steps to Samarkand, where the immense spoils of the expedition were expended in the adornment of the capital. T. returned to Western Asia in the following year, and attacked the Egyptian Empire in Syria, to avenge the murder of his ambassador, and the aid which the Mamluk sultan had given to his enemies. T. was as usual completely successful in the field; and the capture of Aleppo, Hama, Hems, Baalbek, and Damascus, equally proved his skill in the attack of fortified places. His mode of attack was to undermine the fortifications on all sides, then to fire the mines with wood steeped in naphtha, and on the destruction of the walls and battlements, which uniformly resulted, to charge in overwhelming force through the breaches. Similar conduct to that of the Mamluk sultan on the part of Sultan Bajazet I., drew from T. repeated remonstrances, which the other, in the overweening confidence springing from uninterrupted success, treated with contempt, and answered with insult; but the advance of the Tartars to his frontiers soon opened his eyes to the greatness of his error, and with a powerful army, he hastened to oppose them. The two hosts met at Angora (July 20, 1402), and after a long and obstinate contest, in which, although the generalship of Bajazet and the steadiness of 20,000 Servian auxiliaries long balanced the superiority of T.'s troops, the Turks were totally routed, and Bajazet captured. The conquest of the whole of Asia Minor speedily followed; the Byzantine emperor did submission to the victor, as did also the Turkish ruler of Thrace; and the Knights of St John were expelled from Smyrna. The unfortunate Bajazet died after a few months' captivity, though uniformly treated with the greatest consideration; and about the same time, T. commenced his return—receiving on the way a most satisfactory embassy from the Egyptian sultan, who was now glad to come to terms—conquering Georgia, where he passed the winter, and resuming his march in the following year by Merv and Balkh, reached Samarkand in 1404. Here he resumed preparations for the long projected invasion of China, continued the embellishment of the capital, and celebrated his great successes by the most gorgeous festivities. All things being now ready, he started with a large army for the Sihun, marched down that river to Otrar, where, being detained by the severity of the weather, he was attacked by an ague-fever, and died after a week's illness, February 17, 1405. T. holds a high position as a mere conqueror: his antagonists were mostly warlike and disciplined, and seldom much inferior in number; yet, from the savage horsemen of the Siberian steppes to the mailclad warriors of Servia, all were alike forced to bow before the invincible prowess of the Mongol conqueror. The charge of cruelty brought against him is completely established by the massacre in India, but opposite to this might be placed numerous instances of a lenity and forgiveness almost incredible in a 'barbarian.' He did much to promote the arts and sciences throughout his dominions, but the speedy dissolution of his empire deprived his labours of any permanent utility.—The principal authority for the life of T. is Sherif-ed-Din-Ali's *History* (in Persian), translated into French by Pétis de la Croix, under the title of *Histoire de Timur-Bec, connu sur le nom du grand Tamerlan* (4 vols., Par. 1722). Several writings exist in Persian, attributed to T., but are of doubtful authenticity. Among these are the *Institutions* (with an English translation and a valuable index, Oxford, 1783); and the *Commentaries* of T., translated from a MS. of Major Davy by Major Stewart, late Professor of Oriental Languages in the East India Company's College. See also a translation of the narrative of Clavijo, envoy of Henry III. of Castile to T., by C. R. Markham (Hakluyt Society, 1860).

TIN (symb. Sn,* equiv. 118, spec. grav. 7·29) is a beautiful silvery-white metal, with a tinge of yellowish blue, and a high metallic lustre. It possesses a crystallised texture, and may be obtained in well-formed crystals of the pyramidal or tetragonal system; and it is in consequence of this crystalline texture that a bar of tin, when bent, emits a creaking sound, termed the *cry* of tin (the *Zinngeschrei*, or tin-shriek of the Germans). Tin is a soft metal—being softer than gold—and is very malleable, and can be beaten out into very thin laminæ, in which form

* This symbol, as well as the word *stannic*, is derived from the Latin *stannum*, tin; the symbols T and Ti, either of which would at first sight seem more appropriate, being engaged to designate Terbium and Titanium respectively.

it is known as *tinfoil.* At a temperature of about 212°, its ductility is considerable, but by no means remarkable, and it may be then easily drawn into wire, the tenacity of which is only moderate, as a wire with a diameter of 0·17 of an inch is broken by a weight of about 50 lbs. It is a tolerably good conductor both of heat and electricity, and when handled communicates a peculiar odour to the skin. It melts at a temperature of 442°; and at a higher temperature, if air be present, it becomes converted into the dioxide, and burns with a brilliant white light. At ordinary temperatures, it is very slightly acted on by exposure to the air, or to moisture. With regard to the action of the ordinary acids of this metal, Professor Miller observes that 'nitric acid of specific gravity 1·3 acts upon it violently, and produces an insoluble hydrated binoxide, known as metastannic acid; at the same time, owing to the decomposition of water, a considerable quantity of ammonia is formed, which enters into combination with the excess of acid. Strong hydrochloric acid, when heated upon tin, dissolves it gradually, with extrication of hydrogen. Aqua regia, if not too concentrated, dissolves the metal, and converts it into bichloride. Dilute sulphuric acid is without action on the metal in the cold; but if the concentrated acid be boiled upon it, the tin becomes converted into sulphate, while sulphurous acid escapes. The hydrates of potash and soda act upon tin at high temperatures, hydrogen being evolved, whilst a soluble metastannate of the alkali is formed.' —*Inorganic Chemistry*, 2d ed., p. 588.

Tin is met with in only a few localities, and never occurs native. The metal is extracted from the ore by a series of operations described below.

There are three oxides of tin—viz., the Protoxide, or Stannous oxide (SnO), the Sesquioxide (Sn_2O_3), and the Dioxide, or Stannic oxide (SnO_2).

Protoxide of Tin, or stannous oxide (SnO), is obtained as a brown or black powder, by precipitating protochloride of tin with carbonate of sodium and heating the washed and dried precipitate in an atmosphere of hydrogen or carbonic anhydride to about 176° F. With acid it forms stannous salts, from whose solution in water crystalline tin is deposited on an inserted mass of zinc, constituting the so-called *Tin Tree.* None of these salts are of any special importance. *Dioxide of Tin*, or stannic oxide (SnO_2), occurs native in the anhydrous form, crystallising in square prisms, which are sufficiently hard to scratch glass, and generally of a brown colour, from the presence of peroxide of iron or of manganese. In its artificially prepared, hydrated condition, it has the character of an acid, and according to its different modes of preparation, forms two remarkable varieties, known as stannic and metastannic acids. *Metastannic Acid* is prepared by the action of strong nitric acid on tin, and occurs as a white, crystalline, insoluble mass, which, when dried in air, consists of $Sn_5O_{10}.5H_2O$, but when dried at 212°, loses half its water, and consists of $Sn_5H_{10}O_{15}$, or $Sn_5O_2.5H_2O$. By ignition, it becomes anhydrous, and of a pale straw colour. In this form (in which it resembles the native dioxide in its properties), it is known in commerce as *putty-powder*, and is employed for polishing plate, and for giving whiteness and opacity to enamels. In the hydrated state, it is insoluble in hydrochloric or nitric acids, but is freely soluble in solution of potash or soda, forming salts which are not crystalline, but may be obtained in a granular form. Metastannic acid, in its hydrated state, may be recognised by the beautiful golden yellow metastannate of tin which is formed when it is moistened with protochloride of tin. *Stannic Acid* ($SnO_2.H_2O$) is procured by the addition of carbonate of calcium or of barium to a solution of tetrachloride of tin, when it falls as a gelatinous precipitate. Unlike metastannic acid, it is readily soluble in nitric and hydrochloric acids; and at a temperature of 284°, it is converted into metastannic acid. In combination with the alkalies, it forms stannates, which crystallise readily, and whose formula is M_2SnO_3. The stannate of sodium (Na_2SnO_3) is largely used as a mordant by the dyer.

There are three chlorides of tin—viz., a Dichloride, or Stannous, Sesquichloride, or Stannoso-stannic, and Tetrachloride, or Stannic. *Hydrated dichloride of Tin* may be obtained by dissolving the metal in hydrochloric acid, and evaporating the solution, when the salt crystallises in prismatic needles, having the composition $SnCl_2.4H_2O$. The hydrated dichloride is extensively used as a mordant, and for deoxidising indigo and the peroxides of iron and manganese, by the dyer and calico-printer; and in consequence of its deoxidising or reducing powers, it is sometimes employed in analytical chemistry, especially in the determination of the quantity of mercury, since all the mercurial salts, when boiled with it, are decomposed, and yield their mercury in the metallic form. *Tetrachloride of Tin* ($SnCl_4$) forms numerous soluble salts with the soluble chlorides; the compound of this nature which it forms with chloride of ammonium is represented by the formula $2NH_4Cl.SnCl_4$, and is employed by the dyer under the technical term of *Pink Salt.* An impure tetrachloride prepared by dissolving tin at a gentle heat in a mixture of nitric acid and sal-ammoniac, and known in the trade as *Nitromuriate of Tin*, or *Composition*, is also largely used by dyers and calico-printers.

The sulphides of tin are three in number—viz., the protosulphide, the sesquisulphide, and the disulphide, or sulpho-stannic acid. The *Hydric Sulpho-stannate of Tin* ($HS.SnS_2$) may be obtained in the form of a dingy yellow precipitate, by passing sulphuretted hydrogen through a solution of a persalt of tin. In the dry way, it is procured in the form known as Mosaic Gold, which is insoluble in any acid, though soluble in aqua regia; and is employed in the arts to give an appearance of bronze to the surface of metals.

Tin forms two sets of salts—the protosalts or stannous and the persalts or stannic, of which the protochloride and tetrachloride of tin may be taken as good examples. The *Stannous* salts yield a very characteristic reaction with sulphuretted hydrogen, a chocolate-coloured precipitate of hydrated protosulphide of tin being thrown down; moreover, with a dilute solution of trichloride of gold, they give either a beautiful purple precipitate, known as the *Purple of Cassius*, or a brown precipitate of reduced gold, according to the quantity of the test that is used. The *Stannic* salt yields a dirty yellow precipitate of hydrated disulphide of tin; while all the compounds of tin, when exposed on charcoal to the reducing flame of the blowpipe, give a white malleable globule of the metal.

Reduction and Manufacture.—Tin must have been one of the metals earliest known, as it enters into the composition of Bronze (q. v.), of which the most ancient metallic weapons and tools were made. Tin and oysters were the products for which Great Britain was earliest famous. It is nearly all obtained in Cornwall; and from that locality the Phœnician navigators took it to Tyre and Sidon. To this day, England is by far the greatest tin-producing country, having raised in 1869 about 15,000 tons of dressed ore, or 10,000 tons of the metal. Bohemia and Saxony have some tin mines, and so also have Spain and Portugal. Tin has long been obtained from Malacca, in the Malayan Peninsula, and from some of the neighbouring islands. Australia among her other mineral riches produces tin, but the export of ore from that country has not yet exceeded 600 tons a year. Tin has recently been found in California and in Missouri, and in very minor quan-

tities elsewhere in the United States; but it is probable that Great Britain will long continue to supply the demand.

There is but one ore of tin of any importance—viz., the dioxide (SnO_2), which in its pure state consists of tin 78, and oxygen 22. It is called Tinstone or Cassiterite. Tin ore has nothing remarkable in its appearance; it is of various colours—as gray, various shades of yellow, and red, and black. Its specific gravity—a notable feature—is 6·9; and it strikes fire with steel. In Cornwall, the tin ore occurs in mineral veins running through granite and slate rocks, or disseminated in crystals through their mass. The tinstone obtained from the veins or lodes is called *Mine-tin;* and that procured by washing alluvial deposits is called *Stream-tin*—the latter is the result of the disintegration of granite and other rocks which contained veins of tin. Washed Cornish tin ore, usually called 'black tin,' produces on an average about 67 per cent. of metallic or 'white' tin. Tin pyrites, or sulphuret of tin, is found in some of the Cornish mines, but it is of little importance commercially. It may also be stated that ores containing copper are sometimes found with so large a proportion of tin that it is difficult to say whether they should be regarded as tin or copper ores.

The dressing of tin ore obtained from the mine is a difficult and delicate operation. It is so much dispersed through the gangue, that it requires to be stamped to a very fine powder by apparatus described under METALLURGY, before the metallic particles can be effectually separated. So small comparatively is the valuable portion of the ore, that at Huel Kitty Mine, St Agnes, not more than 84 lbs. of oxide of tin is obtained from a ton of the material brought to the surface; and in some mines, the proportion of oxide to the rest of the material is not so much as 10 lbs. to the ton.

The stamped ore is copiously supplied with water passed through a grating adjoining the stamps, and conveyed into a channel where there are two pits. The purer and heavier portion falls into the first, and is called the *crop;* the remainder, called the *leavings*, passes through the first, and is retained in

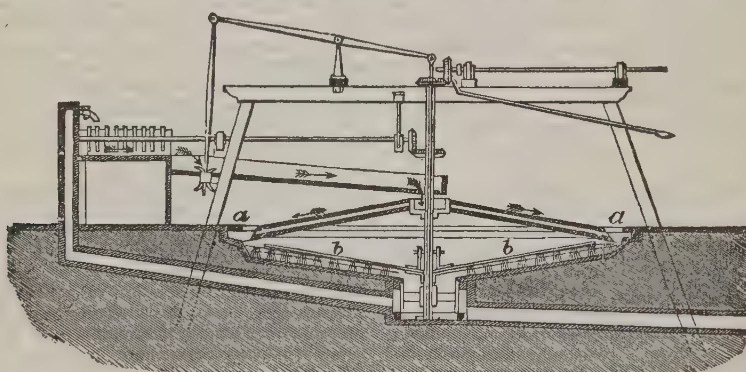


Fig. 1.

the second pit. Repeated washings are now necessary to separate as thoroughly as possible the impurities from the ore, and for this purpose a machine called a *buddle* is largely employed. Various kinds of apparatus are, however, used, but they are similar in principle to the jigging sieve and sleeping table described under METALLURGY. We may notice here that a new form of buddle, known as 'Borlase's Buddle,' has been recently introduced for dressing tin ores, by which a saving of about 30 per cent. is said to be effected. Figs. 1 and 2 shew this machine. The ore and earthy matters, in the state of a thick mud, are conveyed by square pipes or channels to the circumference *a*, *a*, around which, by the aid of water, the metallic portion separates, while the lighter stony impurities flow towards the centre, and are carried away. There are brushes at *b*, *b*, for agitating the ore during the operation. In the older form of buddle, this action is reversed, and the machine, instead of being depressed, is raised in the centre.

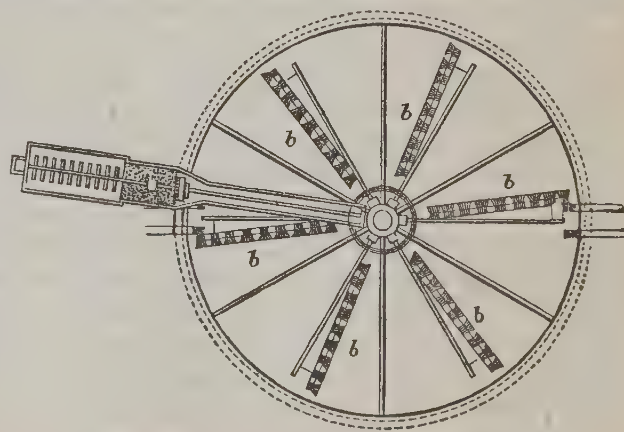

Fig. 2.

The tin ore thus far purified, has next to be deprived of its sulphur and arsenic; this is done in a Reverberatory Furnace (q. v.), the flues of which are connected with large condensing chambers, in which the arsenic is deposited in a crystalline form (see ARSENIC), and is afterwards resublimed, to form the white arsenic of commerce. The sulphur, which is present in the state of sulphuret of iron, is decomposed by the heat into sulphurous acid gas and the remaining oxide of iron is removed by a subsequent washing. Sulphuret of copper, when

present, is converted by roasting, and afterwards exposing it to the air, into sulphate of copper, and is then easily dissolved out by lixiviation.

After this final washing, the ore is ready for smelting in a reverberatory furnace. The charge consists of from 20 to 25 cwts. of ore mixed with one-sixth of its weight of powdered anthracite or charcoal, and a small quantity of lime or fluor-spar, to serve as a flux for the siliceous impurities. Before being put into the furnace, the mixture is moistened with water, to prevent the finely-powdered ore being carried away by the draught. When the charge is placed on the hearth of the furnace, the doors are closed, and the heat gradually raised for about six hours; the oxide is then reduced by the carbon of the coal. At this stage, the furnace-door is opened, and the mass worked with a paddle, to separate the slag, which is raked off, and the richer portion of it melted over again. The reduced tin subsides to the bottom, and is run off into a cast-iron pan, from which it is ladled into moulds, to produce blocks or ingots of a convenient size.

The tin has still to be purified, first by a process of *liquation*, and afterwards by that of *poling*. 'Liquation' consists in moderately heating the blocks in a reverberatory furnace till the tin, owing to its comparatively easy fusibility, melts, and flows into the refining-basin, leaving on the hearth of the furnace a residuary alloy of tin with iron and other metals. More blocks are added, and heated in the same way, till the refining-basin contains about five tons. The tin is then ready for 'poling.' In this operation, billets of green wood are plunged into the melted metal, the disengagement of gas from which produces a constant ebullition, and so causes a scum (chiefly oxide of tin) to rise to the surface, which is then easily removed; at the same time, impure and dense parts fall to the bottom. When the agitation has gone on long enough, the bath is allowed to settle and cool. The tin then separates into zones—the upper consisting of the purest portion; the middle being slightly mixed with other metals; and the lower so much so, that it requires to go through the refining process again. The residuary alloy of the liquation process has also its tin extracted and refined again.

In former times, in Cornwall, tin was smelted in a Blast Furnace (q. v.) instead of a reverberatory one; and this is still the case on the continent. By this method a pure tin is obtained, but the loss of metal in the process is greater. It suits best where coal is scarce and wood abundant.

Tin ores which contain the mineral wolfram (tungstate of iron and manganese) are treated by a special process, patented by Mr R. Oxland of Plymouth. This mineral and tin ore are so nearly the same in specific gravity, that no mechanical process of washing will separate them. Mr Oxland's process consists in roasting the dressed tin ore with sulphate of soda, for the purpose of converting the insoluble tungstate of iron and manganese into the soluble tungstate of soda, which is easily removed by lixiviation. The oxides of iron and manganese, which are left in a finely-divided state, can then, from their lower density, be readily got rid of by washing. Since the invention of this process, some of the Cornish tin ores which used to sell at the lowest, now bring the highest price. The tungstate of soda procured in the operation has lately been found to be one of the most valuable substances for rendering cotton cloths non-inflammable.

Tin when heated up to nearly its melting-point, becomes brittle, and can then be broken into prismatic fragments called *dropped* or *grain tin*. The metal which is susceptible of this change may be considered to be of fine quality, as impure tin does not become brittle when so treated. The peculiar properties of tin, especially its malleability, its brilliancy, and the slowness with which it oxidises at common temperatures in the atmosphere, render it of great service in the arts. With other metals, it forms some valuable alloys—as bronze, gun-metal, bell-metal, pewter, and solder. See ALLOY. An amalgam of tin and mercury forms the metallic coating of mirrors. Tin is very largely used to coat the surface of other metals, as iron and copper. See TIN-PLATE. The applications of tinfoil, which is not more than $\frac{1}{1000}$th of an inch in thickness, are well known. In certain kinds of ornamental metal-work made in India, tin is applied instead of silver for ornamenting steel and iron. A compound of tin with gold, and also with other metals, is employed to produce crimson, purple, and pink colours on glass and pottery. Metastannic acid (see above) is used in the preparation of enamels; and under the name of *putty-powder*, is largely used for polishing plate and ornamental stones. The two chlorides of tin are prepared on a large scale for dyers and calico-printers.

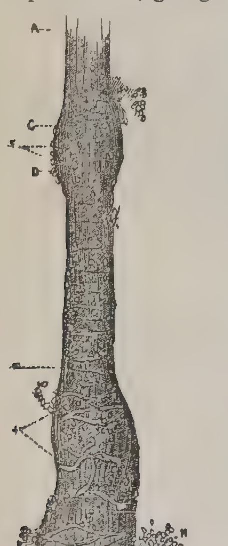
TINCAL. See BORAX.

TINCTURE. See HERALDRY.

TINCTURES are defined by Dr Christison to be 'solutions of vegetable and animal drugs, and sometimes of mineral substances in spirituous liquids. The spirit most commonly employed is proof-spirit; sometimes rectified spirit is used; and occasionally ether. Ammonia is sometimes conjoined with the spirit, in which case the solution is termed an ammoniated tincture. (It may be as well to remind the reader that *Rectified Spirit* is alcohol with 16 per cent. of water, and that its specific gravity is ·838; and that *Proof Spirit* is composed of 5 parts of rectified spirit mixed with 3 parts of water, the resulting compound containing about 47·5 per cent. of water, and having a specific gravity of ·920.) The choice between proof and rectified spirit depends on their respective solvent powers over the active principles of the drugs employed. The ether and ammonia are principally used for their antispasmodic properties. 'The form of tincture,' says Dr Christison, 'is one of the best in pharmacy; for the menstruum is a powerful solvent of the active constituents of drugs; it presents them in small volume; it preserves them very long unaltered, and it is for the most part a convenient medium for uniting them with other substances in extempore prescriptions.'

TINDAL, DR MATTHEW, a notable deistical writer, was the son of a clergyman at Beer-ferris, in Devonshire, where he was born about 1657. He was educated at Lincoln and Exeter Colleges, Oxford; took the degree of B.A. in 1676; and shortly after, was elected Fellow of All Souls' College. In 1685, he became a Doctor of Law; and after a brief lapse into Romanism during the reign of James II., reverted to Protestantism, or rather, as events shewed, into Rationalism. His first work was entitled *An Essay concerning Obedience to the Supreme Powers*, &c. (Lond. 1693); followed in the course of a few months by *An Essay concerning the Laws of Nations and the Rights of Sovereigns*; but it was not till 1706 that he attracted any particular notice, when the publication of his treatise on *The Rights of the Christian Church asserted against the Romish and all other Priests who claim an independent power over it; with a Preface concerning the Government of the Church of England, as by Law established*, raised a storm of opposition, that may perhaps be considered to have fulfilled the prediction of the author, who told a friend that 'he was writing a book which would make the clergy mad.' A

perfect torrent of replies and refutations poured from the press. Among those who signalised themselves as the adversaries of T., the least obscure were Dr G. Hickes and Conyers Place. Swift, it may be noticed in passing, also indulged in some 'Remarks.' On the continent, T.'s work was quite differently received. Le Clerc, in his *Bibliothèque Choisie*, praises it very highly, as one of the solidest defences of Protestantism ever written. In 1730, when he had nearly reached the age of 73, he published his most celebrated treatise, entitled *Christianity as old as the Creation, or the Gospel a Republication of the Religion of Nature*, which effectually settled the question of his religious creed. The design of the work is to strip religion 'of the additions which policy, mistake, and the circumstances of the time have made to it'—in other words, to eliminate the *miraculous* element, and to prove that its morality, which is admitted to be worthy of an 'infinitely wise and good God,' is its true and only claim to the reverence of mankind. T.'s purpose was rather constructive than destructive; and it was on this account that he called himself a 'Christian Deist.' He was answered, among others, by Dr Waterland, Mr Foster (an eminent dissenting minister), Dr Conybeare (afterwards Bishop of Bristol), and Dr Leland (q. v.), with various degrees of ability and success. T.'s book is written in excellent English, and is unquestionably a very able performance, giving its author a distinguished place among the 18th c. deists. T. died 16th August 1733.



Fungus in *Tinea decalvans*: AF, lower part of an affected hair, highly magnified; FG, its root; C, spheroidal swelling due to accumulation of spores, E, between the longitudinal fibres of the hair; D, rupture of long fibres; I, sporules and tubes of the parasite; H, a group of sporules proceeding from G, the ruptured root.

(From Aitken's *Science and Practice of Medicine.*)

TINDER, an inflammable material, usually made of half-burned linen. It was formerly one of the chief means of procuring fire before the introduction of chemical matches. The tinder was made to catch the sparks caused by striking a piece of steel with a flint; and the ignited tinder enabled the operator to light a match dipped in sulphur. This intermediate step was necessary in consequence of the impossibility of making the tinder flame. Partially decayed wood, especially that of willows and other similar trees, also affords tinder; and certain fungi furnish the German tinder, or Amadou (q. v.).

TINEA is a term somewhat vaguely employed to designate certain parasitic diseases of the skin, and especially of the scalp. Three of the most important varieties of tinea, viz., *T. circinatus* (ringworm of the body), *T. tonsurans* (ringworm of the scalp), and *T. sycosis* (ringworm of the beard), have been already described in the article RINGWORM (q. v.). In these three varieties, which are included in the general term *T. tondens*, the vegetable parasite known as *Trichophyton tonsurans*, figured in the above article, is always present. It now remains to notice the *Tinea decalvans* of Bateman, known also as *Porrigo decalvans*, *Alopecia circumscripta*, &c. It is defined by Aitken as 'a fungus disease, causing the formation of rounded or oval patches of baldness, sometimes solitary, more generally multiple. It affects the hairy scalp principally; but the beard and hairy portion of the skin may also suffer.'—*The Science and Practice of Medicine*, 2d ed., vol. i. p. 925. The fungus which causes these patches of baldness was detected by Gruby in 1843, and named the *Microsporon Audonini*. It differs from the *Trichophyton* by its numerous waved filaments, and the extremely small size of its sporules, and likewise by its position, not being found in the interior of the root of the hair, but forming a little tube round each hair, and thus causing it to soften and break down. The hairs thus affected become dull and partially loose; the skin in which they are implanted becomes red, swollen, and slightly itchy; and a whitish matter (the sporules of the fungus) may soon be observed on the diseased skin and hairs. The hairs then suddenly fall off from the affected part, leaving a round bald patch of a very white colour. The disease is capable of transmission from one person to another, although less readily than *Tinea tonsurans*. It chiefly affects children. The treatment consists in preventing the spread of the disease by extracting the hairs round the circumference of the patch, and washing the head daily with soft soap; and all the young hairs within the patch must be extracted till a healthy crop begins to appear. Moreover, a solution of sulphurous acid, as recommended for ringworm, should be applied. When by these means the fungus has been destroyed, stimulants must be applied to the bald patches. A mixture of equal parts of *Collodium* and of *Ether cantharidalis* (*Collodium vesicans*) is, according to Dr Aitken, the most useful stimulant in these cases.

TINEI'DÆ, a family of small moths, the smallest insects of the lepidopterous order. The body is long and slender, the wings entire, often narrow, mostly convoluted in repose. Many of them are very brilliantly coloured, exhibiting beautiful little stripes and patches of gold and silver. Many deposit their eggs in animal substances, on which the larvæ feed, making cases for themselves out of the substance they feed on. The Clothes Moths (q. v.) are a familiar example.

TI'NGI (*Magonia glabrata*), a tree of the natural order *Sapindaceæ*, which covers large tracts of country in some parts of Brazil, to the exclusion of almost everything else, generally growing to the height of 30 or 40 feet, but sometimes much higher. An infusion of the bark of the roots is used to poison fish. The fruit is a large dry triangular capsule, filled with broad flat seeds, from which a kind of soap is made. The membrane which covers the cotyledons is stripped off, and they are steeped in water till they begin to swell and soften, and boiled with a little tallow. A homogeneous mass is formed, which is used for washing clothes.

TI'NKER'S ROOT (*Triosteum perfoliatum*), a shrubby plant of the natural order *Caprifoliaceæ*, a native of North America, the root of which is used as an emetic and mild cathartic. It derives its name from Dr Tinker, who first brought it into notice.

TI'NNITUS AU'RIUM is the Latin translation of, and ordinary medical term for, ringing in the ears. In most cases, it is an unimportant symptom, depending on some local temporary affection of the

ear, or on some disturbance of the digestive system with which the part of the brain, from which the auditory nerve springs, sympathises, or which excites the cerebral circulation (as often occurs in the morning after too liberal evening potations); but as it is also a common symptom of organic disease of the auditory nerve, it may indicate a dangerous condition, or may be a prelude to complete deafness. Hence, although commonly of no consequence, it is a symptom that, especially if permanent, must be carefully watched. It may be readily induced for a few hours by a large dose of quinia.

TI'NOS, or TINO (anc. *Tenos*), an island in the Grecian Archipelago, belonging to the group of the Cyclades, lies immediately south-east of the island of Andros, 53 miles off the coast of Bœotia. It is 18 miles long, 8 miles in extreme breadth, has an area of 81 sq. m., and a pop. of 21,171. The Tenians were conspicuous among the ancient Greeks for their industry, and they still maintain their preeminence in that respect. The island is carefully cultivated, well watered, has a delightful climate, and is very productive in silk, wine, barley, and fruits. Silk gloves and stockings are manufactured; and the inhabitants have made themselves famous as workers in marble, which is found in the island. In the modern town of Tenos, or St Nicholas, is a cathedral built of white marble, and famous as a resort for pilgrims.

TIN-PLATE. The manufacture of this article forms a branch of the iron trade. The art of tinning plate-iron is said to have been invented in Bohemia, about the beginning of the 16th c., although the tinning of copper was known some time earlier. Tin-plate was first made in England about the year 1670.

Sheet-iron for tin-plates is made either of charcoal-bar or coke-bar, which has been rolled with particular care, in order to avoid scales on the surface. Before tinning, the plates are called 'black plates.' When the iron has been cut to the required size, the plates are 'pickled'—that is, they are immersed in hot sulphuric or hydrochloric acid which has been diluted by 16 parts of water to 1 of acid, the use of the acid being to remove all oxide and other injurious matter. After this, the plates require to be washed several times in water; and then follows an annealing in closed cast-iron boxes in a reverberatory furnace, where they are subjected to as high a heat as they will stand without softening. The next operation consists in passing the plates two or three times through chilled iron rollers highly polished with emery and oil, so as to give them a well-polished surface. This both saves tin and gives them a good appearance when finished. Once more they are sent to the annealing furnace, passed again through dilute sulphuric acid, which is followed by another washing, but this time in running water, and then scoured with sand. This should leave them quite clean and bright for the tinman.

Each plate is now put singly into a pot of melted grease (which has become sticky by use), and left till it is completely coated, after which the plates are taken in parcels and plunged into a bath of melted tin covered with grease, called the 'tin-pot.' They pass from this to another vessel with two compartments called the 'wash-pot,' both of which contain melted tin of the purest quality, and like the last, covered with grease. The plates are put into the first compartment in parcels, where they receive a coating of purer tin than that of the 'tin-pot,' and are then withdrawn one by one, and wiped on both sides with a hemp brush; the marks of which are obliterated by another dipping in the second compartment of the 'wash-pot.' This last dipping also gives the plates a polish. The next thing is the removal of the superfluous tin, which is generally two or three times more than what is left on the plate. It is done by immersing the plates, in an upright position, in a pot containing tallow and palm oil, maintained at a temperature no higher than will keep the tin in contact with the oil liquid, and so allow it to run off. The final treatment consists in working the plates separately in troughs of bran with a little meal, and then rubbing them with flannel.

There is a variety of tin-plates called 'terne-plates,' coated with an alloy of tin and lead, in which the proportions vary from 1 of lead and 2 of tin to 2 of lead and 1 of tin. They are largely exported to Canada, where they are used for roofing.

The imports of tin and its manufactures entering into consumption in the United States in 1870 amounted to $9,721,000.

TI'NSEL OF THE FEU, in the Law of Scotland, means an irritancy or forfeiture of a feu-right caused by the failure to pay the feu-duty for two whole years. A statute of 1597 authorised, in such a case, the superior to take steps to obtain a decree of declarator that the feu was forfeited; but the vassal might, any time before decree, purge the irritancy by paying the arrear.—TINSEL OF THE SUPERIORITY is a similar remedy which a vassal has against the superior who has not got himself infeft, so as to be in a position to complete the vassal's title. In such a case, the tenant may under the statute 1474 charge the superior, that if he do not within forty days obtain infeftment, he shall lose the tenant or vassal for his (the superior's) lifetime, and thereby all the casualties that may fall to the superior from the act or delinquency of such vassal.

TI'NTERN ABBEY, a famous ecclesiastical ruin on the right bank of the Wye, in Monmouthshire, about 9 miles south-south-east of Monmouth. The Abbey—properly so called—was founded in 1131 for Cistercian monks, by Walter de Clare, and dedicated to St Mary; but already in the previous century a church had been built, and in 1268, mass was celebrated by abbot and monks for the first time. The style of architecture is a transition from Early English to Decorated, and is very fine. Most of the building, except the roof and tower, remains. T. A. owes not a little of its celebrity to Wordsworth's poem, entitled *Lines composed a few Miles above Tintern Abbey, on revisiting the Banks of the Wye*—though in reality the poem has nothing whatever to do with the Abbey, which is not once mentioned or alluded to in it.

TINTORETTO, a Venetian historical painter, so called from the fact of his father being a dyer (*Tintore*), but whose real name was JACOPO ROBUSTI, was born in 1512. He studied for a short time under Titian, but appears to have been for the most part self-taught. His motto was a very fine one: *Il disegno di Michael Angelo, e 'l colorito di Tiziano* (The design of Michael Angelo, and the colouring of Titian); but it cannot be said that he adhered to it, and he is certainly a long way inferior to either artist. Still, his assiduity, when young, in acquiring a varied knowledge of the human figure under all possible aspects of light and shade, commands respect, in spite of the theatrical means to which he often resorted; and the rapidity of his pencil (which got him the name of *Il Furioso*) is at least astonishing. Sebastian del Piombo remarked that T. could paint as much in two days as he could do in two years. A catalogue of T.'s works, specimens of which are to be found in almost

all galleries, is impossible within our limits. We can only mention a few of the more famous, as 'Belshazzar's Feast, and the Writing upon the Wall' (fresco, for the Arsenal at Venice), 'The Tiburtine Sibyl,' 'The Last Supper and the Washing of the Disciples' Feet,' 'A Crucifixion,' 'The Worship of the Golden Calf,' 'The Last Judgment' (the last two immense pictures 50 feet high, and very splendid in conception), 'St Agnes restoring to Life the Son of a Prefect,' 'The Miracle of St Mark,' a 'Resurrection of Christ,' 'The Slaughter of the Innocents,' and a grand picture of 'Paradise'—34 feet high by 74 long, with upwards of 100 figures. Some of T.'s earlier pictures are very carefully finished, but his later ones are dashed off with a fatal haste, that justifies the remark of Annibal Caracci, that if he 'was sometimes equal to Titian, he was often inferior to Tintoretto.' T. lavishly indulged in *chiar' oscuro*, but his colouring is not gay or brilliant; it is rather cold and leaden, as might be expected of a painter who, when asked what were the prettiest colours, replied: 'Black and white.'

TIPPECANOE′, a river of Indiana, U. S., which rises in a lake of the same name in the northern part of the state, flows south-west 200 miles, and empties into the Wabash 9 miles above Lafayette. It is famous for the battle fought on its banks, November 5, 1811, in which the Indians, under Tecumseh's brother, the prophet, were defeated by General Harrison.

TIPPERA′RY, an inland county of the province of Munster, Ireland, bounded on the S. by Waterford; and on the W. by Cork, Limerick, Clare, and Galway. Area, 1659 sq. m., or 1,061,731 acres, of which 843,837 are arable, 178,183 uncultivated, 2359 in towns, and the rest under plantations and water; pop. in 1871, 216,210, of whom 202,798 were Catholics, 13,412 Protestants, including Presbyterians and other sects of Christians. The population in 1881 was 199,612. In the year 1872, the number of acres under crops of different kinds was 280,082. In the same year the cattle numbered 228,760; sheep, 263,081; and pigs, 97,264. The inhabitants are mostly engaged in agriculture. The total value of property is £675,587. The number of children attending schools in the county of T. in 1871 was 41,802, of whom 40,598 were Roman Catholics, 1066 of the Established Church, and the rest of other denominations.

The county of T. for the most part lies in the basin of the river Suir. This river rises near Templemore, in the north of the county; and after traversing T. a distance of about 76 miles, forms for a time its boundary with Waterford, through which county it ultimately passes to the sea. The other rivers of T. are the Nore, the Nenagh, and the Brosna. The lakes are numerous, but of small size. The county is intersected by the Great Southern and Western, and the Limerick and Waterford Railways. The surface is generally plain, and the mountains which diversify it are rather groups than portions of any connected range. These mountains are the Galtees, rising to 3000 feet, Knockmeledown (2700 feet high), and Slievenaman on the south; Keeper Mountain, 2100 feet high, and its group on the west; and the Slievardagh Hills on the east. There is one very curious isolated height called the Devil's Bit, to which many popular legends attach. The soil of the plain is a rich calcareous loam, singularly fertile and productive, especially a district called the Golden Vein, in the centre of which stands the town of Tipperary (q. v.), and which extends from Limerick to the county of Kilkenny. There is another similarly fertile district in the north of the county. In geological formation the plain belongs to the great central limestone district. The mountains are for the most part of clay-slate, surrounded or surmounted by sandstone; the Galtees, together with a contiguous group called Slievenamuck, as well as the intervening valley, being sandstone. There is a large amount of bog in the central and eastern districts, one continuous tract extending a distance of thirty miles. The mineral productions are coal (anthracite), copper, and lead, also zinc and very good fire-clay; and slates of an excellent quality are quarried near Killaloe. Wheat was formerly grown in large quantities; but of late years dairy-farming and the raising of cattle have been rapidly taking the place of the production of cereals. Flax is but sparingly produced.

The county, which sends two members to the House of Commons, is divided into two ridings, North and South, each of which is subdivided into six baronies.

Anciently, T. formed part of the two distinct principalities of Ormond, or North Munster, and Desmond, or South Munster: after the English invasion, T. was formed into a county by King John in 1210; but the authority of the conquerors was long little more than nominal. Eventually, it came to be divided between the Anglo-Norman families of Butler, which held Ormond, and Geraldine, to whom a portion of Desmond fell. The antiquities are numerous, as well Celtic as Anglo-Norman. In the latter, the city of Cashel is specially rich; and the ruin of Holy Cross is a noble specimen of the monastic remains of the medieval period, as the castle of Cahir is of the military and baronial architecture of the same age. There is a series of caves near the border of the county of Cork, in the vicinity of Mitchellstown, which attract much notice as a natural curiosity. They consist of a number of chambers and galleries formed by stalactite deposits, one portion of the range being no less than 870 feet in length.

TIPPERARY, a market-town of the county of the same name, on the river Arra, 111 miles south-west from Dublin by the mail-coach road, and 110 by the Great Southern and Western Railway, with which it is connected by the Limerick and Waterford Railway. T. occupies a central position in a fine county, and carries on, therefore, an extensive trade in butter. The pop. in 1871 was 6084; town-rates levied £120. The town is of very ancient foundation, and soon after the invasion was occupied as a strong place by the English, who built a castle in it during the Irish expedition of King John. This castle, however, fell soon afterwards into the hands of the Irish under the Prince of Thomond. The town is well built, but of no architectural pretensions, and contains a large and handsome Roman Catholic church, a Protestant church, a Presbyterian meeting-house, two National Schools, and one school of the Erasmus Smith endowment.

TIPPOO SAHIB, sultan of Mysore, and son of Hyder Ali (q. v.), was born in 1749. Efforts were made to carefully instruct him in the various branches of learning cultivated by Mohammedans; but T. much preferred the practice of athletic exercises, and the companionship of the French officers in his father's service, from whom he acquired a considerable acquaintance with European military tactics. This knowledge he put to effective use during his father's various wars, by completely routing Colonel Bailey at Perimbakum (10th September 1780), and (18th February 1782) Colonel Braithwaite on the banks of the Kolerun in Tanjore, though these were his only important engagements with the British

forces in which he could boast of success. On the death of his father, he was crowned with little ceremony, returning at once to the head of his army, which was then engaged with the British near Arcot. On 28th April 1783, he captured and put to death most of the garrison of Bednore; but news of the peace between France and England having reached his French allies, they retired from active service, and T. ultimately agreed to a treaty (11th March 1784), stipulating for the *status quo* before the war. During the continuance of this peace, he occupied himself in regulating the internal administration of Mysore, sent ambassadors in 1787 to France to stir up a war with Britain, and failing in this, at length so far allowed his inveterate hatred of the English to overcome his judgment, as to invade (April 1790) the protected state of Travancore. In the ensuing war (1790—1792), the British, under Colonel Stuart and Lord Cornwallis, were aided by the Mahrattas and the Nizam, who detested their powerful and aggressive neighbour equally from fear and religious hatred (T. being a fanatical Mohammedan); and though the tactics of the sultan in laying waste the Carnatic almost to the very gates of Madras, baffled his opponents for a time, he was ultimately compelled (16th March 1792) to resign one half of his dominions, pay an indemnity of 3030 lacs of rupees, restore all prisoners, and give his two sons as hostages for his fidelity. Nevertheless, his secret intrigues in India against the British were almost immediately resumed; another embassy was sent to the French; and the invasion of Egypt by the latter in 1798, and T.'s machinations, having become known to the governor-general almost contemporaneously, it was resolved to punish the perfidious sultan. Hostilities commenced in March 1799; and two months after, T. was driven from the open field, attacked in his capital of Seringapatam, and after a gallant resistance, slain. He was buried in his father's mausoleum, 5th May 1799, during a storm of thunder and lightning, which caused the death of several Europeans and natives. His government of Mysore after 1792 was of a most oppressive character, yet T. was extremely popular, and after his death was esteemed by the Mohammedans as a martyr to the faith of Islam. Of the chief articles of *virtù* with which his palace abounded, many are now in Fife House, Whitehall (having been lately removed thither from the East India House in Leadenhall Street), as also the half of his library, the other half being preserved at Fort-William, Bombay.

TI'PULA AND TIPU'LIDÆ. See CRANE-FLY.

TIRABOSCHI, GIROLAMO, an eminent Italian author, was born at Bergamo, 28th December 1731, studied at Monza, and afterwards entered the order of the Jesuits. Towards 1766, he was appointed Professor of Rhetoric at Milan, where he wrote his first work, *Vetera Humiliatorum Monumenta* (1766); and in 1770 succeeded Father Granelli in the post of librarian to the Duke of Modena. T. now availed himself of the rich stores of the ducal library, besides making extensive researches in other archives, to compose his *Storia della Letteratura Italiana* (History of Italian Literature), which began to appear in 1772, and was finished in 1783 in 13 vols. It embraces the history both of ancient and modern Italy, and is especially valuable for the light which it throws upon the intellectual condition of the Peninsular during the dark ages, and the brilliant period from Dante to Tasso. T. ends his elaborate survey with the close of the 17th century. It is impossible to praise too highly the learning and the conscientious accuracy of the author, even although the circumstances that many of the epochs have since been made the subject of minute and special inquiries, necessitates a revision of parts of the work. A second edition was edited by T. (1787—1794), and abridged translations have appeared in French and German. The best edition is that published at Milan (16 vols. 1822—1826). A continuation embracing the literature of the 18th c. was written by Lombardi (*Storia della Letteratura Italiana nel Secolo XVIII.*). T. died at Modena, June 3, 1794. Other works by this author are *Biblioteca Modenese* (6 vols., Mod. 1781—1786); and *Memorie Storiche Modenesi* (3 vols., Mod. 1793).

TIREE', one of the Inner Hebrides, included in Argyleshire, lies 20 miles north-west of Iona. It is 13 miles long, and over 6 miles in extreme breadth. The surface is low, rising in the north to little more than 20 feet, and in the south to about 400 feet above sea-level. The absence of trees and shrubs gives to the island a bleak appearance. There are numerous small lakes. Upwards of 5000 acres are under tillage, while 10,700 acres are in pasture or waste-land. Some interest attaches to the island from the number of Scandinavian forts which dot the shores, and from the standing-stones, ruined churches, and ancient graves which occur in the interior. Pop. (1871) 2834, who support themselves by rearing cattle, fishing, and exporting poultry and eggs.

TIRE'SIAS, in Greek Mythology, figures as a famous prophet, who, according to one legend, was struck blind by the goddess Athena, because he had seen her bathing. Another legend represents Hera as depriving him of his sight because, being made arbiter in a dispute between her and Zeus, he had decided in favour of the latter; when Zeus as a compensation granted him the inner vision of prophecy, and prolonged his life for several generations. He is consequently prominent in many of the mythical stories of Greece, but at last found death by drinking from the well of Tilphosa. Even in Hades, T. retained his prophetic power.

TIRLEMONT (Flemish, *Thienen*), a town of Belgium, in South Brabant, on the Great Geete, 38 miles east-south-east of Brussels, on the Brussels and Cologne Railway. The church of St Germain, on an eminence, dates apparently from the 9th c., and contains an altar-piece by Wappers. Beer and hosiery are manufactured. T. was ravaged by Marlborough in 1705; and here the French, under Dumouriez, defeated the Austrians in 1793. Pop. about 12,500.

TI'RNOVA, a town of European Turkey, in Bulgaria, on the Jantra, 35 miles south-south-east of Sistova. It was formerly the chief town of Bulgaria, and the seat of considerable manufactures, and whatever rank it now holds it owes to its central position. There are numerous mosques, churches, and synagogues; dyeing is carried on, and silk and coarse cloth are manufactured. Pop. variously stated at from 12,000 to 16,000.

TI'RYNS, an ancient city of Argolis, in the Peloponnesus, one of the very oldest cities of Greece, situated a short distance south-east of Argos, near the head of the Argolic Gulf. According to the common tradition, it was founded by Prœtus, a mythic king of Argolis; and its massive walls, like other rude massive structures in Greece of unknown antiquity, were reputed to be the work of the Cyclopes. Prœtus is said to have been succeeded by Perseus; and in this place Hercules was believed to have passed his youth. At the time of the Trojan War, T. appears to have been subject to the kings of Argos. Some time subsequently to the battle of Platæa (to which the Tiryntians sent troops), probably about the year 468 B. C., the city

was taken by the Argives, and entirely destroyed; and after this period, T. remained uninhabited, the walls of the citadel only being left standing, the wonder and admiration of later ages. T. affords one of the most interesting specimens of what is called Cyclopean architecture, the ruins of this place, and those of the neighbouring city of Mycenæ, being the grandest of all in Greece. The Acropolis, or citadel of T., was built on the summit of a low, flat, rocky hill, rising abruptly out of the dead level of the plain of Argos, and appears to have consisted of an upper and a lower enclosure of nearly equal size, with an intermediate platform. There were two main entrances, on the east and on the south sides, with a postern on the west. The entire circuit of the walls still remains more or less preserved; they are upwards of 20 feet in thickness, and are formed of unhewn stones of enormous size, rudely piled in tiers one above the other, without the use of mortar or cement, the interstices being filled up with smaller stones, so as to make the whole mass solid and compact. There are several covered galleries of singular construction in the body of the wall, on the east and the south sides, the roof being formed by sloping the courses of masonry on each side of the passage at an angle to each other. One of them has six recesses, or niches, on the outer side of the walls, intended probably to facilitate defence. Altogether, in the words of Colonel Mure, 'this colossal fortress is the greatest curiosity of the kind in existence.'

TI'SANE, TISAN, or PTISAN, an infusion made of certain herbs, leaves, or flowers, used as tea for medicinal purposes. It is a very favourite form of remedy in the domestic medicine of France.

TISSUES, Animal, may be either normal or pathological. The most important of these tissues have already been considered in special articles, and we shall here merely notice the view at present most generally adopted regarding their classification (see Histology). The normal tissues are divisible, according to Virchow and his followers, into three groups or categories. We have (1) tissues which consist exclusively of cells, when cell lies close to cell; or (2) tissues in which one cell is regularly separated from the others by a certain amount of intermediate matter, or intercellular substance; or (3) tissues in which the cells have attained specific, higher forms of development, by means of which their constitution has acquired an entirely peculiar type. As illustrations of the first group of tissues, the simple cellular tissues in the modern sense (cellular tissue here being quite distinct from areolar or connective tissue), we may take the epithelial formation, such as occur in the epidermis and the nails, and in the epithelium of mucous and serous membranes, in the crystalline lens of the eyes (which is originally a mere accumulation of epidermis), and in the glands. The second group is formed by the connective tissue, which is composed of intercellular substance, with cells of various forms embedded in it, and includes cartilage, fatty tissue, &c. In the third group, which is somewhat heterogeneous, the structures are usually more or less tubular. This group includes the muscles, nerves, and vessels, and Virchow also places the blood in it. Such an arrangement as this is quite distinct from, and altogether at variance with, those adopted a comparatively few years ago. *This* arrangement has reference to General Histology (*tissues*, properly so called), while *that* has reference to Special Histology, or the structure of organs in which a combination of various tissues may enter. Thus, the *osseous tissue* of general histology consists of bone-cells + calcified intercellular substance, while *bone as an organ* consists of osseous tissue + medullary tissue + periosteum + vessels + nerves; similarly, nervous tissue is by no means identical with cerebral matter, which additionally contains membranes, vessels, &c.

Morbid tissues may be classified upon exactly the same plan as the physiological or normal tissues. The belief is gradually extending that there is nothing peculiar or specific in pathological structures, or, in other words, that every pathological tissue has its physiological prototype, and that 'no form of morbid growth arises which cannot in its elements be traced back to some model, which had previously maintained an independent existence in the economy.'—Virchow's *Cellular Pathology*, translated by Chance, p. 60. The distinguished pathologist whose words we have just quoted, maintains that there is no other kind of heterology in morbid structures than the abnormal manner in which they arise, and that this abnormity consists either in the production of a structure at a point where it has no business, or at a time when it ought not to be produced, or to an extent which is at variance with the typical formation of the body; 'but,' he adds, 'practical experience shews us that it would be altogether incorrect to conclude from the mere correspondence of a pathological tissue with a physiological one, that the case would continue to follow a benignant course.' The curious bodies provided with large nuclei and nucleoli, which have been described by many pathologists as 'the specific polymorphous cells of cancer,' are merely irregularly developed epithelial cells, such as occur, for example, in the lining of the urinary passages; and the apparent heterology of other morbid growths may be similarly explained.

TISSUES, Vegetable. See Cellular Tissue, Vascular Tissue, and Vegetable Tissues.

TIT, or TITMOUSE (*Parus*), a genus of birds of the order *Insessores*, tribe *Conirostres*, and family *Paridæ*. The *Paridæ* are small birds, of which there are more than 50 known species, widely distributed throughout Europe, Asia, Africa, and North America. They are more numerous in cold and temperate than in tropical regions, those which are found within the tropics being mostly inhabitants of elevated mountainous districts. The bill is small, short, somewhat conical, the tip entire, the base beset with hairs, and the nostrils generally concealed by feathers. The wings are not very long, but are pointed; the tail is rounded or even; the tarsi long, slender, scaled in front, the inner toe shortest, the claws long and curved. The plumage is beautiful, often gay. The popular names Tit and Titmouse are very generally given to all the *Paridæ*. They are bold sprightly birds, extremely active, flitting from branch to branch, running rapidly along branches in quest of insects, and often clinging to the under-side of branches with their back downwards. They feed not only on insects but on grain and seeds, have no objection to carrion, and sometimes kill young and sickly birds by strokes of their bill. They are very pugnacious, and the female Tit shews great courage in defence of her nest, often continuing to sit when the nest is approached, and vigorously assailing the intruding hand with her bill. In winter, many of the species gather into small flocks, and approach houses and villages, competing with sparrows and chaffinches for a share of the food of domestic poultry. Most of the tits lay at least six eggs, some of them twelve or more, and even in temperate countries they often produce two broods in a year. They generally build in trees. The young are fed chiefly on caterpillars. A pair of Blue Tits have been observed to carry a caterpillar to their nest, on an average, every two minutes

during the day, so that these birds must be extremely useful in preventing the multiplication of noxious insects. Seven species are found in Britain, but one of them, the CRESTED TIT (*Parus cristatus*) is a mere accidental visitor. The GREAT TIT (*P. major*) is the largest European species. It is common in almost all parts of Europe. It is not quite six

Cole Tit (*Parus ater*), and Long-tailed Titmouse (*Parus caudatus*).

inches long; the head and throat are black; the cheeks are white; the back, breast, and sides yellowish; the wings and tail grayish. Its usual note is a kind of chatter, but it sometimes imitates the notes of other birds. The BLUE TIT (*P. cœruleus*) and the COLE TIT (*P. ater*) are very common in Britain. The Blue Tit is perhaps the most pert and audacious of all the British species. It very generally receives the familiar name of *Tomtit*. The upper part of the head is light blue, and a bluish tinge prevails in the plumage. The LONG-TAILED TIT (*Parus caudatus*), common in Britain, has the tail about as long as the body. Its head is white, contrasting beautifully with the deep black of the back; the tail is also black, with white edges. The nest of this bird is a beautiful structure of moss and wool externally covered with lichens, and profusely lined with feathers, nearly oval, with a small hole in the upper part of one side. Still more interesting is the nest of the PENDULINE TIT (*Aegithalus pendulinus*) of the south of Europe, which in form resembles a flask, and is generally suspended at the end of a flexible twig, in a situation near to or overhanging water. It is nicely woven of fibres of bark and the down of willow or poplar catkins, and the opening is in the side. The CHICKADEE or BLACK-CAP TIT (*Parus atricapillus*) is very common in North America. The TUFTED TIT (*Lophophanes bicolor*) is the largest American species.

TITA'NIUM (symb. Ti, equiv. 50, spec. grav. undetermined) is a comparatively rare metal, which, according to the method by which it is procured, occurs either as a gray, heavy, iron-like powder, which burns with brilliant scintillations in the air, and is converted into titanic acid, or in prismatic crystals. At 212° it decomposes water, and it is soluble in hydrochloric acid. It is obtained in the crystalline form by heating sodium in the vapour of bichloride of titanium. It never occurs native, but is found in association with other elements in various minerals, of which the most important are *Anastase*, *Rutile*, and *Brookite*, containing titanic acid; *Titanite*, containing silicate of lime and titanic acid; *Perovskite*, containing titanite of lime; *Æschynite*, containing titanic and niobic acids, and the oxides of cerium and lanthanum; and lastly, *Titanic Iron*, composed of titanate of protoxide of iron. A remarkable artificial compound of the metal is often found in the form of copper-coloured cubic crystals, adhering to the slags of iron furnaces. They are hard enough to scratch agate; and no acid except a mixture of nitric and hydrofluoric acids has any action on them; but they are volatile at an extremely high temperature. They consist of a combination of cyanide with nitride of titanium, and are represented by the remarkable formula, $TiCy_2.3Ti_3N_2$. The most important compound of this metal is *Titanic Acid* ($H_2.TiO_3$), which occurs in the minerals *Menaccanite* and *Iserine*, as titanate of iron, but is more common in the uncombined state, as titanic anhydride, in the form of rutile, brookite, and anastase, each of which possesses a distinct crystalline form, and has a different specific gravity. Hence, titanic acid in the anhydrous state is trimorphous. It is usually obtained by a somewhat complicated process from rutile. Titanium was discovered by Gregor, as a constituent of menaccanite, in 1791.

TI'TANS AND TITA'NIDÆ (originally called *Ouraniōnes*, Celestials), in Greek Mythology, were the sons and daughters of Uranus (Heaven) and Gæa (Earth). Their names, as commonly given, were: Oceanus, Cœus, Crius, Hyperion, Iapetus, Kronos, Theia, Rhea, Themis, Mnemosyne, Phœbe, and Tethys; Dione, Phorcys, and Demeter are added by some writers. Instigated by their mother, the T., headed by Kronos, rose against their father, emasculated and deposed him, and liberated their brothers the Hecatoncheires (Hundred-handed) and the Cyclopes (q. v.), from Tartarus. Kronos being made king, threw the Cyclopes back again to Tartarus, and married his sister Rhea. In order to escape being deposed by one of his own children, as it was foretold he would be, Kronos swallowed each as it was born. Rhea, when she gave birth to Zeus (q. v.), saved his life by giving a stone wrapped in a cloth to Kronos, who swallowed it, believing it to be his child. Zeus, when he grew up, gave his father a potion which caused him to vomit the stone and the children he had swallowed. Assisted by his brothers and sisters, along with the Cyclopes and Hecatoncheires, Zeus began with the T. the ten years' conflict which resulted in the complete triumph of the former, and the overthrow of the latter, who were hurled down into a dungeon below Tartarus, surrounded by a brazen wall, and guarded by the Hecatoncheires. During the war, Zeus and his allies occupied Mount Olympus in Thessaly, his opponents being encamped on Mount Othrys.—The name T. is also given to the descendants of the T., such as Prometheus, Hecate, Helios, Selene, &c.

TITHES (A.-S. *teotha*, a tenth; Lat. *decima*, i. e., *pars*, a tenth part), the tenth part of the produce of the land, which, by ancient usage, and subsequently by law, is set aside for the support of the clergy, and other religious uses. This provision for the clergy passed at a very early period from the Jewish into the Christian Church, and indeed the same or some analogous appropriation has been traced in the other ancient religions. It is observable under the patriarchal system in the words employed by Jacob (Gen. xxviii. 22), and in the offering of Abraham to Melchisedec (Gen. xiv. 20); and mystical reasons have been devised for the selection of the tenth part, rather than any other fractional portion of the produce of the earth, to be consecrated to the uses of religion and the ministers of religion. (See Spencer, *De Legibus Hebræorum*, iii. 1—10.) The details of the institution among

the Jews will be found in Levit. xxvii., Deut. xiv., and many other places. The tribe of Levi not having lands assigned, as was the case with the other tribes, drew their support from this impost.

In the Christian dispensation, the very circumstance of the existence of the clergy as a distinct class supposed a certain fixed provision for their maintenance. The necessity of such provision, and the right on which it is founded, is distinctly expressed in many passages and allusions of the New Testament, as Matt. x. 10, Luke x. 7, Rom. xv. 27, 1 Cor. ix. 7—14. The obligation in the general sense which these passages involve has been put forward in ecclesiastical legislation from the earliest period. The apostolical canons, the apostolic constitutions, St Cyprian on *The Unity of the Church*, and the works of St Ambrose, St Chrysostom, St Augustine, and the other Fathers of both divisions of the church, abound with allusions to it. As yet, however, this obligation was discharged mainly in the form of voluntary offerings; and the legislation of the first Christian emperors, while it presupposed the duty of maintaining the clergy, and even assigned lands and other property for their support, did not extend to any general enactment for the payment of the tenth of the produce of the lands. The Council of Tours, 567 A.D.; the second Council of Macon, 585; that of Rouen, 650; of Nantes, 660; of Metz, 756; and some others, distinctly sanction that form; and at length Charlemagne by his capitularies formally established the practice within those portions of the ancient Roman Empire to which his legislation extended.

From this and other sources, the payment of a tenth to the church extended throughout Western Christendom. By some, the claim was held to be of divine law; by others, of human institution; but in the gradual progress of relaxation, it came to pass that the right thus established solely for the church began to be usurped for themselves and for purely secular uses by nobles or other powerful laymen See IMPROPRIATION.

The first introduction of tithes into England is ascribed to Offa, king of Mercia, in the close of the 8th century. The usage passed into the other divisions of Saxon England, and was in the end made general for all England by Ethelwulf. It would seem that at first, although all were required to pay tithes, it was optional with each to select the church to which his payment should be made; but by a decretal of Innocent III., addressed to the Archbishop of Canterbury in 1200, all were required to pay tithes to the clergy of their respective parishes, and this parochial distribution of tithes has ever since obtained in England. The ancient canon and civil law distinguishes many varieties of tithes, into which we shall not enter, as royal, indominicate, fiscal, salic, &c. We shall confine our remarks to the provisions of the English law, premising that in most respects it is founded upon the general principles of the civil and canon law.

Tithes are of three kinds—*prædial*, *mixed*, and *personal*. Prædial tithes are those which arise immediately from the earth itself, as of grain of every kind, fruits, and herbs. *Mixed* tithes are those proceeding from things nourished by the earth, as calves, lambs, pigs, colts, chickens, milk, cheese, eggs, &c. *Personal* tithes are those arising from the profits of personal industry, in the pursuit of a trade, profession, or occupation; but it is commonly held that personal tithes were ordinarily paid in the form of a voluntary offering at Easter or some other period of the year. From these explanations, it will be understood that no tithe was due from the proceeds of mines or quarries, as their produce is not the result of any growth or increase of the earth, but forms part of its substance; nor from houses, as having no annual increase. The common law, moreover, held wild animals, game, fish, &c., not to be proper subjects of tithe, as also tame animals kept for pleasure or curiosity, and not for profit or use.

A more arbitrary distinction is into *great* and *small* tithes, the first being tithes of corn, hay, wood, &c.; the second being the other kinds of prædial tithes, as well as all personal and mixed tithes. This distinction, although purely arbitrary, is important, inasmuch as the great tithes of a parish belong to the Rector (q. v.), and the small tithes to the Vicar (q. v.). T. were originally paid 'in kind;' that is, by the actual numeration of the products of the land, and the apportionment in each of the numerical tenth part, as of the tenth sheaf, the tenth lamb, calf, &c. The inconvenience and trouble, as well as the unsettled and variable quantities involved in this mode of payment, led to early attempts to provide other modes of apportioning the result (the particular manner being called technically a *modus decimandi*, or simply a *modus*). This was done either by making an agreement to pay a fixed quantity irrespective of actual produce in each year, or by a money payment settled between the parties; or by a partial substitution of payment or labour, as when the party contributed a smaller quantity of produce, but free from the expense of harvesting, carriage, &c.; or finally, by a payment of a bulk sum in redemption of the impost, either for a time or for ever, as the case might be, in which case the land so redeemed became temporarily or permanently tithe-free. By such compositions, many lands in England were made anciently tithe-free, and have so continued; but by 1 Elizabeth 19, and 13 Elizabeth 10, such alienations of tithe-payment were restricted to a term of twenty-one years, or three lives.

Besides the exemption from tithe thus created, a still more comprehensive occasion of immunity is traceable to the exemption enjoyed by the lands of religious houses. Originally, convents occupying lands in England paid tithes like other landowners to the parochial clergy; but a decretal of Paschal II. exempted them from such payments in regard to lands held by themselves in their own occupation. This exemption was confined by subsequent legislation to the four orders—Templars, Hospitallers, Cistercians, and Præmonstratensians, and after the 4th Council of Lateran (1215), only in respect of lands held by them before that year. Frequently, however, exemptions were given in favour of particular houses; and in cases in which religious communities were themselves the incumbents of a parish, as they could not pay tithes to themselves, their own lands within such parish became exempt by what was called 'unity of possession.' And thus it came to pass that a large extent of land in England and Wales was held free of tithes. Now, when, on the suppression of monasteries, those lands were assigned to lay possessors, they passed of course into lay hands with the same immunity; and hence this exemption from tithe has become perpetual even in the hands of lay possessors, as, on the other hand, by a similar transfer, lay proprietors have in many instances acquired the right to tithe, and the property of many rectories.

The arrangements between parties for commuting the mode of payment, to which allusion is made above, were permitted, and even protected by law; but they were nevertheless purely voluntary and partial, and the perpetually recurring contests to which the system led, as well as the oppressive nature of the exaction when the parties from whom it was claimed did not belong to the church

established by law, combined to render the impost odious and unpopular; and to such a length did this reach in Ireland, that in the end an organised and general resistance to the payment made it impossible to enforce its collection in great part of three out of the four provinces. A measure of commutation became in the end absolutely necessary. Such commutation had been recommended by committees as far back as 1822, but it was not finally passed into law until 1838. Since that time, various statutes, as well for England as for Ireland, have been enacted regulating the payment of tithe—6 and 7 Will. IV. c. 71, 7 Will. IV. and 1 Vict. c. 69, 1 and 2 Vict. c. 64, 2 and 3 Vict. c. 32, and 5 and 6 Vict. c. 54. The object of these acts for England is to substitute a rent-charge payable in money, but varying on a scale regulated by averages of the price of corn for the seven years preceding for all the other forms of payment, whether under composition or otherwise. This commutation may be voluntarily effected by the parties themselves; but failing such voluntary arrangement, a compulsory commutation is effected by the Tithe Commissioners, in accordance with a valuation and apportionment in every parish of England and Wales. Provision is also made that land not exceeding twenty acres may be given by a parish in commutation of tithes; but this can only be done in the case of ecclesiastical persons, and not for lay impropriators. Similar arrangements have been made in those few Catholic countries in which tithes still continue to be paid.

In Ireland, the settlement was effected by a general commutation of tithe into a money rent-charge, regulated by a valuation of the tithes (one-fourth being deducted for the cost of collection), and payable directly by the proprietors, to whom is left the charge of receiving it from the occupiers of the land.

TI'THING, an ancient Saxon division of the country, consisting of the tenth part of a hundred, being occupied by ten families, each of whom was responsible for the good behaviour and peace of the rest. The institution has been long growing obsolete, and the Police Constables (q. v.) now supersede the officer called a tithing-man.

TITHO'NUS, son of Laomedon, brother of Priam, and spouse of Eos, the goddess of Morn. The story is that Eos, in asking immortality for her spouse, forgot to ask at the same time eternal youth, so that in his old age he became completely shrunk and decrepit, whereby his 'cruel immortality' was rendered a burden to him.

TITIAN, or TIZIANO, VECELLI, the head of the Venetian School, and one of the greatest painters that ever lived, was born of a good family at Capo del Cadore, in the Friulian Alps, in the year 1477, or, according to some, in 1480. His predilection for drawing caused his father to send him to Venice at the age of ten, that he might learn to be a painter. His instructors were Sebastiano Zuccati and the two Bellinis, particularly Giovanni; but the painter that exercised the greatest influence on his style was Giorgione (q. v.). So vivid and keen was his appreciation of the distinctive features of any artist's work, that he never failed to reproduce them with striking fidelity, and even to leave the impression that he had beaten the master whom he imitated, in his own style. It was owing to this irrepressible superiority that the friendship between Giorgione and him was interrupted. The first work that brought T. prominently into notice was his completion of the 'Homage of Frederick Barbarossa to Pope Alexander III.' (1512), begun by Giovanni Bellini, but left unfinished by that artist at his death. The Venetian senate, who had commissioned the piece, were so much pleased with T.'s performance, that they conferred on him an office with an annual salary of 300 crowns. In 1514, he painted 'Bacchus and Ariadne,' and other works of a similar kind, for the Duke of Ferrara, a portrait of the duke himself, and of the lady who afterwards became his wife, besides a picture of the 'Tribute-money.' While residing at the court of Ferrara, he made the acquaintance of the poet Ariosto, who sat to him for his portrait. On his return to Venice, he painted an 'Assumption of the Virgin,' one of his grandest achievements. His reputation now rapidly rose. Pope Leo X. and Raphael both invited him to Rome, and Francis I. to France; but he declined. During 1520—1530, the most celebrated of his numerous productions were—'St Peter, Martyr,' a work of unsurpassable beauty; 'Victory of the Venetians over the Janizaries;' and 'St Sebastian.' In 1530, his friend Aretino (q. v.), the poet, introduced him to the notice of the Emperor Charles V., whose portrait he painted at Bologna, and who gave him several other commissions. From Bologna, T. proceeded to Mantua, where he executed a great number of works for Duke Frederico Gonzaga. In 1532, he appears to have accompanied Charles to Spain, where he remained for three years, and painted several of his masterpieces, now found in that country. In 1537, he executed an 'Annunciation;' in 1541, a 'Descent of the Holy Ghost upon the Apostles,' a 'Sacrifice of Abraham,' 'David and Goliah,' and a 'Death of Abel;' and in 1543, pictures of the 'Virgin' and 'San Tiziano,' and portraits of Pope Paul III., Cardinal Farnese, and Duke Octavio Farnese, at Rome, where he remained three years. The Emperor Charles V., who greatly admired his genius, twice called him to Augsburg (1547 and 1550). Among the religious works which he executed for Philip II. of Spain are a 'Last Supper,' 'Christ in the Garden,' 'St Margaret with the Dragon,' and a 'Martyrdom of San Lorenzo;' besides these, we notice a 'Venus and Adonis,' a 'Danaë,' a 'Medea and Jason,' and other classic subjects. A complete catalogue of T.'s works does not exist, but the number known is extraordinarily great—upwards of 600. T. died of the plague in 1576, having attained the extreme age of 99. He is best studied at Venice or Madrid, but splendid specimens of his work are to be seen in the chief European galleries. As already observed, he had at first a tendency to reproduce the style of acknowledged masters, but his genius soon emancipated itself from all imitativeness, and displayed a glorious originality and power. The luxury of light did never so enrich a painter's canvas. This is, indeed, his transcendent excellence. Not inaccurate in design, not sterile in invention, not infelicitous in composition—these, his minor merits, are nevertheless wholly thrown into the shade by the splendour, boldness, and truth of his colouring, which alone has sufficed to give him a place alongside the greatest names in art, Raphael, Leonardo da Vinci and Michael Angelo.—See Hume's *Notices of the Life and Works of Titian* (Lond. 1829); Northcote's *Life of Titian, with Anecdotes of the Distinguished Persons of his Time* (2 vols., Lond. 1830).

TITICA'CA, LAKE. See PERU.

TITLARK AND TITLING. See PIPIT.

TITLE, REGISTRATION OF, in England, is a modern experiment, set on foot after long-continued opposition, and still frowned on by the solicitors, who conceive that its operation will be to reduce

their emoluments. Owing to the total want which had always existed of a register for deeds or writs connected with the transfer of land, except in the counties of Middlesex and York, the complexity and uncertainty attending the operations of conveyancing had long been the opprobrium of English law, and the mercantile classes at last called for a remedy by which an acre of land might be sold with the same expedition and certainty as bank stock. Under the existing system, so far from expedition being a feature of conveyancing, delay, expense, and insecurity were the chief characteristics. It was and is the inveterate practice for a purchaser of land to demand, and for the vendor to give, what is called a sixty years' title—i. e., he must shew the successive owners of the land for the sixty years previous to the sale, and all that these owners did in connection with it. This created great expense and delay. But if the property were sold next month, or next day, precisely the same process had to be repeated between the new purchaser and his vendor, for what might have been done between other parties previously was not binding, nor was it safely to be acted on by their successors in the property. These evils called loudly for some remedy, and of late years all the legal reformers have been busy with projects to provide some relief. An important impetus was given to a reform by the passing of the Irish Encumbered Estates Act in 1848, the object of which was to break up and compel a sale of the deeply encumbered estates of Ireland. So deeply involved had many of the estates there become, that the nominal owners were merely collectors of the rents for the benefit of others, and all improvements were paralysed. The object of the act was to compel a sale of the fee-simple; and by means of a court specially created for the purpose, called the Encumbered Estates Court, all those who had an interest in the property were summoned to appear and discuss their mutual claims and priorities, and assess, as it were, their pecuniary interest, and the proportion of the total value to which they were entitled; and then the court judicially solved all difficulties, and swept off the property by selling it with a clean title to a purchaser, and dividing the proceeds among all those who claimed a share. The effect was, that a fresh title, free from all prior encumbrances, was given to the purchaser, and thereby the subsequent history of the property was cut off entirely from what had gone before. The court was attended with great success, and subsequent acts perpetuated it as a standing institution of the country, it being found that the clear title thereby obtained was eagerly sought in the market. The court, though at first created for what were supposed to be temporary purposes, has now been called the Landed Estates Court, and its jurisdiction extended not merely to encumbered, but to unencumbered land. In 1854, a similar statute was applied to the estates of the West India Islands, and a court established in London for the purpose of clearing off the encumbrances of those estates, and selling them with a clear title to purchasers. In 1859, a bill was brought into the House of Commons to establish a similar court for England, but owing to the opposition experienced, and to various changes caused thereby, it was not till 1862 that two acts were passed, which provided only an instalment of this much-desired reform. The object of the acts 25 and 26 Vict. c. 53, 67, one of which is called Lord Westbury's, and the other Lord Cranworth's Act, is to enable owners of land to register their estates with indefeasible titles, and to simplify the title by judicial sales effected by the Court of Chancery. The mode of operation is as follows: When a freehold estate is desired to be registered as indefeasible, an application is made to the registrar of the Land Registry, who officially examines the title, and then gives a certificate that the title is indefeasible. Or, if the owner prefer it, he can obtain a similar declaration from the Court of Chancery. Part of the title consists in a map of the lands, which is deposited in the office. The great advantage of getting an indefeasible title from the office is, that the owner is then perfectly certain that he can defy all comers to interfere with his land, and that in the event of his selling it, there is no necessity for the purchaser to re-examine the title, it being stereotyped, as it were, for permanent use, and so all subsequent expenses are avoided. The details attending the scheme of the Land Registry need not be further given. After the statute had been in operation two years, it was found that the progress made by the new institution had been slow; but considering that the adoption of its benefits was voluntary, and not compulsory, and that it was opposed by the solicitors as a body from interested motives, it was stated in parliament that the progress made was satisfactory, and equal to that of other similar reforms which had, after similar early difficulties, taken firm root in the country.

TITLE-DEEDS are the evidences of ownership of real property in this country. Each owner is supposed to be in possession of his own, either by himself or his solicitors; and the ownership of the title-deeds passes along with that of the lands themselves. In England there is no general register where title-deeds can be kept for safe custody; but in the counties of Middlesex and Yorkshire they must be registered. It is a dangerous thing to part with title-deeds, for, by merely pledging them as a security for money, a mortgage may be created over the lands. In Scotland there is a general register where all title-deeds may be kept, or authentic copies, so that the loss of one may be replaced without much difficulty.

TITLES OF HONOUR, designations to which certain persons are legally entitled, in consequence of possessing particular dignities or offices. King and Emperor are titles of honour belonging to the sovereigns of different countries; and Your Majesty is the form of address to which, by the usage of most European countries, they are entitled. Your Grace was in England, in former times, the usual mode of addressing the sovereign. The epithet Majesty, taken from the *majestas* of the emperors of Rome, was adopted by the emperors of Germany, who considered themselves their successors; but its use by other European sovereigns is of comparatively recent date. Henry VIII. was the first king of England, and Henry II. the first king of France, who adopted it. Your Highness is the style adopted by the sultan of Turkey. The proper style of the reigning sovereign of the United Kingdom is, 'Victoria, by the Grace of God, of the United Kingdom of Great Britain and Ireland, Queen, Defender of the Faith.' The sons of the sovereigns of England are styled Princes, and their daughters Princesses; and the sovereign's eldest son is Prince of Wales (q. v.). The title of Royal Highness is given to all the children of the sovereign, and by letters-patent under the Great Seal in February 1864, her Majesty declared her pleasure that the children of the sons of the sovereign should also enjoy the same title. The different grades of the peerage have their several titles—Duke, Marquis, Earl, Viscount, and Baron—each of which was in its origin a name of office involving certain specific duties. See FORMS OF ADDRESS, COURTESY TITLES.

Though most European countries have their dukes, marquises, counts, viscounts, and barons, these often differ considerably in rank from the seemingly corresponding titles in Britain, and the English rules and practices regarding title are not applicable abroad. The complicated system of titles by law, and still more by courtesy, which prevails in England, is a source of endless perplexity to such foreigners as endeavour to make themselves acquainted with our English usages.

TI'TULAR, one who enjoys the bare title of an office, without the actual possession of that office. Thus, the English kings styled themselves kings of France from the time of Henry IV. down to the year 1800; and previous to the recent changes in Italy, the king of Sardinia, as well as the king of Naples, was titular king of Jerusalem. In English Ecclesiastical Law, a titular is a person invested with a title, in virtue of which he holds a benefice, whether he performs its duties or not. —In the law of Scotland, the term has received another acceptation. When the king, at the Reformation, became the proprietor of all church lands, he erected the monasteries and priories into temporal lordships, and bestowed them on laymen, who were known as Lords of Erection, or Titulars; this latter name indicating that they had the same title as had formerly been possessed by the religious houses to the lands and tithes. See TEINDS.

There are many titular dignities in the Roman Catholic Church; but the class of them which is chiefly noticeable is that which has grown out of the separation between the Eastern and Western churches. It is well known that the Roman pontiff, notwithstanding the schism, claims to retain authority over the entire extent of Christendom; and even where there is not any longer resident within the limits of an ancient church or province a body of Christians of the Roman communion, the pope claims to appoint an ecclesiastic to be bishop, metropolitan, primate, or patriarch of the ancient see (see IN PARTIBUS INFIDELIUM). In England, and still more in Ireland, where archbishops and bishops of the Roman Catholic Church exist *de facto*, but not *de jure*, they are styled titular.

TI'TUS, EPISTLE TO, one of the three 'Pastoral Epistles,' was written by St Paul, probably in the latter part of his life, and after he had been liberated from his first imprisonment at Rome. From the 12th verse of chapter iii., we learn that the apostle was staying at Nicopolis when he wrote the letter, and the subscription identifies this place with Nicopolis of Macedonia; but this is impossible, for, as De Wette notices, that city appears to have been founded by the Emperor Trajan long after St Paul was dead. Jerome's opinion is probably the correct one, that the Nicopolis referred to was the famous city in Epirus. The Epistle concerns itself mainly with the organisation and discipline of the church in Crete, is very practical, and at times unpleasantly sharp in its tone, as if Paul had felt more acutely than usual the vexations which 'unruly and vain talkers and deceivers, *specially they of the circumcision*,' caused him. Above all things, however, he is nobly solicitous that the Christians of Crete should prove the sanctifying power of their new faith by rising superior to the immoral practices of heathenism.—See the Commentaries of Chrysostom, Jerome, Aquinas, Luther, Melanchthon, Calvin, Cocceius, Grotius, Rosenmüller, De Wette, Alford, Wordsworth, Ellicott, &c.

TI'TUS FLAVIUS SABINUS VESPASIANUS, emperor of Rome, was the eldest son of Vespasianus (q. v.) and Flavia Domitilla, and was born at Rome 30th December 40 A.D. Brought up at the court of Nero along with Britannicus, the son of the Emperor Claudius, he received an excellent training both of body and mind, became an adept in manly exercises, and an accomplished scholar; and subsequently, as *tribunus militum* in Germany and Britain, and commander of a legion in Judæa under his father, proved his qualities as a soldier and a general. On his father's elevation to the imperial throne, T. was left to prosecute the Jewish war, which he brought to a close by the capture of Jerusalem after a long siege. The news of the success was received with the utmost joy, and Vespasian's too suspicious temper was awakened. However, T., by returning to Rome, and laying the trophies of victory at the emperor's feet, removed his unfounded jealousy, and father and son obtained the honour of a joint triumph (71 A.D.). About this time T. became his father's colleague in the empire, and the impression which the conduct of the young conqueror made upon the Roman people was, and with just reason, very unfavourable. He gave himself up to the pursuit of pleasure in all its forms, put to death various suspected persons very summarily, and even caused one of his guests, whom he justly suspected of conspiracy, to be assassinated as he left the palace. His *liaison* with Berenice, the daughter of Herod Agrippa I. (q. v.), was also very distasteful to the Romans; and on the death of his father (79 A.D.), whom he was at that time believed by a few to have poisoned, the Romans had satisfied themselves as to the advent of a second Nero. But T.'s behaviour after his hand grasped an undivided sceptre completely belied their anticipations. The very first act of his reign was to put a stop to all prosecutions for *læsa majestas*, which had abounded since the time of Tiberius (q. v.); informers were scourged in the forum, dragged along in front of the theatres, and then either sold as slaves or banished. The ancient and venerated buildings of Rome were repaired; new ones, as the Colosseum (see AMPHITHEATRE) and the baths which bear his name, were erected; and the prominent tastes of the populace were abundantly gratified by games on the most stupendous scale, which lasted for 100 days. T.'s beneficence was unbounded, and it so happened that during his brief reign there was the most urgent need of its exercise. In 79 A.D. occurred the great eruption of Vesuvius, which overwhelmed Herculaneum and Pompeii, and ruined numerous other towns and villages; in 80 A.D., a fire broke out in Rome, which raged for three days, destroying the Capitol, Augustus's library, Pompey's theatre, and numerous houses; and in the tracks of these calamities followed a dreadful pestilence. T. dealt out gifts with lavish hand to the houseless and ruined sufferers; he even despoiled his palaces of their valuable ornaments, to obtain money for distribution, and schemed and planned to furnish occupation for them. He was now the idol of his subjects, the 'love and delight of the human race;' but, unfortunately for that part of the human race over which he ruled, in the commencement of the third year of his reign, he became suddenly ill, and died at his patrimonial villa in the Sabine country (September 13, 81), not without the suspicion that he had been poisoned by Domitian, his younger brother.

TIUME'N, a town of West Siberia, in the government of Tobolsk, stands on the Toura, an affluent of the Ob (q. v.). Its advantageous situation on the highways, both by land and water, which communicate between Russia and Siberia, has made it an important commercial centre, and the seat of flourishing manufactures. The vessels which navigate the Ob, the Irtish, the Tobol, and the Toura, for the most part receive their cargoes here. Large

quantities of leather, leather-goods, carpets, soap, candles, and common pottery are manufactured and exported throughout W. Siberia, the Ural countries, the Kirghis Steppes, Khokan, Bokhara, and China. Pop. about 15,000.

TIVERTON, a municipal and parliamentary borough in the north-east of Devonshire, 14 miles north of Exeter. There are important weekly markets, and four great markets for cattle annually. There is a large lace-factory in the town belonging to Messrs Heathcoat & Co., in which upwards of 1000 hands are employed. The town is built on a hill between the rivers Exe and Lowman, hence the old names of the town, TWYFORD and TWOFORD-TOWN. The streets in many places are very narrow, but clean. There is a peculiarity about the town in the rapid streams of water flowing down the channels along the sides of the streets. These streams of water were given to the town about the year 1272, by Isabella Rivers, Countess of Devon. The castle was built in 1106. The free grammar-school, an old building in the Elizabethan style, was endowed by Mr Peter Blundell in 1604. In connection with the school there is a scholarship at Balliol College, Oxford, and another at Sydney Sussex College, Cambridge, each of the annual value of not less than £60. There are four exhibitions, of £30 per annum each, for four years, at any college in either university; one exhibition of £50 a year, for seven years, at Balliol College; and one of £25. There are other schools and numerous charities. T. sends two members to the House of Commons. Pop. (1871) 10,025; (1881) 10,462.

TIVOLI (anc. *Tibur*), a poor town of the comarca or province of Rome, 18 miles east from Rome, stands on the slope of Monte Ripoli, one of the Apennines. T. is walled, and has a fortress. The streets are steep, narrow, and beset by beggars. There is a fine cathedral, formerly a temple of Hercules, where Augustus held his tribunal. The surrounding hills are covered with olive trees. The vines of T. are famed for a peculiar sort of grape, in great request for its firmness and luscious flavour, noticed as early as the time of Pliny the Elder. The stone called 'travertino,' of which great part of Rome is built, comes from Tivoli. Pop. 6400. Near T. is the extensive Villa d'Este. Within and without the city, there are many monuments of antiquity. In a commanding position above the falls of the Anio, rises the Temple of Vesta, of a circular form, and in good preservation, built 70 B.C.; there are the extensive remains of the Emperor Hadrian's magnificent villa; the villa of Mæcenas; remains of mausoleums, aqueducts, baths, &c. The place is much visited by tourists for its waterfalls, which are lofty, but not very picturesque.

Tibur long existed as a town (according to ancient tradition) before the building of Rome; but the first mention of it in recorded history occurs 446 B.C., during the Roman decemvirate. It was one of the principal towns of the Latin confederation. Its healthy and picturesque situation induced many of the wealthy Romans to choose it for their country residences. Mæcenas, Scipio, Æmilianus, the famous Marius, Metellus Numidicus, and Munatius Plancus, had their Tiburtine villas. Horace preferred Tibur to all other places of resort (although he makes allusion to its moist atmosphere, calling it 'Udum Tibur'), and had a country-house in the neighbourhood. It is one of the few towns of Latium which still stand on their ancient sites.

TLEMCEN', a town of Algeria, capital of the province of Oran, and 80 miles south-west of the city of that name, stands in an undulating country, everywhere irrigated, and brought completely under cultivation. It contains Catholic and Protestant churches, mosques, and synagogues, and there are numerous educational institutions, including schools for Arabs and Jews. It is protected from the south wind by a range of hills, 4200 feet in height. The town is accessible only from the south-west, the other sides presenting steeply escarped fronts. The district around T. is covered with fruit-trees of all kinds, of which the olive is one of the most valuable, and there is much cultivated land, producing cereals, tobacco, &c. Besides the special markets, a daily market is held, at which cattle, wool, grain, and oils are largely sold. Ostrich feathers and corks are exported; but the trade is for the most part in cloths, hides, grain, and oils. Pop. about 20,000.

TOAD (*Bufo*), a genus of *Batrachia*, of the *Anourous* or tailless order, and suborder of *Arcifera Bufoniformia*. See BATRACHIA. The original genus has been subdivided, and is now constituted into a family, *Bufonidæ*, to all which the popular name T. is often extended. The form resembles that of the frogs, but is more thick and clumsy, and the hind-legs are generally short, so that the species rather crawl than leap; some of them, indeed, are not known to leap at all. The skin is warty, and the warts or tubercles produce a milky exudation, which in some species is very fetid. Behind the ear there is a porous pad—a very large parotid gland—from which a copious exudation takes place. The muzzle in the restricted genus *Bufo* is rounded, but some of the family have an elongated muzzle. The mouth of the true toads is destitute of teeth. The food of toads consists chiefly of small insects and slugs, and they mostly inhabit shady places, avoiding the sunshine, and crawling about either amongst the stems and leaves of plants or amongst stones. In their adult state, they are much less aquatic than frogs, but their spawn is deposited in water, in which their tadpoles live like those of frogs. They are commonly regarded with disgust, on account of their appearance, the exudation from the skin, and the smell of many of them, yet the eye of the T. is remarkably beautiful. A notion has very generally prevailed that the exudation of the skin is venomous, but it is unsupported by evidence, and toads are handled with perfect impunity. They are eaten by some savage tribes.—Only two species are British. The COMMON T. (*B. Americanus*) is abundant in most parts of North America. A description of it is unnecessary. It spends the winter in a dormant state, and issues from its retreat on the return of spring. Its spawn is deposited in March or April, and resembles that of the frog, but the ova are smaller and more numerous, and are discharged in a long albuminous tube, which is coiled spirally in the water. The young T. is very small when it loses its tail and gills and exchanges the tadpole for the adult form. Toads are very useful in gardens, in preventing the excessive increase of some kinds of insects; and on this account, it is a frequent practice to put them into hot-bed frames, for which use the market-gardeners of the neighbourhood of London often purchase the European species at the price of fourpence each. They have occasionally been tamed, and display some intelligence, readily recognising those who feed them and are kind to them. A tame T., of which an account is given by Pennant in his *British Zoology*, lived for more than forty years, and was at last killed by a raven.

Numerous instances are on record in which toads are said to have been found embedded in rocks, walls, and even in the trunks of trees, where the necessary conclusion is that they must have lived a very long time, in a dormant state. Unfortunately, however, the discovery of these toads has almost always been made by unscientific

persons, and there is a want of proper and trustworthy observations as to the places in which they have been found. Attempts have been made by several naturalists, and among others by the late Dr Buckland, to throw light on the subject by experiment, immuring toads in various ways, and the result, although shewing that when air is not wholly excluded, they are capable of living for a long time in their imprisonment, probably in a dormant state, is not favourable to the belief that such existence could extend over many years. An interesting account of Dr Buckland's experiments will be found in Mr F. Buckland's *Curiosities of Natural History.*

The other British species of T. is the NATTERJACK (*Epidalea calamita*), which was first described as British by Pennant, and has since been found to

1, Common Toad (*Bufo vulgaris*); 2, Natterjack (*Epidalea calamita*).

be pretty abundant in some parts of England, and in the south-west of Ireland, chiefly in the vicinity of the sea. It much resembles the common T., but is of a yellowish-brown colour, clouded with dull olive, a bright yellow line passing along the middle of the back. It has a disgusting smell. It never hops, and its motion is more like walking or running than the crawling of the common toad.—Several other species of T. are found in Europe. Some of those found in tropical countries attain a very large size, and exhibit protuberances of various kinds, far exceeding even in proportion the warty excrescences of the common toad.

TOADFLAX (*Linaria*), a genus of plants of the natural order *Scrophularineæ*, very closely allied to SNAPDRAGON (q. v.), from which genus this has but recently been separated, and is distinguished chiefly by the spur at the base of the corolla, and the capsule opening by valves or teeth, not by pores.—The species are herbaceous plants, natives chiefly of the colder and temperate parts of the Old World. Some of them are natives of Britain, of which the most common is *L. vulgaris*, a species with erect stem of 1—3 feet high, glaucous linear-lanceolate leaves which thickly cover the stem, and terminal spikes of yellow flowers. It grows in hedges, the borders of cornfields, &c. It possesses purgative and diuretic properties, and a decoction of it is used as a fly-poison; but it is regarded as a troublesome weed by farmers. It has found its way, probably along with grain or other grass seeds, into the United States. A very remarkable monstrosity is sometimes seen in this plant, to which the name *Peloria* has been given, the flower presenting five spurs, and five usually imperfect stamens.—*L. Cymbalaria*, a pretty little plant with trailing stems and 5-lobed cordate leaves, is often planted to cover old walls, &c., and is either a native of Britain, or naturalised in many places.

TOADSTONE, a local Derbyshire name for a soft and earthy variety of trap, looking like an argillaceous deposit.

TOAST (Lat. *tostus*, scorched or roasted) is the name given to bread dried or scorched before the fire. So early as the 16th c., toasted bread formed a favourite addition to English drinks. Sack was drunk with toast, and so was punch. The practice of drinking healths, particularly that of an entertainer, is one so natural, so likely to spring up spontaneously, that it is impossible to say when it began. Certain it is, however, that it received an artificial development owing to the prevalence of convivial habits in the 17th century. Then it became the fashion to drink not to the health of entertainers only, but to that of each guest, of absent friends, and more especially of the unmarried woman whose attractions were most generally acknowledged. It also became the custom to describe a woman whose health was so drunk as herself 'a toast.' In this sense, the application of the word is said to have had its origin in an incident which occurred at Bath, and which is recorded in the 24th number of the *Rambler*, in the following passage: 'It happened that on a public day, a celebrated beauty of these times' (when it was the fashion for ladies to bathe publicly in elegant dresses made for the purpose) 'was in the Cross Bath, and one of the crowd of her admirers took a glass of the water in which the fair one stood, and drank her health to the company. There was in the place a gay fellow, half fuddled, who offered to jump in, and swore, though he liked not the liquor, he would have the toast' (making, of course, allusion to the custom of putting toast in punch). 'He was opposed in his resolution; yet this whim gave foundation to the present honour which is done to the lady we mention in our liquor, who has ever since been called a toast.' Whatever may be the origin of the use of the word 'toast' in this sense, we now apply it not only to any person, but to any sentiment mentioned with honour before drinking. The French have adopted the word 'toast' from us; making it masculine when applied to a man or a sentiment, but feminine when applied to a woman. —See Chambers's *Book of Days.*

TOBA'CCO (of uncertain derivation, but most probably from the native American name), a genus (*Nicotiana*) of plants of the natural order *Solanaceæ*, having large broad leaves; a 5-parted calyx; a funnel-shaped, 5-lobed corolla, and five stamens; the flowers growing in panicles at the top of the stem; the fruit a 2-celled, 5-valved, many-seeded capsule. The species are mostly herbaceous plants, rarely shrubby, with large broad leaves, and everywhere covered with clammy hairs. They are natives of warm countries, most of them American, although some are found in the East Indies. They all possess the narcotic property, on account of which a few of them are extensively cultivated. It resides in almost all parts of the plant, although the leaves are almost exclusively used. The most important species is the COMMON T. or VIRGINIAN T. (*N. tabacum*), a native of the warm parts of America, the cultivation of which had extended before the discovery of the New World

by Columbus, far to the north of the regions in which the plant appears to be indigenous. It is about 5 or 6 feet high, erect, with lanceolate, sessile leaves, 6—18 inches long, and rose-coloured flowers, the throat of the corolla inflated, the segments pointed. There are numerous varieties, differing more or less in the size and form of the leaves, and in the form and colour of the flowers, some of which are regarded by some botanists as distinct species.

Virginian Tobacco (*Nicotiana tabacum*).

Green Tobacco (*Nicotiana rustica*).

One of these is the BROAD-LEAVED T., or MARYLAND T., which has a thicker stem, and much broader leaves. The GREEN T. (*N. rustica*), sometimes called ENGLISH T., because it was the first kind introduced into England for cultivation, is a smaller plant, from 3 to 5 feet high, with ovate, stalked leaves, and the segments of the corolla rounded, its tube cylindrical. It is a native of the East, but is more hardy than the Virginian T., and is therefore cultivated in more northern regions. The PERSIAN T. (*N. Persica*) has the root-leaves oblong, those of the stem lanceolate and sessile; the corolla salver-shaped, with a long tube; its lobes rather unequal. It is a native of Persia, and furnishes the Shiraz T., so much esteemed in the East, and which is milder than the common tobacco. Other species of T. are used in different parts of America, and some of them are cultivated to a small extent, as *N. repanda*, in Cuba; *N. quadrivalvis*, by the Indians on the Missouri; *N. multivalvis*, by the Indians on the Columbia; and *N. nana*, by the Indians of the Rocky Mountains.

It is somewhat doubtful whether the use of T. as a narcotic was known in the East before the discovery of America. Meyen, in his *Geography of Plants*, expresses the opinion that the smoking of T. is of great antiquity amongst the Chinese, because on very old sculptures he has 'observed the very same tobacco-pipes which are now in use.' Meyen's authority, however, is greater as a botanist than as an archæologist, and cannot be received as decisive of the antiquity of the sculptures of which he speaks. It is not improbable that the smoking of T. has been long practised in China, but it is not certain. If it was so, the custom did not extend amongst neighbouring nations, which, however, has been the case also as to the use of some other narcotics; whereas, on the introduction of the use of T. from America, it rapidly extended throughout Europe, and soon became extremely prevalent amongst Oriental nations. In the present state of our knowledge, no ethnological argument can be founded upon the prevalence of smoking amongst the Mongolians and the American Indians. The smoking of T. was found by Columbus to be practised in the West Indies, where the natives made it into cylindrical rolls, wrapped in maize-leaf. It has been prevalent from unknown antiquity amongst the American Indians as far north as Canada. With them it even has a religious character, and is connected with their worship and with all their important transactions. Thus, the Calumet (q. v.), or pipe of peace, is indispensable to the ratification of a treaty, and smoking together has even greater significance of friendship than eating together has amongst other nations. 'In the belief of the ancient worshippers, the Great Spirit smelled a sweet savour as the smoke of the sacred plant ascended to the heavens; and the homely implement of modern luxury was in their hands a sacred censer, from which the hallowed vapour rose with as fitting propitiatory odours as that which perfumes the awful precincts of the cathedral altar, amid the mysteries of the church's high and holy days.'—Wilson's *Prehistoric Man*, i. 383. The seeds of the T. plant were first brought to Europe by Gonzalo Hernandez de Oviedo, who introduced it into Spain, where it was first cultivated as an ornamental plant, till Nicolo Menardes extolled it as possessed of medicinal virtues. It was introduced into Italy in 1560. The use of T. in the form of snuff soon followed its introduction for smoking. There is no reference to the use of T. in Shakspeare, yet it is certain from other evidence that it was well known in England in his time, although at first its use was confined to the wealthy, as the price was very high, and it was smoked in very small pipes—probably the same which are known to antiquaries as *Elfin Pipes*—and the smoke was expelled, not from the mouth, but by the nostrils, in which way the narcotic power of the herb is much greater. T. was at first recommended for medicinal virtues, which were greatly exaggerated, but soon became an article of luxury. The popes Urban VIII. and Innocent XI. fulminated against it the thunders of the church; the priests and sultans of Turkey declared smoking a crime, Sultan Amuret IV. decreeing its punishment by the most cruel kinds of death; the pipes of smokers were thrust through their noses in Turkey; and in Russia, the noses of smokers were cut off in the earlier part of the 17th century. King James I. of England issued a *Counterblaste to Tobacco*, in which he described its use as 'a custom loathsome to the eye, hateful to the nose, harmful to the brain, dangerous to the lungs, and in the black, stinking fume thereof nearest resembling the horrible Stygian smoke of the pit that is bottomless.' All opposition, however, was in vain. The use of T. increased, and has continued to increase to the present day, when it is more prevalent than at any former time, the luxury of rich and poor, of civilised nations and of savage tribes. Although it did not become prevalent in the East till the 17th c., the Turks and Persians are now the greatest smokers in the world; in India, all classes and both sexes smoke; in China, the practice—perhaps there more ancient—is universal, and girls, from the age of eight or nine, wear, as an appendage to their dress, a small silken pocket to hold tobacco and a pipe. How the practice of smoking has increased in Britain, every one knows. The use of snuff has not increased

in the same manner, but has rather diminished. T. is used in the three modes of smoking, chewing, and snuffing. Plugging, the stuffing of the nostrils with quids of T., has been almost universally discontinued, although at one time it was practised to a small extent. In Britain, chewing is now chiefly practised by sailors, smoking being prohibited or restricted at sea, on account of the danger of fire; but it is very prevalent in some parts of the world, particularly in North America. The smoking of T. is everywhere more or less social, like the use of wine; and the snuff-box is handed from one to another in token of good-fellowship.

T. derives its botanical name (*Nicotiana*) from Jean Nicot, who introduced it into France. In that country, its use in the form of snuff began in the reign of Francis II. About the same time, a snuff-manufactory was established at Seville, which produced the celebrated Spanish snuff. The T. plant was soon after introduced into other countries of Europe. In 1657, the manufacture and sale of T. were farmed out in Venice, and began to yield a considerable revenue. Much revenue has since been derived from the same source, in many countries. T. is now extensively cultivated in many parts of Europe, as well as in Asia and America. Prohibitory laws alone prevent its cultivation in the southern parts of Britain and Ireland, of which the climate is quite suitable to it. The quality of the leaf, however, deteriorates in the more northern regions in which it is cultivated, as in Germany, when it is continuously raised from home-grown seed, and seed is therefore imported from warmer countries.

Cultivation and Commerce.—The cultivation of T. requires a rich loose soil, and the strongest manures are advantageous. The influence of soil, climate, and manures on the quality of the produce is very great, almost beyond what is known in any other cultivated plant. Vegetable manures are best for T. intended for smoking; animal manures are preferred for that which is to be made into snuff. In the more northern regions in which T. is cultivated, the seed is sown in a hot-bed, protected from frost by mats, and the plants are planted out in rows from two feet to three feet apart in the field. The ground is frequently hoed and stirred. Where the plants are not intended for seed, the top is usually broken off, so as to prevent flowering, that its whole strength may be directed to the leaves. In America, when the leaves begin to become yellow, or are marked with yellow blotches, the plants are cut down, and hung up in a large barn to dry; but in Germany, the leaves are gathered as they become yellow, are tied in small bunches, and are hung up in a shady place to dry.

The cultivation of T. is comparatively easy, and although a warm climate suits it best, it is without much difficulty raised in most parts of Europe. The usual plan in the great tobacco-producing countries is to sow the seed in seed-beds of rich soil, and as the seed is extremely minute, it is first mixed largely with sand or wood-ashes, to assist in spreading it thinly. In Virginia, which may be taken as one of the best tobacco-growing districts, this is usually done in the first week in January. After the seed-beds have been carefully prepared and sown, small branches of trees are laid over, to protect the seed, when it germinates, from the effects of frost; but these are removed as soon as can be done with safety, and the plants then grow rapidly, and are ready for transplanting into the fields about the beginning of June. The land in the fields is very carefully prepared, and small hillocks are raised up in rows; each is about a foot in diameter, and flattened at the top. With the first appearance of rain, the plants are carefully raised from the seed-beds, and carried usually by children, who deposit one on each hillock, on which it is carefully planted by experienced men, who follow after the children. Only wet weather will do for planting, so that this operation often lasts until the end of July. When planted, the tobacco-crop requires much careful attention, to weeding, and a watchful eye to prevent the ravages of various insect enemies. Much of this latter work is done by flocks of turkeys, kept on purpose by the planters. As soon as the plants begin to throw up the flower-shoot, it is nipped off; otherwise it would weaken the leaves; but this process is neglected in some countries, especially in Turkey and Greece, where small leaves are preferred, and where, in some cases, as in the celebrated Latakia tobacco, both leaves, buds, and flowers are used. The time generally chosen for cutting it is mid-day, or when the sun is powerful, and the morning and evening dews absent. The cutting is done by hand, and only such plants are chosen as are ready, which is known by a clammy exudation which forms over the leaf, often giving it a spotted appearance. If the plants are very large, the stalk is often split down, to facilitate the drying. They are then removed from the field to the tobacco-house, around which are erected light scaffolds, to which the plants are suspended, generally by passing a thin stick through a split in the stalk of each, and so placing a number of plants on each stick, just near enough to prevent them touching each other. After some time hanging in the open air, the plants on the sticks are removed, and suspended in a similar way inside the curing-house, until the drying is completed. The leaves are next removed from the stalks, and all bad ones rejected. The chosen ones are tied up in bundles called hands, and these are packed in hogsheads, enormous pressure being applied in the packing. These hogsheads are very large casks, which must not contain less than 950 lbs. net in the United States, where the government exercises a very strict surveillance over the weight and quality of all tobacco grown and cured there. Within the last ten years, a large tobacco-export has been carried on by Paraguay. The quality, though not equal to that grown in the United States, is, however, fair, and has been steadily improving. It is always packed in linen bales. Turkey has also, for several years past, been steadily increasing her exports of tobacco to Great Britain. The quality of Turkish tobacco is very peculiar: it is small in the leaf, and of a light colour—either a bright yellow, a yellowish green, or a yellowish brown. Being extremely mild, it is a favourite with many smokers.

Tobacco, owing to the high rate of duty when in any manufactured form, is mostly imported in the leaf; but small quantities are brought in, chiefly for re-export, in various states of manufacture. The chief of these is called Cavendish, which is made by stripping the blades of the leaves from the midribs, and after sprinkling them with an infusion of tobacco made from the stalks and other waste parts, laying them in heaps to heat or ferment. This darkens their colour; and whilst still moist and flaccid, they are laid smoothly upon each other, so as to form cakes about nine inches in length by three in breadth, which are pressed by powerful machinery until they are very compact and hard. Another kind is called Negrohead, which is formed into sticks about an inch thick, and eight or nine in length, which are laid across each other equally, and are then pressed into cakes. When the sticks are pulled apart, the rounded depressions caused by pressing them into one another gives them a slight resemblance to the wavy locks of a negro's hair, whence they receive

their name. The leaf simply twisted into a rope, as in the kind called Varinas Roll and other similar sorts, as well as that which is merely cut small for smoking, is all held to be 'manufactured,' and charged with the highest duty, so that very little indeed is imported.

Cigars and *Cheroots* are also forms of manufactured tobacco; but so much in favour are these with smokers, that the exorbitant duty is very little check upon their importation. The island of Cuba supplies not only the best but also the largest quantity, the Havana tobacco being exceedingly well cultivated and cared for, and being especially well adapted for cigar-making. More than half of all the cigars imported into Great Britain are from Cuba; and the cheroots are chiefly from Manilla. The Philippine Islands also send us about 100,000 lbs. per annum of cigars, and other countries about 200,000 lbs. The total amount sent to Great Britain annually is a little over 600,000 lbs., equal in value to about £350,000. Cigars and cheroots are essentially the

Cigar.

Cheroot.

same; they only differ in form, as represented in the diagrams.

The tobacco received in the leaf is all more or less manufactured in this country. It is either cut finely, so as to be convenient for use in pipes, or made into Cavendish, Negrohead, or Twist; the last is often called *Pig-tail;* and is a continuous string of tobacco about the thickness of a quill, many yards in length, made by twisting and spinning the leaves when flaccid from being wetted and heated as before described; this string is then made up into balls, and is the kind chiefly used by those who chew tobacco.

Snuff is another form of manufactured tobacco largely made in Great Britain. It is formed by grinding the leaf either with or without the leaf-stalks and midribs. The grinding is generally effected in wooden mortars, with pestles also of wood; and some kinds of snuff are prepared from kiln-dried tobacco, whilst others are made from the soft leaves. The varieties are numerous, and fortunes have been made by manufacturers who have been fortunate enough to make a snuff which has become a favourite.

Tobacco is subject to a higher rate of duty, in proportion to its intrinsic value, than any other article. The value of the best sorts in the leaf only ranges from 3*d.* to 9*d.* per pound; whilst the duty is as follows: Unmanufactured, containing 10 per cent. or more of natural moisture, 3*s.* per pound; and if containing less than 10 per cent. of moisture, 3*s.* 6*d.* per pound. The various kinds of manufactured tobacco range from 3*s.* 9*d.* to 5*s.* per pound. The chief regulations touching its importation are as follow: It is prohibited to be imported at any other ports in the United Kingdom than Aberdeen, Belfast, Cork, Cowes, Drogheda, Dublin, Falmouth, Fleetwood, Galway, Glasgow, Greenock, Hartlepool, Hull, Lancaster, Leith, Limerick, Liverpool, London, Londonderry, Newcastle, Newry, Plymouth, Port-Glasgow, Portsmouth, Preston, Sligo, Southampton, Swansea, Waterford, Wexford, and Whitehaven: or in original packages of less than 80 pounds weight. Passengers, however, may pay duty on any quantity of manufactured tobacco or cigars under 3 pounds, if from the continent, and any quantity not exceeding 7 pounds if from the East and West Indies, and other distant voyages; and of manufactured tobacco, passengers may pay duty, and import as surplus stores any quantity not exceeding 9 pounds. Of cigars unconsumed on the passage, the passenger is only allowed 8 ounces free of duty. The penalties for any evasion of these regulations are very heavy.

In the United States the tobacco-culture enters largely into the agricultural industry—the annual amount raised being about 270,000,000 pounds. According to the census returns of 1870, the yield in several of the principal tobacco-growing states was as follows, in pounds: Alabama, 152,742; Arkansas, 594,886; California, 63,809; Connecticut, 8,328,798; Florida, 157,405; Georgia, 288,596; Illinois, 5,249,274; Indiana, 9,325,392; Iowa, 71,792; Kansas, 33,241; Kentucky, 105,305,869; Maryland, 15,785,339; Massachusetts, 7,312,885; Mississippi, 61,012; Missouri, 12,320,483; New Hampshire, 155,344; New Jersey, 40,871; New York, 2,349,798; North Carolina, 11,150,087; Ohio, 18,741,973; Pennsylvania, 3,467,539; South Carolina, 34,805; Tennessee, 21,465,452; Texas, 59,706; Vermont, 72,671; Virginia, 37,086,364; West Virginia, 2,046,452; Wisconsin, 760,813.

Under the existing United States revenue laws the duties upon cigars, cigarettes, and cheroots are $2 50 per lb., and an additional internal revenue tax upon cigars and cheroots of $5 per thousand. Cigarettes weighing over 3 lbs. per thousand have a tax of $5 per thousand; under 3 lbs. per thousand, the tax is $1 50.

Other manufactured tobaccos are subject to 50 cents per lb. duties and an internal revenue tax of 20 cents per lb. The duty on unmanufactured tobacco in leaf is 35 cents per lb.; stems, 15 cents per lb.

Tobacco-leaves, when submitted to chemical analysis, yield Nicotine (q. v.), which is its most characteristic constituent, albumen, a gluten-like substance, gum, resin, malic and citric acids, and a large amount of inorganic constituents, 100 parts of the dry leaf yielding from about 19 to 27 per cent. of ash, in which potash, lime, and silica preponderate. In a physiological and medical point of view, the analysis of the smoke of tobacco is of far more importance than that of the leaf. From the researches of Dr Richardson, it appears that although 'the widest differences prevail in respect to the products arising from differing cigars, differing kinds of tobacco, and differing pipes,' there are certain substances which are common to all varieties of tobacco-smoke. Firstly, there is in all tobacco-smoke a certain amount of *watery vapour*, impregnated with various substances, from which it may be separated. Secondly, a small quantity of free *carbon* is always present; it is to the presence of this constituent that the blue colour of the smoke is due. 'It is this carbon,' says Dr Richardson, 'which in confirmed and inveterate smokers settles on the back part of the throat and on the lining membrane of the bronchial tubes, creating often a copious secretion, which it discolours, and which is coughed up of a dark coaly appearance.'—*For and Against Tobacco*, Lond. 1865, p. 5. Thirdly, there is a certain quantity of *ammonia* present. The presence of the ammonia gives to the smoke an alkaline reaction. Moreover, 'it is the ammonia that bites the tongue after long smoking; it is the ammonia that makes the tongue and throat of the smoker so dry, and induces him to quaff as he smokes, and that partly excites the salivary glands to secrete so freely. The ammonia also exerts an influence on the blood.'—Richardson, *op. cit.*, p. 6. Fourthly, *carbonic acid* is always present, as may be shewn by its action on lime-water. The amount differs extremely in the smoke from different kinds of tobacco, but, according to Dr Richardson, it may be fairly inferred that the sleepiness, headache

and lassitude which follow the prolonged inhalation of tobacco-fumes, are largely due to this agent. Fifthly, tobacco-smoke yields a *product having an oily appearance*, and possessing poisonous properties. It is popularly known as *oil of tobacco;* and on further analysis, it is found to contain three substances—viz., a fluid alkaloid, *nicotine;* a *volatile substance* having an empyreumatic odour; and an *extract* of a dark resinous character, having a bitter taste. The symptoms of tremor, palpitation, and paralysis which ensue after excessive smoking, especially in persons unaccustomed to indulgence in this practice, seem to depend upon the nicotine, which is known, by experiment, to be highly poisonous. 'The peculiar smell of stale tobacco-smoke, which hangs so long on the breath of the smoker, and on articles of clothing, is derived from the volatile empyreumatic substance; and the exceedingly nauseous sharp taste which is recognised by every unpractised smoker, when he takes a foul pipe into his mouth, is due to the bitter extract. It is apparently this extract which creates vomiting in persons unaccustomed to tobacco, and of which the body after a time becomes tolerant.'—Richardson, *op. cit.*, p. 8. Hence it appears that the more common effects are due to the carbonic acid and the ammonia; while the rarer and more severe are due to the nicotine, the empyreumatic substance, and the resin.

It is unnecessary to enter into details regarding the symptoms of slight tobacco-poisoning, because they are well known to the great majority of the male population. Fortunately, the effects produced by tobacco are very transitory, as the poison finds a ready exit from the body. The system, after being subjected for a few times to the poisons of tobacco-smoke, becomes accustomed to their influence, the distressing symptoms no longer occur, and a condition of 'tolerance' is established. From the extensive investigations of Dr Richardson, it appears that there are no grounds for believing that smoking can produce any organic changes. It may, however, produce various functional disturbances: (*a*) On the stomach. (*b*) On the heart, producing debility and irregular action. (*c*) On the organs of the senses, as dilatation of the pupil, confusion of vision, subjective sounds, &c. (*d*) On the brain, suspending the waste of that organ, and oppressing it if it be duly nourished, but soothing it if it be exhausted. (*e*) On the nerves, leading to over-secretion of the glands which they control. (*f*) On the mucous membrane of the mouth, causing what has been described as the 'smoker's sore throat.' 'The disease consists of an irritable state of the mucous membrane at the back of the throat, redness there, dryness, a tendency to cough, and an enlarged soft, sore condition of the tonsils, rendering every act of swallowing painful and difficult.' It may exist without detection for a long time; but if a damp, cold, foggy state of the air comes on, the throat becomes troublesome and painful, enlargement of the tonsils is detected, and the symptoms become much aggravated by any attempt to smoke. This condition is more readily induced by the use of cigars than of pipes; it is quite incurable so long as the patient continues to smoke, but soon disappears when the use of tobacco is entirely suspended. In association with this condition of the throat, the gums are usually abnormally pale and firm. (*g*) On the bronchial surface of the lungs, sustaining any irritation that may be present, and increasing the cough. There is no evidence that tobacco-smoke can cause specific diseases, such as insanity, epilepsy, St Vitus's dance, apoplexy, organic disease of the heart, cancer, consumption, or chronic bronchitis. If, as is universally allowed, tobacco possesses, like alcohol, arsenic (in minute doses), opium, tea, coffee, &c., the power of arresting the oxidation of the living tissues, and thus checking their disintegration, it follows (1) that the habit of smoking must be 'most deleterious to the young, causing in them impairment of growth, premature manhood, and physical degradation' (Richardson, *op. cit.*, p. 73); and (2) that the habit may be conducive to the physical well-being of the individual, provided he cannot supply himself with sufficient nourishing food to supply the daily tear and wear of the muscular and nervous systems.

For a long controversy on the question, *Is Smoking Injurious to Health?* in which Sir Ranald Martin, Mr Solly, Dr Ranking, and other medical men took a part, the reader is referred to the 1st volume of *The Lancet* for 1857. The whole matter is very fairly summed up by Dr Richardson in the excellent pamphlet from which we have so freely borrowed in this article—a memoir which we can cordially recommend to all who take an interest in this subject. Before the full maturity of the system is attained, even the smallest amount of smoking is hurtful; subsequently, the habit is, in most instances, only prejudicial when it is carried to excess. We cannot honestly say more against tobacco than can be urged against any other luxury, and of nearly every luxury it is the least injurious. 'It is innocuous as compared with alcohol; it does infinitely less harm than opium; it is in no sense worse than tea; and by the side of high living altogether, it contrasts most favourably.'—Richardson, *op. cit.*, p. 75. In conclusion, a word or two may be said regarding the kind of pipe that should be used. A long, perfectly clean pipe, composed of an absorbing material like clay or meerschaum, which can suck up the oily matter before it reaches the mouth, is always to be preferred; and M. Melsens, to whom the scientific world is indebted for many ingenious applications of chemistry to hygiene and the treatment of diseases, has recently suggested, that if a plug of cotton, saturated with a strong solution of citric or tannic acid, were placed in the stem, so as to filter the smoke before it reached the mouth, all the nicotine would be seized by and combine with the acid. The different kinds of tobacco exert a different influence on the smoker according to the amount of noxious ingredients which they contain. Thus, cavendish, pigtail, and coarse shag yield the oily matters in much more abundance than Latakia or Turkish, which are hence termed mild tobaccos. Cigars produce dyspepsia much more rapidly than pipes, for in smoking them, unless with a long mouth-piece, nicotine is necessarily absorbed.

Snuffing is probably the least injurious form in which to take tobacco, and chewing the most deleterious; yet sailors, who chew more freely than any other class in this country, are usually men in vigorous health, and after prolonged practice, the quantity they can consume is enormous. Dr Arrott mentions the case of a harbour-superintendent, formerly a sailor, aged 64, in the almost uninterrupted enjoyment of good health, who has chewed tobacco for upwards of 50 years, and now also *eats* it, swallowing every particle of leaf and juice. For many years, he has been in the constant practice of 'eating a quarter of a pound of the strongest negrohead every five days.'—*The Lancet*, 1847, vol. i. p. 440.

The effects which tobacco produces in large doses, when taken by persons unaccustomed to its use, in the form of powder, infusion, or excessive smoking, are 'faintness, nausea, vomiting, giddiness, delirium, loss of power of the limbs, general relaxation of the

muscular system, trembling, complete prostration of strength, coldness of the surface, with cold, clammy perspiration, convulsive movements, paralysis, and death. In some cases, there is purging, with violent pain in the abdomen; in others, there is rather a sense of sinking or depression in the region of the heart, creating a sense of impending dissolution. With the above-mentioned symptoms, there is a dilatation of the pupils, dimness of the sight, a small, weak, and scarcely perceptible pulse, and difficulty of breathing.'—Taylor's *Principles and Practice of Medical Jurisprudence*, p. 321. Although there are two recorded cases of poisoning by nicotine, poisoning by tobacco has rarely given rise to medico-legal investigation. There is, however, reason to believe that porter is often drugged with tobacco or Scotch snuff, for the purpose of stupefying persons with a view to robbery. In all cases of poisoning with tobacco, if it has been swallowed, an emetic of a scruple of sulphate of zinc should be at once administered, and the most powerful stimulants, both external and internal, should be employed. Professor Haughton has shewn that nicotine and strychnine antagonise one another; on this assumption, strychnine, carefully administered, would be the proper antidote.

Tobacco has been used in medicine in the form of an enema, with the view of relaxing the muscular fibres, in cases of strangulated hernia, stricture of the bowel or urethra, tetanus, &c.; but in such cases, it has now been generally superseded by chloroform. If it continue to hold a place in the Pharmacopœia, it will probably be as an antidote to strychnine.

It must be recollected that *Indian Tobacco* has nothing in common with the subject of this article, and is a synonym for *Lobelia inflata*.

TOBACCO-PIPES are made of various materials, the commonest in Europe being a fine white clay, which has consequently received the name of *pipe-clay*. Their usual form is too well known to need description, but the manufacture of a clay tobacco-pipe is by no means a simple affair. The first part of the operation is performed by trained children, who, with nice skill, roll out upon a board a small piece of clay into a long slender cylindrical rod, at the end of which is then attached a lump of clay, just enough to form the bowl. These rudimentary pipes are arranged by dozens on a board, until they have become sufficiently hardened. They are then handed to the pipe-maker, who takes a pointed iron wire, and first dipping it into oil, pushes it into the end of the thin column of clay, and having passed it through, forms the bowl with a folding brass mould. The wire is then withdrawn; and after a slight dressing with a knife, the pipes, now complete, are slightly curved in the stem, and are laid by to dry for a few days, when they are removed to the kiln, which is of a peculiar construction, and consists of an interior chamber, with a number of small stages, so that the pipes can be conveniently arranged in circles without touching each other. This interior chamber can be closed so as to exclude smoke, and, in fact, is only a *seggar* on a large scale, such as is used in making Pottery (q. v.). The fire acts all round it, and fires or burns the pipes without smoking them. When thoroughly baked, they undergo a kind of polishing or dressing, and are fit for sale. Finer and more expensive pipes are made of Meerschaum (q. v.). Under the head of PIPE-STICKS will be found an account of the various materials used for making the tubes of these and other pipe-bowls. *Brier-root pipes*, now very common, have the bowl and stem made of one piece of wood; and although the stem is short, they partially absorb the oil produced in smoking, which, however, is perhaps as much the case with the common clay-pipe when it is new.

Various opinions have been entertained as to the antiquity of the practice of smoking, and consequently of the use of pipes. That pipes for smoking herbs for medicinal and other purposes were in use in England and elsewhere long before the introduction of tobacco, is tolerably certain, and the custom is still prevalent in some places. Colt's-foot, yarrow, mouse-ear, lettuce, and other plants are occasionally smoked, and no doubt have been so for centuries. A primitive kind of pipe, doubtless such as has been made generation after generation, is still in use in some remote districts. It consists of a stick of elder, from which the pith has been removed, with a bowl formed of common clay, and dried by the kitchen-fire. However much the habit of smoking herbs might obtain in Britain before that time, it is certain that to the introduction of tobacco is to be traced the rise of the trade of the pipe-maker. Pipes have been found in situations near the Roman wall in Northumberland, and other Roman stations in Britain, suggesting the idea that they were used by the Roman soldiers. But this opinion was relinquished by Dr Bruce, the antiquary, who first propounded it; and very few now imagine that any of the pipes to be seen in the antiquarian museums of Europe are many centuries old. The names Danes' Pipes, Celts' Pipes, Elfin Pipes, Fairy Pipes, Old Man Pipes, &c., are popularly given to these old pipes, but afford no evidence as to their real antiquity. Many of them are remarkable for their very small size, whence, perhaps, some of the names; but this is easily accounted for by the consideration of the very high price of tobacco when first introduced into Europe, and the manner in which it was used, the smoke inhaled by the mouth being expelled through the nostrils, so that the narcotic power of the herb was enjoyed to the utmost. Similar very small pipes have also been found in North America, and the same mode of using tobacco has always prevailed amongst the American Indians. See Wilson's *Prehistoric Man*, vol. ii. Stone pipes, or pipe-bowls, have also been found in Britain, cut in rude forms, and which apparently were used by the insertion of a tube, perhaps a straw. Such pipe-bowls, but elaborately carved, are amongst the most remarkable American antiquities. They continue, however, to be made by the American Indians to the present day, often of stones, which are not cut without great difficulty, and are adorned with figures of men and animals. Some of them are adapted for the insertion of two tubes, that two smokers may inhale the fumes of the tobacco at once. Among some of the American tribes, the greatest care is bestowed on the ornamenting of the pipe-stem; by others, on the bowl.

The clay-pipe, much the same as is now used, probably came into use very soon after the introduction of tobacco in Britain. Aubrey, writing in 1680, says that tobacco-smokers at first used silver pipes, 'but the ordinary sort made use of a walnut-shell and a straw.' In the reign of William III., pipes were occasionally made of brass and of iron. Examples of these are preserved in various collections. The pipe was, in the earlier days of smoking, passed round the table—one man taking a whiff or two, and then handing it to his neighbour; thus, one pipe of tobacco would 'suffice three or four men at once.' The annexed cut (fig. 1) represents one of the earliest forms of the clay-pipe, undoubtedly of the

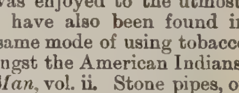


Fig. 1.—Pipe of the time of Queen Elizabeth.

Elizabethan period. It has been supposed by some writers that the smaller the pipe, the more ancient is its date; but this is decidedly an error. The better criterion of age is the *form*, and the following examples will shew the most prevalent shapes at different periods. The barrel-shaped bowl was most usual during the Commonwealth and the reign of Charles II., although it was made in many various shapes, which are well known from representations of them in prints of the time and on traders' tokens. The annexed cut (fig. 2) represents English tobacco-pipes of the 17th century. In the reign of William III., a more elongated form of

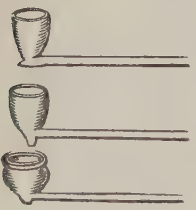

Fig. 2.

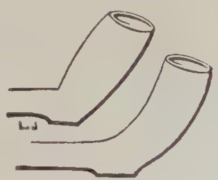

Fig. 3.

bowl (fig. 3) began to be prevalent, probably introduced from Holland, although the barrel-shaped bowl still continued to be used. In the middle of the 18th c., the wide-mouthed bowl, now so universal, became the prevalent form, and the spur, which had hitherto been flat, to rest the pipe upon when in use, was elongated, after a fashion supposed also to have originated in Holland. The Scottish *cutty-pipe* and Irish *dudeen* are short clay-pipes.

The most celebrated seat of the pipe-manufacture in Britain is Broseley, in Shropshire, where it appears to have been established in the middle of the 16th c., and has continued uninterruptedly to the present day. Many hands are employed, and many gross of pipes 'turned out' daily. Pipes are, however, made in many places, the clay being obtained from Purbeck.

The pipe-makers of London, as early as 1601, had privileges which gave them a monopoly. In 1619, the craft of pipe-makers was incorporated in England. Holland has long been famous for pipe-making. The Dutch manufacturers were very jealous of rivalry. In the middle of last century, a pipe-manufactory was established in Flanders, and the Dutch makers determined to ruin it. The duties were too high to admit of a large importation, and they therefore freighted a large ship entirely with tobacco-pipes, set sail to Ostend, and purposely wrecked her there. In accordance with the maritime laws of that city, the pipes were landed from the wreck, and sold at such 'ruinous prices' as defied competition; and the new manufactory at once sunk, and was closed.

TOBA'GO, one of the Windward Islands (see ANTILLES) belonging to Britain, lies 60 miles south-east of Grenada, and 18 miles north-east of Trinidad, is 32 miles long, from 6 to 9 broad, and has an area of 97 sq. miles. The island was discovered by Columbus in 1498, and named by him Assumption; the name of T. is supposed to have arisen from the free use of tobacco by the Caribs when first visited by Europeans. It came into British possession in 1764. From its gloomy-looking mountains, dense forests, and abrupt precipices, descending to the sea, T. has been called the 'Melancholy Isle;' but, on a nearer approach, the aspect becomes more pleasing, though still rough and irregular, being extensively occupied with conical hills and spurs, all connected by a ridge running through the interior, the greatest elevation of which is 1800 feet above the level of the sea. From the high ridge descend deep and narrow ravines, which terminate in small alluvial plains. Scarborough is its chief town, pleasantly situated on the shores of Rochley Bay, and at the base of a conical hill rising 422 feet in altitude, crowned by Fort King George. Plymouth, another town, is situated opposite Scarborough, on the lee ward shore, about six miles distant, and is the landing-place for passengers, &c. from the royal mail steamers. Two-thirds of the island is still covered with primitive forests, comprising many varieties of hard-woods and ornamental trees. The geological formation of the island is, on the whole, similar to that of Trinidad. The climate is considered salubrious; the thermometer ranges from 75° to 90°. The pop. in 1870 was 17,304. The island produces sugar, rum, molasses, cocoa-nuts, cotton, coffee, and indigo; pimento also grows wild. The quantity of sugar exported for the ten years preceding 1862, averaged 58,598 cwts.; shewing an increase of 3092 cwts. over the average of the preceding ten years, although labour had been scarce and difficult to obtain. There had been an increase in the number of public schools; and in 1862, 12⅗ of the population were receiving education; a much higher average than in the other West India Islands. The island is governed by a lieutenant-governor, under the governor of Barbadoes as chief.

TOBERMO'RY. See MULL, ISLAND OF.

TOBIT, BOOK OF, one of the most curious and interesting of the Old Testament apocryphal books. It exists at present in Greek, Latin, Syriac, and Hebrew MSS., the texts of which differ considerably, yet not materially, from each other. The oldest and most valuable is the Greek Septuagint; indeed, where the others depart from it, they possess little claim to our respect, although the *original* text was certainly not Greek. When and where the book was written, are questions to which various answers have been given; but the opinion of Ewald, who selects Persia as the scene, and the middle of the 4th c. B.C. as the date of its composition, agrees best with its internal character. The author he imagines to have been a Palestinian Jew who wrote in Hebrew, and conjectures that a translation of the work was made into Alexandrian Greek in the 1st c. B.C. That the contents of Tobit are not historical, scarcely requires proof in modern times; yet up to the period of the Reformation, no serious difficulty was felt in receiving it as such. Luther was the first to speak of it as a 'poetical,' i. e., an imaginary, didactic production; and since his time, biblical critics have been pretty unanimous on the point; although some contend for what they call a historical basis. The leading incidents of the story do not differ by a hairbreadth in grotesque and puerile *miraculousness* from the fantastic extravaganzas of the Arabian Nights. Tobit, sleeping outside the wall of his courtyard one night, is blinded by sparrows 'muting warm dung into his eyes;' his son Tobias is attacked on the Tigris by a fish, which leaps out of the water to assail him; and marries a Jewish maiden called Sara, seven of whose betrothed lovers had been successively carried off by an evil spirit called Asmodeus. Asmodeus is driven off by an angel—who first appears under the name of Azarias, but subsequently turns out to be Raphael—and then flies to the uppermost parts of Egypt, where he is bound. Old Tobit is cured of blindness by an application to his eyes of the gall of the fish that had tried to devour his son. The sentiments are often very pious and didactic, the descriptions of social life are picturesque, and apparently

true, but no excellence of that kind can reconcile us to the childish absurdities of the story.

TOBO'LSK, a government of West Siberia, occupies the north-west angle of the country, and is bounded on the N. by the Arctic Ocean, on the W. by the Ural Mountains, and on the E. by the governments of Yeniseisk and Tomsk. Area, 564,825 sq. m.; pop. (1867) 1,105,855, mostly Russians, but including also Ostiaks, Tartars, Bokharians, and Samoiedes. Branches of the Ural and Altaï Mountains form a hilly region in the west and south-east; but the government is for the most part an extensive plain, sloping to the banks of the principal rivers and to the shores of the Arctic Ocean. The chief rivers are the Ob (q. v.), and its great navigable affluents, the Irtish, Tobol, Om, and Toura. The soil is fertile in the southern and middle districts; marshes covered with forests occupy the land north of lat. 57°, and frozen marshes border the Arctic Ocean. See TUNDRAS. The climate, mild in the middle districts, is severe in the north, and warm in the south. Dogs, martens, ermines, silver and blue foxes, bears, deer, &c., eider-ducks, geese, ducks, &c., are the principal animals. The chief crops are rye, oats, and barley. Agriculture employs the great mass of the inhabitants, except in the north, where hunting and fishing are the general occupations. The luxuriant meadows of the south are taken advantage of for cattle-breeding. Timber, furs, and fish are the chief articles of commerce.

TOBOLSK, a town of Western Siberia, capital of the government of the same name, stands at the confluence of the Irtish and the Tobol, 1976 miles east of St Petersburg. It is well built, with timber houses and wide and regular streets, and its position on the two great rivers is picturesque; but its lower part is subject almost annually to inundation from the high floods of the Irtish in spring. Its situation, considerably north of the great commercial highway between Russia and Siberia, and at a distance from the more productive regions of the country, is unfavourable for the development of commerce. T. contains a large prison, capable of accommodating 3000 prisoners; and the convicts condemned to exile in Siberia are first assembled at this town, and thence deported to various parts of the country. Several regiments are stationed here. Pop. (1867) 20,330.

TOCANTI'NS, an important river of Brazil, South America, rises in the province of Gojas, flows north through the province of Para, and joins the waters of the Para (q. v.), the southern branch of the estuary of the Amazon, 130 miles from the Atlantic. Its principal affluent is the Araguay, which joins it in lat. 6° S., and has a longer course, and bears along a greater volume of water than the stream to which it is tributary. The T., at its junction with the Araguay, is 5500 feet wide; at its mouth, it is 8 miles wide. Total length, 1100 miles. The navigation, which is carried on by trading-boats resembling floating houses, is dangerous, on account of the numerous falls, sandbanks, and rapids. Boats descend from Porto Imperial (lat. 10° 30′ S.) to the mouth of the T. in from 20 to 30 days; the upward voyage to the same port occupies from four to five months.

TOCHER, in the Law of Scotland, is an ancient name for the marriage-portion given by a father on the marriage of his daughter. It is settled according to the wish of the father, or as may be agreed with the intended husband of the daughter. Where the father by will leaves a legacy to his daughter, and afterwards during his lifetime gives her a like sum as a tocher, this is not presumed to be a satisfaction of the legacy, though it is otherwise in England. See MARRIAGE.

TOCQUEVILLE, ALEXIS CHARLES HENRI CLEREL DE, a French statesman, and the most eminent writer of this century on the science of politics, was born at Verneuil, in the department of Seine-et-Oise, 29th July 1805. His father was the representative of an old family, the Clerels, proprietors of Tocqueville in Normandy. The Clerels, although in the direct line *noblesse d'épée*, had been closely connected with the magistracy, and, indeed, might be considered to belong more properly to that order, which in France has produced so many distinguished men. The mother of De T. was a grand-daughter of Malesherbes, the academician, political writer, and magistrate, who defended Louis XVI. at the bar of the Convention, and whose fearless intrepidity was punished by the execution of himself and all the most distinguished of his relations. Madame de Tocqueville and her husband narrowly escaped the guillotine by the fall of Robespierre; but they did not emigrate, like other royalist families, and they preserved their property. At the Restoration in 1815, the father of De T. reassumed the title of Count, which belonged to the family before the Revolution. Young T. was called to the bar at Paris in 1825; and after a short tour in Italy, entered the magistracy as *juge auditeur* at Versailles. In this situation, he carefully studied the administrative system of France; and struck by the perpetual recurrence of revolution, devoted much thought to political questions. In 1831, he threw up his appointment at Versailles, and with his colleague there, M. Gustave de Beaumont, accepted a government mission to America, to report on the working of the penitentiary system. The commissioners, after remaining a year and a half in the United States, returned to Europe, and published their Report (*Du Système pénitentiaire aux Etats-Unis*, 1832; Eng. transl., Philadelphia, 1833)—an admirable work, which modified all the ideas previously entertained in France regarding prison-discipline. But this was not the most important result of their inquiries. In 1835, De T. published his great work, *De la Démocratie en Amérique*. In his introduction, he sought to shew that a great democratic revolution has for centuries being going on in Europe. There is a general progress towards social equality, which must be looked on as a providential fact. In France, it has always been borne on by chance, the intelligent and moral classes of the nation never having connected themselves with it, in order to guide it. In America, he found that the same revolution has been going on more rapidly than in Europe, and has indeed nearly reached its limit in the absolute equality of conditions. There, accordingly, he thinks we may see what is about to happen in Europe. He points out that the people in America may be strictly said to govern. They make the laws and administer them. He draws from what he has observed the conclusion, that democracy may be reconciled with respect for property, deference for rights, safety to freedom, and reverence for religion. He does not propose the laws and manners of the Americans for the imitation of other democratic peoples. He merely seeks, by a faithful picture of an existing democracy, to allay the dread of democratic progress, and to induce those at the head of affairs to recognise it as irresistible, and to seek to control it by wise concessions. *The Democracy* made at once a great sensation. The accuracy of the statements, the skill with which the matter had been digested, and the beauty of the style, were loudly praised by critics. The author was described as the continuator

of Montesquieu, and the greatest political writer of his time. He became successively a member of the Academy of Moral Sciences, and of the French Academy. In 1835, De T. visited England, where his work had made him known, and where he received an enthusiastic welcome from the leaders of the Whig party. In the same year, he married Miss Mottley, an Englishwoman. He shortly afterwards, by a family arrangement, entered into possession of Tocqueville. He stood, in 1837, as candidate for the representation of Valognes in the Chamber of Deputies. His opponent was a retired mill-spinner, who raised the cry of 'No nobles' against him. Alluding to the great dovecot of Tocqueville, his opponent said: 'Prenez garde! Il va vous remener les pigeons.' De T. was defeated; but two years after, he had become a great favourite with his neighbours, the Norman farmers, and they returned him to the Chambers by an overwhelming majority. As a speaker, De T. did not succeed, but he exercised great influence on the legislature. Immediately after the revolution, he was the most formidable opponent of the Socialists and extreme Republicans. He opposed Louis Napoleon, as a man who believed in his right to the throne as firmly as Charles X. He became, however, in 1849, Vice-president of the Assembly; and from June to October in the same year, Minister of Foreign Affairs. At this time, he vindicated the policy of the expedition to Rome, on the ground, it must not be forgotten, that it would secure liberal institutions to the States of the Church. After the *coup d'état*, he returned to Tocqueville, where he devoted himself to agricultural pursuits. He there wrote *L'ancien Régime et la Révolution* (Par. 1856; Eng. transl., New York, 1856), a work worthy of his fame. In June 1858, he broke a blood-vessel, and was obliged to leave the bleak coast of Normandy for a warmer climate. He took up his abode at Cannes, where Lord Brougham and Chevalier Bunsen spared no effort to soothe his lingering illness. He died there, 16th April 1859. T.'s *Œuvres et Correspondance Inédites* were published in 2 vols. (1860), by his friend M. de Beaumont, who prefixed a biographical notice. The Eng. transl. of this work appeared at London and New York in 1861.

TOD (derivation unknown), a weight for wool, now unused; it was fixed at 28 lbs. avoirdupois in 1671.

TODARS, TODAWARS, or TUDAS,* a remarkable race inhabiting the upper part of the Neilgherry Mountains (q. v.), in Southern Hindustan. They are rapidly diminishing in number, chiefly owing to the practice of Polyandry (q. v.), and their not allowing intermixture with other races; in 1858, it appears that only 337 were left. They are tall, well proportioned, and athletic, with finely moulded limbs, and bold, independent carriage; the nose aquiline, with black, bushy hair and beard. The dress of the men consists of a single toga, worn so as to leave the right arm free, not unlike the plaid of the Scottish Highlander. Both sexes are of a dull copper colour but the women are rather fairer than the men, and are often tall and handsome in feature and person. They have no occupation except tending their herds of buffaloes, and converting the milk into butter. The buffalo, indeed, is so important to them, that they look on the pen where the herd is cooped up at night with superstitious veneration. They never attempt the cultivation of the land around them, as they obtain what grain they require from the Burghers and other agricultural tribes, who pay it in the shape of tribute (*goodoo*) for the lands they cultivate, over which the T. assert an imaginary right. The T. hold that their ancestors were the aboriginal inhabitants of these regions (see INDIA, *Inhabitants*); that the Kothers, and afterwards the Burghers, came among them; and that they allowed these tribes to cultivate land on condition of paying a goodoo of one-sixth of the harvest. The Burghers continue to pay this tribute of grain, but only in such amount as suits their own wants and inclinations, and rather in the shape of charity than otherwise. The only use the T. get of the buffalos, besides their milk, is to furnish sacrifices to the manes of the dead. They are wont to salute the sun at his rising and setting, and believe that the soul after death goes to the 'great country.' They have no distinct places of worship, except the hut in which they keep their milk, where they pour out in libations to their deities what remains after their daily consumption. They have never been known to steal the smallest article. No civil servant, or native of any of the other tribes, has ever been able to acquire their language, which has no written character, and not the slightest affinity with Sanscrit. Their mode of collecting the goodoo is singular enough: 'As soon as harvest is over, and the goodoo collected in Todanaad, the Toda men of that division pay visits to the munds (villages, or groups of huts) in Meyleanaad and Paranganaad, and take up their abode with the women of the community (to the temporary exclusion, as is the custom, of the legitimate husband). They then pay visits to the surrounding Burgher villages, and demand in their right, as temporary husbands of the women of the naad, the goodoo, which, strange to say, is paid; and thus the same man, perhaps, who has laid a whole village in his own naad under contribution, goes the round of the other two naads, appropriating the fruits of the Burghers' labour and industry, and carrying off enough grain to support his whole community in idleness and plenty until the arrival of the next year's harvest-time, and to produce by sale in the nearest bazaar sufficient money to pay the tax which is levied yearly on their tribe. I should have refused credence to such a statement, had I not received it on the best authority, that of the tahsildar of the district.'—See *Statistical Memoir of a Survey of the Neilgherry Mountains*, laid before the Select Committee on Colonisation, &c., in 1858, ordered by the House of Commons to be reprinted, 1861; Captain Harkness's *Description of a Singular Aboriginal Race*, &c., 1832; Captain Burton's *Goa and the Blue Mountains*, 1861.

* 'Written also *Toda, Thoda, Thodawur.* The name of a pastoral people inhabiting the Nilghiri Mountains, and claiming to be the original occupants and proprietors of the whole of the hilly country.'—Dr H. H. Wilson's *Glossary of Indian Words.*

TODDY, the name given in the East Indies to the fermented juice of various palms from which Arrack (q. v.) is distilled. The name has been adopted in Britain for a mixture of whisky, sugar, and hot water, which forms the national drink of Scotland and Ireland. See SPIRIT.

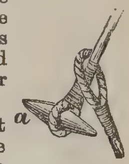
TODLEBEN, FRANZ EDWARD, Russian general of Engineers, was born at Mitau, Russian province of Courland, in 1818. After studying at Riga, he was admitted as a student in the College of Engineers at St Petersburg. He was second-captain in the engineer corps when the Russian army entered the Danubian Principalities in 1853, and served in the campaign of the Danube under General Schilders. His genius as a military engineer was discovered before the Russian army crossed the Pruth, on its retreat from the Principalities; and when the French and English troops undertook the siege of Sebastopol, Colonel T. was sent to assist in

its defence. It was in the middle of April when he arrived, and the fortifications were soon placed under his direction. The principle on which he acted was to watch the works of the allies, and to establish against them on every point a superiority of fire, by multiplying the number and increasing the calibre of his guns. The prodigious activity displayed by the Russians in making good the damage sustained by the heavy fire of the enemy, filled the allied army with astonishment. Everywhere, massive ramparts of earthworks, mounted with formidable batteries, rose up as if by magic at each threatened point within the line of defence. According to T., the defence was rapidly asserting an engineering superiority over the attack. The Malakoff, however, was carried by assault, and the allies entered Sebastopol (see *History of the Russian War* (illustrated), W. & R. Chambers). At the battle of Inkermann, T., who was on the spot by chance, seeing that the Russian artillery was in danger of being taken, promptly halted a regiment, caused four guns to open fire on the allies, and gave time to the artillery to retreat. At the latter part of the siege, he was wounded in the leg, but all his great defences had then been completed. Since the conclusion of peace, he has expanded what was at first a mere engineer's report into a history of the war in the Crimea. It is entitled *Défense de Sebastopol: ouvrage rédigé sous la Direction de Lt.-Gen. E. de Todleben, aide-de-camp général de S.M. l'Empereur.* In this work, he writes a thoroughly Russian account of the Crimean War. In all that relates to the Russian army and its labours, and especially in regard to the work of the siege, the author may be accepted as an unimpeachable authority; but where the British and French armies are concerned, he is too often careless and inexact, and sometimes his statements are absolutely untrue. For his pre-eminent services in the siege, he was rewarded with the rank of General of Engineers, and decorated with the clasps of the order of St George. [Died in 1884.]

TO'FFEE, or TOFFY, a sweetmeat made of sugar, melted with about half its weight of butter. Much care is required in making it, to insure its being crisp when cold. It should be kept over the fire and slightly simmered for a quarter of an hour, when small drops are taken and let fall on a marble slab to cool quickly for trial; if they become brittle, it is complete. Everton, near Liverpool, has a name for its toffee.

Roman Toga.

TO'GA (from Lat. *tego*, to cover) was the principal outer garment of the Romans, and originally, perhaps, the only one. Subsequently, an under-garment, the *tunic*, was added. It was probably of Etruscan origin, and yet it came to be considered the distinctive badge of the Roman citizen, whence the Roman people are called *togati*, or *gens togata;* and consequently, when the Cisalpine Gauls received the rights of citizenship, their country was spoken of as *Gallia togata*, in opposition to Transalpine Gaul, or *Gallia braccata* (breeched). At first, it was apparently semicircular in shape—so, at least, say Dionysius, Quintilian, and others—but afterwards, when it came to be an elaborate and complicated dress, it must have been a smaller segment than a semicircle. The mode of wearing the toga is difficult to describe, and required considerable art to make the folds fall gracefully. The toga was made of woollen cloth, and except in the case of mourners, was of a white colour. Accused persons sought to excite sympathy by going about in a soiled (*sordida*) and unsightly toga; while those who were seeking office were wont to dress themselves out in garments which had been made artificially bright by the help of chalk, hence their name of *Candidati* (lit. shining ones), candidates. The *toga prætexta* had a broad purple border, and was worn by children, and most though not all of the magistrates. The *toga picta*, so called from being ornamented with embroidery, was worn by generals when enjoying their 'triumphs.' Under the emperors, the toga, as an article of common wear, fell into disuse, the Greek *pallium* and other garments being used instead; but it continued to be used by officials on solemn or festive occasions.



Toggel.

TO'GGEL, on Shipboard, a short bar of hard wood, *a*, tapering from the middle towards each end, placed in an eye at the end of a rope, as a convenient obstacle to the rope passing through a loop or knot.

TO'GGENBURG, or TOCKENBURG, a district in Switzerland, within the canton of St Gall, formed by the long and fertile valley of the Thur. It was formerly governed by counts of its own, who ranked as the richest and most powerful land-proprietors in the country. On the extinction of their line in 1436, the possessions passed to the Barons of Rasen, who sold them in 1469 to the Abbot of St Gall. Since 1803, T. has formed part of the canton of that name. The valley is thickly peopled by an industrious race, who carry on the manufacture of muslin and cotton. The most interesting spot in the whole region is Wildhaus, in the Johannisthal, a little mountain village more than 2000 feet above the level of Lake Zürich, where Ulrich Zwingli, the Swiss reformer, was born.

TOISE, in the ancient French system of measures, was the unit of linear dimension, and was divided into 6 feet, each foot (*pied*) into 12 inches, and each inch (*pouce*) into 12 lines (*lignes* or *points*). It is equivalent to 1·94903659 French mètres, or to 6·3946 English feet.

TOKA'T, a town of Turkey in Asia, west from Trebizond, and 60 miles from the south shore of the Black Sea, stands at the mouth of a defile, on the banks of a small stream. It is enclosed by mountains on three sides, so that in summer the heat is intolerable. Gardens and vineyards extend along the slopes of the valley to the distance of three miles above the town. The town consists principally of wooden huts, disposed in narrow and dark streets. It was formerly a place of considerable trade, but its importance as a commercial mart has declined. Extensive copper-furnaces, however, in which copper ore, brought from near Diarbekir, by means of mules and camels, is smelted, still exist, and give employment to many persons. Cotton-printing and dyeing are also carried on. Pop. 35,000.

TOKA'Y, a species of wine obtained from the vines which grow on the Hegyallya Mountains, a group stretching north and north-east of Tokay

The T. wine-district comprises about 15,000 English imperial acres, the produce from the Mezes-mali, a detached rounded eminence near Tokay, being most esteemed. Great care is bestowed on the proper assortment of the grapes (which are never gathered till fully ripe); and also on the preparation of the wine—of which about 34 sorts are reckoned; but all of these may be grouped into the two classes of sweet and dry. The wine is brownish yellow while new, changing to a greenish hue as it grows older. The average annual produce of the T. vineyards is 1,500,000 imperial gallons of the dry, and 50,000 gallons of the sweet, wines. T. wine enjoys an immense reputation on the continent for its great restorative and tonic qualities; and so much is it esteemed in Hungary, that every considerable proprietor for miles round makes it a point to acquire some property in this vine-district, that he may be able to procure his wine from his own vineyards. On this account, genuine T. is obtainable by wine-merchants only in small quantity (and this is especially the case with the more valuable sort, the sweet or imperial T.), and is largely mixed with inferior wines, to increase the amount. The vine-gathering is celebrated at Tokay, Maad, and Tallya, the three chief places of the district, as a national fête, to which the magnates of Hungary with their families flock from all quarters; and during the season of festivity and rejoicing, many times more than the whole value of the vintage is expended. The crowd of visitors is swelled largely by the wine-dealers and medical agents, who eagerly buy up such lots as are for sale, and sometimes give the most extravagant prices for imperial or other good qualities of wine. Large quantities of 'imitation' T. are made by French and German chemists, and sent to all parts of Europe, not excepting Hungary itself, so that purchasers require to guard against imposition by dealing only with the grower or his accredited agent.

TOKEN, the name given to a kind of money which was at certain periods current in Britain by sufferance, and not by royal authority. Tokens first came into use in England in the reign of Henry VIII., in consequence of the want of any authorised coins

Fig. 1.—Token of the Triumph, or Pageant Tavern, Charing Cross, 1661.

to represent the fractions of a penny; and in the reign of Elizabeth, stamped tokens of lead, tin, and even leather, issued by vintners, grocers, and other

Fig. 2.—Token of the Mermaid Tavern, Cheapside, London, about beginning of 17th century.

tradesmen, passed largely from hand to hand, and were payable at the shops where they were issued. The corporations of Bristol, Oxford, and Worcester, had also their tokens. In 1613, a royal proclamation authorised Lord Harrington to issue farthing tokens, and prohibited the use of private tokens under penalties. This prohibition was renewed by Charles I., who granted to the Duchess of Richmond, Sir Francis Crane, and others, the exclusive right of coining authorised farthings for seventeen years; but the farthings made by these patentees were the subject of much discontent, as they were greatly below the intrinsic value of the metal. In the face of these prohibitions, private tokens, principally of brass, continued to circulate, and were especially abundant during the Civil War. Numerous tradesmen's tokens, mostly of copper, were again struck during the scarcity of money at the close of last century. On account of the scarcity of current silver money, previous to the new coinage of 1817, silver pieces known as Bank Tokens, of the respective values of 5*s.*, 3*s.*, and 1*s.* 6*d.*, were issued by the Bank of England: they were called in on the revision of the coinage.—See Chambers's *Book of Days*, vol. i. p. 535.

TOLAND, JOHN, a well-known deistical writer, of the 17th and 18th c., was born near the village of Redcastle, in the county of Londonderry, Ireland, November 30, 1669 (or 1670). His parents were Roman Catholics, and he was brought up in that religion. His baptismal name was James Junius; but the ridicule which it drew upon him at school, led him to change it into John, by which he is now known. He was educated at Redcastle, and entered the university of Glasgow in 1687, but removed to that of Edinburgh, where he took the degree of Master of Arts in 1690. Thence he passed to Leyden, where (having abandoned at Edinburgh the Roman Catholic faith) he entered upon theological studies with a view to orders as a nonconformist minister. One of his masters at Leyden was the celebrated Spanheim. He remained there about two years, during which time he made the acquaintance of Leibnitz and some other distinguished men; and on his return to England, he resided for some time at Oxford, where his extravagant vanity, and the reckless boldness of his opinions on religion, drew on him much notice. In the Bodleian Library, he collected the materials of more than one of his later publications, and prepared in great part the work entitled *Christianity not Mysterious*, which he published in London in 1696, and in which he fully avowed his unbelieving principles. The work created a great sensation in the theological world. It was censured by Convocation, and led to several replies (among which, those of Payne and Stillingfleet may be specially noticed); and in the following year, T. resolved to return to Ireland, sending before him a large number of copies of his work; but he was received no less unfavourably than in England, and his book was burned publicly by the common hangman, in virtue of an express vote of the Irish parliament. Finding it necessary to flee from Ireland, T. returned to London, where he published a defence against this judgment of the Irish parliament; but he soon afterwards turned his pen from theological to political and literary subjects. A pamphlet entitled *Anglia Libera*, on the succession of the House of Brunswick, led to his being received with favour by the Princess Sophia at the court of Hanover; and to his being sent on a kind of political mission to some of the German courts.

During his residence abroad, he published in 1702 a vindication of his book against the judgment of the Convocation, the tone of which was considerably more moderate; but again, in 1705, he outstripped the boldness of his former opinions, and with still less of disguise, openly avowing himself a

pantheist. In this course he was emboldened by the patronage of Harley, in whose service he had engaged as a political pamphleteer, and by whom he was sent abroad to Holland and Germany in 1707, in a capacity which, however he disavowed it, was plainly that of a political spy. He returned to England in 1710; and having forfeited the favour of his patron, or at least having separated from him, he engaged as a partisan pamphleteer on the side of Harley's adversaries.

His after-life was that of a literary adventurer, and was checkered by every variety of literary conflict and pecuniary struggle. It forms one of the most curious and painful chapters in D'Israeli's *Calamities of Authors.* He resided from the year 1718 at Putney, where he died, March 11, 1722, in his 52d or 53d year; and it is observed by Disraeli, that on his table was found an *Essay on Physic without Physicians*, which he was writing, in revenge for the unskilful treatment which he himself had suffered in his malady.

Of his works, which were very numerous, but have never been collected into a uniform edition, the following are the most remarkable: *Christianity not Mysterious: a treatise shewing that there is nothing in the Gospel contrary to Reason, nor above it* (Lond. 1696); *Apology for Mr Toland* (1697); *Life of Milton*, prefixed to Milton's works, 3 vols. folio (1698); *Anglia Libera, or the Limitation and Succession of the Crown explained and asserted* (1701); *Vindicus Liberius, or Mr Toland's Defence of Himself against the Lower House of Convocation* (1702); *Socinianism truly stated* (1705); *Reasons for naturalising the Jews* (1714); *State Anatomy of Great Britain* (1714); *Nazarenus, or Jewish, Gentile, or Mahometan Christianity* (1718). A detailed account of these works would be out of place, but they all exhibit in a general way the characteristics described above. His Posthumous Works were published in 2 vols. 8vo, in 1726, with a life by Des Maizeaux. An *Account of Toland's Life and Writings*, ascribed to Curle, had previously appeared in 1722. It should be added that the above list is far from containing all the writings of this now little known, but once active and notorious polemic.

TOLE'DO, a famous city of Spain, capital of the province of the same name, and long the capital of the whole country, stands on the north bank of the Tagus, by which it is encompassed on three sides, 55 miles south-south-west of Madrid by railway. It is situated on a number of hills at the height of about 2400 feet above sea-level; and the climate, excessively hot in summer, is bitterly cold in winter. The Tagus is the great fortress of the town. Rushing round it, on the east, south, and west, between high and rocky banks, it leaves only one approach on the land-side, which is defended by an inner and an outer wall, the former built by the Gothic king Wamba, in the 7th c.; the latter by Alfonso VI. in 1109, and both remarkable for the number and beauty of their towers and gates. Seen from a distance, the city has a most imposing appearance; within, it is gloomy, silent, inert, and its narrow streets are irregular, ill-paved, and steep. In the middle of the city, rises the lofty, massive cathedral, surrounded by numerous churches and convents, mostly deserted, for here the churches are without congregations, and the streets and walks are almost destitute of people. The cathedral, completed in 1492, and built on the site of a former mosque, is a large edifice, in simple, pointed Gothic. It was ransacked and plundered in 1521 and 1808, but previous to these events, its interior was of the most magnificent description. The stained glass that remains is superb; the choir is a perfect museum of high class sculpture; and there are two pulpits of metal, gilt, the workmanship of which is as fine as that of the richest plate. The cathedral is 404 feet long, and 204 feet wide; and has 5 naves, supported on 84 piers. Connected with the cathedral are an extraordinary number of chapels, of great interest, alike from their architectural beauty, their decorations, and their historical associations. The *Fabrica de Armas*, or manufactory of Toledan swords, a huge building, was erected in 1788, though long before that time the Toledan blades had become famous, having been written about both by Livy and Polybius. The temper of the best Toledan blades is such, 'that they are sometimes packed up in boxes, curled up like the mainspring of a watch.' Pop. (1845) 13,431; (1877) 21,297.

T., the *Toletum* of the Romans, was taken by Marius Fulvius in 193 B. C. It was the capital of the Goths. In 714 it fell into the possession of the Moors, who retained it till 1085, when it was annexed to the crown of Castile. In the days of its highest prosperity, it is said to have contained 200,000 inhabitants.

TOLEDO, a flourishing city of Ohio, at the western extremity of Lake Erie, pleasantly situated on an elevated plain on the banks of the Maumee River, 4 miles from its mouth, 112 miles west of Cleveland, and 65 miles south of Detroit. The river affords a safe and spacious harbour for steamers and vessels of the largest class. T. is the terminus of the Miami and Erie Canal, extending south to Cincinnati, and of the Wabash and Erie, connecting the Wabash at Terre Haute with Lake Erie, together 700 miles in length. T. is connected by railroad with St Louis and Cincinnati, by two roads with Chicago, also with the salt regions of Michigan, the coal of Ohio, and with the East by the leading lines. The commercial facilities of T. are extensive, and are growing with its increasing trade. Her ten grain elevators have a storage capacity of 2,712,000, and can receive and ship daily 460,000 bushels. During the year 1870 T. received 6,581,471 bushels of wheat; 6,294,032 bushels of corn; 4,103,139 bushels of oats; 3,233,971 pounds of wool, and 196,434,693 feet of lumber. In 1870, 245 vessels, of 43,940 tons, entered, and 208 vessels, of 40,306 tons, cleared the port. The declared value of goods imported from foreign countries in 1870 was $283,329, and the exports, $1,836,782. The trade of T. is rapidly increasing. In 1870 there were 91 wholesale houses, doing a business amounting to $16,926,427. The grain commission business reached the sum of $34,506,472. A line of steamers plies to Montreal in connection with a line to Europe direct. The churches, hotels, warehouses, and especially the school-houses of T. are substantial and elegant. There are 34 churches, 1 convent, 3 asylums, 8 school-houses, 4 banks, 4 savings-banks, 3 daily, 7 weekly, and 2 monthly journals, 5 foundries, 16 saw and planing mills, 4 flouring mills, 15 hotels, and 50 manufacturing establishments. It is the third city of Ohio, and increased 130 per cent., according to the census returns, from 1860 to 1870. Pop. in 1870, 31,731; in 1880, 50,137.

TOLERA'TION is the liberty which, in some countries where a particular form of religion is established by law, is allowed to nonconformists to publicly teach and defend their theological and ecclesiastical opinions, and to worship whom and how they please, or not at all. But no permission is thereby given to violate the rights of others, or to infringe laws designed for the protection of decency, morality, and good order, or for the security of the governing power. The enforcement of this class of laws, which have merely civil and political objects in view, is indispensable to the public welfare, and must proceed without regard to the notions of religious duty which their contraveners

may entertain or profess. In Britain, there are still in force certain statutes imposing penalties on opinions and practices generally regarded as impious, and which were thought to be criminal because of their offensiveness to God (see BLASPHEMY); but these laws are seldom executed now, the opinion having become prevalent, that, except when the religious feelings of the public are so wantonly outraged as to make the perpetrator a nuisance, theological error is best opposed by refuting it, and that when those accused of Heresy (q. v.) are men of piety and earnest conviction, any degree of severity short of extirpation tends rather to diffuse than to suppress their tenets. Besides, the right of private judgment in matters of faith and worship is now more generally recognised *in practice* than it used to be, though such is human pride that even yet many resent the exercise, by their neighbours who differ from them, of the freedom which they claim for themselves. They seem to forget the maxim that we should do to others as we would have others to do to us—a principle admirably applied by St Paul to the case of religious differences (Rom. xiv.), and which indeed is the only one that has been found to work well in all circumstances for every sect: it condemns not only political disabilities and restraints unwarranted by the exigences of the state, but still more, that uncharitable treatment through which, almost exclusively, the spirit of intolerance can now find a vent in free Protestant countries. Were it not for the inconsistency thus displayed in our own day by many professing advocates of the right of private judgment, it might seem wonderful that the Reformers, by whom that right was first asserted, and who on no other ground could justify their separation from the church of Rome, became in their turn the persecutors, not only of the Romanists, who had persecuted them, but of such fellow-Protestants as had drawn from Scripture conclusions that differed from their own. Instances of such inconsistency on the part of the Reformers and their successors will be found in the articles CALVIN, SERVETUS, SOCINUS, BIDDLE, and JEWS. In a church claiming Infallibility (q. v.), and believing that salvation is unattainable beyond her pale, it is not only consistent, but to her most earnest members must seem a duty, to prevent by force the spread of what is accounted a fatal heresy; and, in fact, toleration has never been either professed or practised by the church of Rome. See ALBIGENSES, WALDENSES, DOMINICANS, INQUISITION, HUGUENOTS, BARTHOLOMEW'S (ST) DAY, NANTES (EDICT OF), CEVENNES, DRAGONNADES. But even the Puritans (q. v.), though long oppressed themselves, were so blind to the right of others to differ from them, that in their own brief day of power they eagerly repudiated, by word and deed, as a monstrous and impious error, the principle of a universal toleration. In the Assembly of Divines (q. v.) held at Westminster in 1643—1646, the Presbyterian members fought successfully against the proposal of the Independents that all sects should alike be tolerated. 'We hope,' wrote Baillie to his Presbyterian friends in Scotland, 'that God will assist us to remonstrate the wickedness of such a toleration . . . . For this point, both they and we contend *tanquam pro aris et focis*' (Baillie's *Letters*, ii. 328, 350; Bannatyne Club ed.: see also the strong expressions of George Gillespie, another member of the Assembly, in his *Propositions concerning the Ministry and Government of the Church*, prop. 41 and 42). We accordingly find in the 23d chapter of the *Westminster Confession* an assertion of the duty of the magistrate to promote the true religion, and to restrain and punish heterodoxy—a principle which, soon after the Restoration, was found to work very inconveniently for the Presbyterians themselves, the magistrate being then one who differed from them as to what the true religion was. The Independents, on the other hand, had learned the lesson of toleration in Holland—that nursery of liberty in modern Europe—whither they had fled from oppression in the reign of James I.; and it is a mistake to suppose, as some have done, that they were the first to understand and practise the principles of religious freedom. In the 16th c., Zuinglius and the Hungarian reformer Dudith, disclaimed, by word and action alike, the notion that any man is entitled to assume, in his dealings with others, that his own interpretations of Scripture are true, and those of other men, if different, false and culpable. 'You contend,' wrote Dudith to Beza, 'that Scripture is a perfect rule of faith and practice. But you are all divided about the sense of Scripture, and you have not settled who shall be judge. You say one thing; your opponent, Stancarus, says another. You quote Scripture; he quotes Scripture. You reason; he reasons. You require me to believe you: I respect you; but why should I trust you rather than Stancarus? You say he is a heretic; but the papists say you are both heretics. Shall I believe them? . . . . You say that your lay hearers, the magistrates, and not you, are to be blamed, for it is they who banish and burn for heresy. I know you make this excuse; but tell me, have not you instilled such principles into their ears? . . . . Do you not daily teach that they who appeal from your Confessions to Scripture ought to be punished by the secular power? . . . . When you talk of your Augsburg Confession, and your Helvetic Creed, and your unanimity, and your fundamental truths, I keep thinking of the sixth commandment—"Thou shalt not kill."' In the history of England, also, from the Reformation to the Commonwealth, there is, as Bishop Heber has observed, 'abundant proof that (much as every religious party, in its turn, had suffered from persecution, and loudly and bitterly as each had, in its own particular instance, complained of the severities exercised against its members) no party had yet been found to perceive the great wickedness of persecution in the abstract, or the moral unfitness of temporal punishment as an engine of religious controversy. Even the sects who were themselves under oppression exclaimed against their rulers, not as being persecutors at all, but as persecuting those who professed *the truth;* and each sect, as it obtained the power to wield the secular weapon, esteemed it also a duty, as well as a privilege, not to bear the sword in vain.'—*Life of Jeremy Taylor*, p. 27. It is chiefly to the many keen discussions in Holland and England during the century which followed the Restoration (aided, no doubt, by that moderation or indifference which characterised the Protestant churches a hundred years ago—by the ever-increasing number and power of the dissenters—and by that wider mental culture which enables men not only to see that diversity of mental gifts and acquirements naturally leads to diversity of opinion, but, in Cromwell's language to 'think it possible they may be mistaken'), that we must ascribe the tolerant spirit now actuating most of the statesmen of England and the United States, and which has lately made rapid progress among the people at large. Not only is the *right* of free thought and discussion now generally recognised, but its *necessity* to the well-being of mankind is asserted by eminent thinkers. Mr John Stuart Mill, in his able treatise *On Liberty*, thus sums up the grounds on which the necessity of such freedom is affirmed by him: '(1) If any opinion is compelled to silence, that

opinion may, for aught we can certainly know, be true. To deny this, is to assume our own infallibility. (2) Though the silenced opinion be an error, it may, and very commonly does, contain a portion of truth; and since the general or prevailing opinion on any subject is rarely or never the whole truth, it is only by the collision of adverse opinions that the remainder of the truth has any chance of being supplied. (3) Even if the received opinion be not only true, but the whole truth; unless it is suffered to be, and actually is, vigorously and earnestly contested, it will, by most of those who receive it, be held in the manner of a prejudice, with little comprehension or feeling of its rational grounds. And not only this, but (4) the meaning of the doctrine itself will be in danger of being lost, or enfeebled, and deprived of its vital effect on the character and conduct: the dogma becoming a mere formal profession, inefficacious for good, but cumbering the ground, and preventing the growth of any real and heartfelt conviction, from reason or personal experience' (p. 95).

TOLERATION, ACT OF. See ACT OF TOLERATION.

TOLL (Gr. *telos*, a public tax; Gr. *telonion*, Lat. *telonium*, a toll-house; Ang.-Sax. *tol*, Ger. *zoll*, seem related to the root Ger. *zahl-*, Eng. *tell*, to count, to pay), a payment exacted under a royal grant, or some prescriptive usage, or by express statute; such as by the owner of a port for goods landed or shipped, by the owner of a market or fair for articles sold, or by those charged with the maintenance of roads, streets, bridges, &c., for the passage of persons, goods, or cattle. It is essential in a toll that it be for some reasonable consideration; otherwise, it is void. In modern times, the right to take toll is always created by statute, and nothing short of statutory authority will authorise its levy, for it is a species of tax.

Many tolls receive special names, as dues, customs, &c.; and the term toll is now mostly used in connection with turnpike roads (so called from the turnpike or gate turning on an upright axis or pike, at which the tolls are collected) and bridges. See HIGHWAY.

The first express authorisation of a road-toll on record bears date 1346, when a commission was granted by King Edward III. to lay a toll on carriages passing from St Giles to Temple Bar, and also on carriages passing towards Portpool, now Gray's Inn Lane, London, the roads in those places having become impassable from want of other provision for their maintenance. From that small beginning, the turnpike system gradually spread itself over all England, and latterly over Scotland and Ireland. The earliest Scottish Turnpike Act was passed in 1750. Previously, by statutory enactments in 1617, 1661, and 1669, the Scottish highways were made and maintained by what is called the 'statute-labour' system, under which the labouring population could be called on to give six days' work yearly upon the roads in their parishes. This poll-tax, either in the shape of personal labour, or of conversion-money in lieu of it, remained in force, in regard to all but turnpike roads, till 1845, when the General Statute-Labour Amendment Act (8 and 9 Vict. c. 41) abolished it, and substituted assessments on land.

Beginning with 1750, turnpike roads gradually spread over Scotland, under authority of about 400 separate acts of parliament, till there was a very considerable mileage; and in Ireland, the turnpike system extended over all the kingdom. According to a parliamentary Report in 1840, there were in England and Wales 104,772 miles of turnpike roads; and a similar Report for Scotland in 1859 gives 5768 miles of turnpike roads in that kingdom, with 1060 toll-gates thereon. The original erection of toll-gates excited violent opposition in many parts of the country, and their maintenance has frequently led to popular violence and rioting.* Even those who are sensible that good roads are worth paying for at any reasonable cost, have all along felt the toll-system to be an annoyance and obstruction to traffic, from the continual stoppages to pay or exhibit tickets; often unjust in its application; and unnecessarily expensive. The wastefulness of the turnpike system is astonishing to think of. The local acts of parliament, and the constantly recurring litigation, is a serious expense, to begin with; but the chief waste is in the machinery for collecting the revenue. Besides the erection and maintenance of toll-houses and gates (one for every 6 to 8 miles), there were, at the census of 1861, about 6000 persons employed in England and Scotland as toll-collectors; and assuming these to be heads of families with five persons in each, there are (or were) 30,000 individuals to be maintained, which must absorb a high percentage of the revenue levied on the public.

In 1845, Mr William Pagan of Cupar-Fife published a plan of 'Road Reform,' in which he directed public attention to the evils of the toll-bar system, and advised its discontinuance, the substitute proposed by him being a rate on horses, or an assessment on the lands and heritages in each county and burgh, for the support of all roads (statute-labour roads included) and bridges within the respective counties and burghs.

Ireland, which was studded all over with gates on its turnpike roads, took the lead in toll-bar abolition. The roads in the south of Ireland were the first cleared of gates; Dublin and its environs

* Notably in South Wales, in 1843, where a band of conspirators, calling themselves Rebeccaites (in allusion to Gen. xxiv. 60), carried on the systematic demolition of toll gates and houses for nearly a year.

followed; and an act was passed in 1857, abolishing the whole of the remaining toll-bars; and by April 5 following, the toll-bar system, and all its costs and charges and vexations, disappeared from Ireland. There, the supporting of the roads by land-assessment is much preferred to the defunct toll system. The Isle of Man also is overspread with excellent roads, with no tolls upon them. The financial management of roads by turnpike trustees in England and Scotland has proved eminently unsuccessful, there being an accumulation of debt on the turnpike roads in England to the amount of about four millions sterling, and in Scotland, to the amount of two millions and a half.

The question of toll-bar abolition has been much agitated in England—the inconvenience of the system becoming every day more sensibly felt since the introduction of railways. The efforts of the Anti-toll Association of London have succeeded in freeing the suburbs of the metropolis, and a considerable space on both sides of the Thames, from 153 toll-gates. But although there have been repeated inquiries before both Houses of Parliament, shewing clearly the evils of the toll-bar system, no measure has been taken for its entire abolition in any one county of England. In Scotland, several attempts have been made since the Roads Commissioners' Report of 1859, to obtain a general act, compulsory or permissive, for the abolition of all toll-gates within the kingdom—attempts which hitherto have been unsuccessful. Various counties, however, have obtained acts for themselves, for ending their toll-gates, and maintaining all their roads and bridges by assessment on lands and heritages—the rule usually being, that the proprietors should clear off any debt on the roads, and that the maintenance should be divided between proprietors and tenants. The counties which have obtained abolition acts, are: Aberdeen, Banff, Caithness, Cromarty, Elgin, Dumfries, Haddington, Kirkcudbright, Nairn, Peebles, Ross, and Wigton. The following counties never adopted the toll-bar system, but all along maintained their roads by assessment, or by grant from government: Argyle, Bute, Orkney, Sutherland, and Zetland. The other counties still maintain their roads and bridges by the complicated system of turnpike tolls, and statute-labour and bridge-assessments. The toll revenues in these and in most of the English counties have diminished, from the diversion of the through-traffic to railways; while the chief costs, and notably that of collection, remain as great as before. Notwithstanding the prejudices, and narrow mistaken views of personal and local interests, which continue to resist this, as they have resisted most other important reforms, sooner or later, the toll-bar system must apparently give way, and the word 'toll,' as applicable to collection of moneys at gates on public roads, become obsolete.

TOLLENS, Hendrik, the most popular Dutch poet of modern times, was born at Rotterdam, September 24, 1780. At the early age of 14, his father, a merchant in dyestuffs, placed him in his counting-house, and first looked favourably upon, but afterwards discouraged the boy's poetical efforts. The sympathies of young T. were at that time with what was called the patriotic party, who thought that the entrance of the French, in 1795, would be the cure for all political evils, and he made many verses in the spirit of the times. In his 17th year, he began to study English, German, and Latin; but French literature was his favourite study, and translations of French tragedies his chief work. At 19, he published translations from the French poets, under the title of *A Nosegay of Fragrant Flowers culled on French Ground.* Three years later, appeared his *New Songs and Idyls*, in which he first came out as an original poet. Shortly after, followed another collection of miscellaneous poems, which shewed more marked progress; in 1805, his tragedy of *Lucretia*; and in 1806, that of the *Hoekschen and Kabeljaauwschen*, or the Contest between the Nobility and the Towns in Holland, in the olden time—both original pieces of great merit. In 1804, Loots carried off the first prize, and T. the second, for a poem on Hugo de Groot; and in 1806, the order was reversed, when both again sung the death of Counts Egmont and Hoorn. There flowed from his pen an uninterrupted series of songs and poems, in which the warmest feelings were expressed in the most natural and chaste language. Of these may be mentioned, as a few gems, 'William I.,' the 'Victory at Nieuwpoort,' the 'Four Days' Naval Fight,' the 'Cry to Arms in 1815,' the 'Wintering of the Dutch in Nova Zembla,' and the 'National Song of the Netherlands,' which is an echo of the calm but patriotic spirit of the people. His deep fellow-feeling with his countrymen is seen in the poems which he wrote during the Belgian revolution in 1830—1831, as in the heart-stirring poems, 'The Evening Prayer,' and 'The General Prayer-day.' The popularity which T. attained, his poems reaching the fifth edition in 1831, arose chiefly from his singing of subjects always dear to the heart of the nation—of family-life, country, religion, and love—and that in simple, unartistic language, and pure Dutch style. The people loved the poet because they understood him, and his words touched their hearts. T. published *Romances, Ballads, and Legends* (1818); *New Poems* (1821—1829); *Songs of Claudius* (1832); *Poetical Flowers gathered from Neighbouring Nations* (1839); *Scattered Poems* (1840); two volumes (1850), in which, though advanced in life, the tone of his lyre was more beautiful, powerful, and rich than ever. T. died at Rijswijk, October 21, 1856.

Of modern Dutch poets, T. stands in the first rank. The Wintering in Nova Zembla is the most wonderful piece of descriptive poetry in the Dutch language. T. was an excellent man, distinguished for his sincere piety and benevolence. His compassion for the poor comes out in his *Bedelbrief*, or Begging-letter, which he published for the benefit of the distressed in the severe winter of 1844—1845. While the people's poet, he was also God's priest for spreading Christian love among men. In early life, T. belonged to the Roman Catholic Church, and in 1827 joined the Protestant Remonstrants; but both before and after the change, he was essentially a religious man.

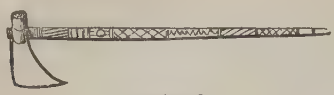
TOLO'SA, a town in the north of Spain, capital of the province of Guipuscoa, 15 miles south of the seaport of San Sebastian. It stands in a deep valley watered by two streams, and abounds in old family mansions. There is a royal factory for arms, and in the vicinity are zinc and lead mines. Pop. about 5000.

TOLU. See Balsam.

TOLU'CA, a town of Mexico, capital of the department of the same name, 20 miles south-west of the city of Mexico. It is handsomely built; beautiful arcades line the streets; and the plain on which it stands is fruitful in maize and other products. Pop. 12,000.

TO'MAHAWK, a light war-hatchet of the North American Indians. The early ones were rudely made of stone, ingeniously fastened to their handles by animal sinews, or cords of skin. European traders supplied hatchets of steel, the heads of which were made hollow, for a tobacco-pipe; the handle of ash, with the pith removed, being the stem. These hatchets are used in the

chase and in battle, not only in close combat, but by being thrown with a wonderful skill, so as always to strike the object aimed at with the edge



Tomahawk.

of the instrument. The handles are curiously ornamented. In the figurative language of the Indians, to make peace, is to bury the tomahawk; to make war, is to dig it up. The engraved figure of a tomahawk is from George Catlin.

TOMA'TO, or LOVE-APPLE (*Lycopersicum esculentum*), a plant of the natural order *Solanaceæ*, formerly ranked in the genus *Solanum*, and known as *S. Lycopersicum*. The genus *Lycopersicum* is distinguished by a 5—6-parted calyx, a wheel-shaped 5—6-cleft corolla, five stamens, and a 2—3-celled berry, with hairy seeds. The T. is an annual, from two to six feet in height, requiring support when tall. The leaves are unequally pinnate, the leaflets cut; the flowers numerous, followed by berries, which are very various in shape and colour—generally red and yellow—in different varieties. The plant is a native of the tropical parts of America, but is now much cultivated in all parts of the world suitable for it, as the south of Europe and the United States. In Britain, it requires a hot-bed in spring. The fruit is much used for sauces, ketchup, preserves, confectionary, and pickles. The unripe fruit makes one of the best of pickles. Tomatoes appear with almost every dish in Italy. The use of them is rapidly increasing in Britain and other countries.

TOMB (Gr. *tymbos*), a monument erected over a grave, in order to mark the resting-place, and preserve the memory of the deceased. In early ages, and among eastern nations, it sometimes became the practice to place the remains of the dead in excavated sepulchres, whose interior was often decorated with painting or otherwise. Where the usage was to burn the dead, their bones and ashes were placed in urns in these receptacles. Some of the most remarkable rock-tombs were those of Egypt, belonging to the 18th and following dynasty of the Theban kings. The monarch's burial-place began to be excavated as soon as he ascended the throne, and the excavation went on year by year, the painting and decoration progressing till the king's death, when it was suddenly broken off, the tomb thus becoming an index both of the king's magnificence and of the length of his reign. The most costly articles are often found in these sepulchres. The decoration was almost entirely reserved for their interiors, the façades being comparatively unobtrusive. On the other hand, the rock-tombs of Persia and Lycia, less rich and elaborate internally, have imposing architectural façades, those of the Persian kings being copied from their palaces; and during the Roman period, this species of magnificence prevailed at Petra (q. v.) to an extent that gives that now deserted valley the aspect of a city of the dead. See also ETRURIA.

Tombs, in more modern times, have generally been mounds or masses of building raised over the remains of the dead. In the Homeric poems, heaps or cairns of stones are placed as honorary memorials above the graves of departed heroes. The Sepulchral Mound (q. v.) or tumulus of rude ages is found over the greater part of Northern Europe, and is probably older than the subterranean tomb. The Pyramids (q. v.) were the sepulchres of the Egyptian monarchs from the 4th to the 12th dynasty. The tombs of Greece, and still more those of the Greek colonies in Asia Minor, were sometimes pillars, or upright stone tablets, sometimes small buildings in the form of temples. The most celebrated was the *Mausoleum* (q. v.). The Roman tombs were not unfrequently important architectural structures, varying in form, but oftenest consisting of a circular tower resting on a square basement; familiar examples being the tomb of Cæcilia Metella, and the yet larger and more solid tomb of Hadrian, on the banks of the Tiber, best known as the Castel St Angelo, which is about 220 feet in height, and of immense solidity. In Rome, Latium, and Magna Græcia, tombs were generally erected outside the towns, and along the principal roads leading into the country, as in the Via Appia at Rome, and the Street of Tombs at Pompeii. A form of excavated tomb, without external architecture, called *Columbarium* (q. v.), was also in use in Rome, whose walls were pierced with cells to receive cinerary urns. The prevalent circular tomb became in the later period of the Roman Empire polygonal; and the central chamber, at first small, was gradually increased, till, in the age of Constantine, it became something like a miniature representation of the Pantheon, generally with a crypt below the principal apartment.

In the earlier centuries of Christianity, the burial of the dead in churches was prohibited. The first step which led to its adoption was the custom of erecting churches over the graves of martyrs; then followed the permission to kings and emperors to be buried in the church porch. The most important tombs of the middle ages are generally within churches or cloisters. There is much variety in the form and enrichment of medieval tombs. The earlier examples consist of a simple stone coffin, or sarcophagus, often with a low gabled lid and a sculptured cross. An altar-tomb, or tomb in the form of a table, followed; and in the 13th c., a species of tomb was introduced, consisting of a sarcophagus, on which rests a recumbent figure of the deceased, the whole being surmounted by a canopy, often of exquisite symmetry and richness. In the renaissance period of art, the tombs became more and more complex. The sarcophagus was disguised, or made the least important part of the monument; the representation of the deceased was confined to a medallion likeness, and the most prominent part of the tomb was composed of sculptured upholstery, and groups of symbolical and eventually mythological figures. In some of the 16th c. examples, as Michael Angelo's tombs of Giuliano and Lorenzo di Medici, at Florence, the inappropriateness of the design is partly redeemed by the beauty of the figures; but in the succeeding centuries, the vicious taste of these monuments rapidly increased, till it culminated in some of the hideous tombs that disfigure Westminster Abbey and St Paul's.

TO'MBAC, or WHITE-COPPER, is an alloy formed of about 75 parts of copper and 25 parts of arsenic; it is used in the manufacture of buttons, and is a very beautiful metal.

TOMSK, a government of Western Siberia, bounded on the E. and N.-E. by the government of Enisei or Yeneseisk, and on the N.-W. and W. by that of Tobolsk. Area, 324,275 sq. m.; pop. 714,746. T., more than any other government of Siberia, abounds in lakes and rivers. Of the latter, most of which flow northward from the foot of the Altaï Mountains, the principal are the Ob, Tom, Chulim, and Irtish. The largest lakes, which are both sweet and brackish, occur in the Barabinsky

Steppes. The climate is mild in the middle and southern districts, but severe in the north. Sandy and clayey soils prevail; but there are patches of good mould on which abundant crops of grain of various kinds, as well as hemp, flax, and tobacco, are raised. The extensive mountain-slopes and plains are covered with luxuriant forests, in which the most common trees are the broad-leafed oak, the cedar, and the pitch-tree. The natural products of the country are numerous. In the south and east parts, droves of wild horses and herds of horned cattle are a source of considerable wealth. But the mineral products of the country are its chief source of riches. Manufactures are not extensively carried on; there is a large barter-trade with China, and the commerce of the country is maintained for the most part by means of fairs.

TOMSK, a trading-town of Siberia, capital of the government of the same name, on the Tom, a tributary of the Ob, 2809 miles east of St Petersburg, in lat. 56° 30′ N., and long. 84° 58′ E. Situated on the great trading highway of Siberia, it is the seat of an important transit-trade, chiefly with the Kalmucks and Mongols; but the goods that pass to and from Irkutsk also go by way of this town. There are upwards of 50 manufactories, chiefly for soap, leather, and distilled liquors, and the most important commercial article is furs. It is said to be the richest town in Siberia; and its commercial importance, its extent, and the number of its handsome buildings, are increasing annually. Pop. about 25,000.

TON, a suffix of frequent occurrence in the names of Anglo-Saxon settlements. It seems to be from the same root as the Gothic *tains*, meaning a twig (allied to which are the *tine* of a fork, the *tines* of a stag's horns, the *tines* of a harrow), the Ang-Sax. *tynan*, to hedge, and the Ger. *zaun*, a hedge. 'Hence, a *tun* or *ton* was a place surrounded by a hedge, or rudely fortified by a palisade. Originally, it meant only a single homestead or farm, and this use of it is still common in Scotland. In modern English, in the form of *town*, it is applied to a collection of houses. Similarly with *ton*, the terminations *worth*, *fold*, *garth*, *burgh*, and others also convey the notion of enclosure, protection.'—See I. Taylor's *Words and Places.*

TON, the same word as TUN (q. v.), denotes a weight of 20 hundred-weight (*cwt.*). In Britain, the hundred-weight contains 112 lbs., so that the ton contains 2240 lbs. In the United States the hundred-weight is usually reckoned at 100 lbs., and the ton at 2000 lbs. In both countries, 40 cubic feet of rough or 50 of hewn timber constitute a ton or load of the same. The hundred-weight (*centner*) in Austria, Prussia, Denmark, Germany, and Switzerland, contains 100 lbs.; in Hamburg, 112; in Bremen, 116; its representative in France, Spain, and Portugal, is the Quintal (q. v.); in Italy, the Centinajo; in Turkey, Egypt, Northern Africa, and the Balearic Isles, the Kantar (124 lbs.).

TONE, in Music, the name given to the larger intervals in the diatonic scale, so called in contradistinction to the *Semitones* (q. v.), or smaller intervals. Theoretically, some of the intervals called tones are larger than others, and none of them are equal to two semitones; thus, in the scale of C, the intervals CD, FG, and AB, are all equal; but DE and GA, which are also called tones, are smaller; and the semitones, EF and BC, are larger than half even of the larger tones. In instruments, however, which are tuned according to the equal temperament (see TEMPERAMENT), all the tones are made equal, and each equivalent to two semitones.

TO'NGA BAY, a small inlet on the east coast of Africa, bounded on the N. by Cape Delgado, and extending inland in a north direction. Cocoa-nut trees and jungle line the shores of the bay, and at its head is the village of Tonga, small and insignificant, but important from its frontier position. Cape Delgado is the northern limit of the Portuguese colonial possession of Mozambique; and the village of Tonga, which is situated north of the parallel of latitude of the Cape, is in the possession of the Imaum of Muscat, and is the most southern possession of that sovereign.—*Despatches from Her Britannic Majesty's Consul and Political Agent, Zanzibar*, 1863.

TONGA ISLANDS AND TONGATABU. See FRIENDLY ISLANDS.

TONGRES, a very ancient city of Belgium, in the province of Limbourg, 13 miles south-south-east of Hasselt. Its church of Notre Dame, the first dedicated to the Virgin north of the Alps, dates from 1240; and the cloister attached, the oldest in the country, was built in the 10th century. The mineral spring in the vicinity, of which Pliny wrote: '*Purgat* hic corpora, tertianas febres discutit, calculorumque vitia,' still retains its ancient virtues. Various manufactures are carried on. Pop. 6800.

TONGUE, THE, is a symmetrical muscular organ, extending from the hyoid bone backwards and downwards, to the lips in front, and occupying the buccal cavity. The superior surface, borders, and anterior third of the inferior surface, are free; while the remaining parts are attached to adjacent

The upper surface of the Tongue, shewing the Papillæ:

1, the raphé or mesial line; 2, 2, the lateral parts; 3, the tip; 4, 4, the sides or edges; 5, 5, the V-shaped mass of circumvallate papillæ; 6, the foramen cœcum; 7, the mucous glands at the root of the tongue; 8, the epiglottis; 9, 9, 9, the fræna epiglottides; 10, 10, the greater horns of the hyoid bone.—From Sœmmering.

parts by the investing mucous membrane and subjacent structures. At certain points, this membrane, on leaving the tongue, forms distinct folds, containing fibrous or muscular tissue, which act to a certain extent as ligaments to the tongue. The most considerable of these folds is termed the *frænum* (or bridle) of the tongue, and connects its anterior free extremity with the lower jaw. It acts as a strong ligament, and limits the backward movement of the tip of the tongue. In rare cases, this ligament extends abnormally to the tip, so as to interfere with speech

and mastication, and the child is said to be *tongue-tied;* recourse must be then had to division of the frænum, popularly known as *cutting the tongue.* Other folds of mucous membrane (the *glosso-epiglottid* folds) pass from the base of the tongue to the epiglottis; while from the sides of the base, passing to the soft palate, are seen two folds on either side, known as the *pillars of the fauces.* See PALATE. The *superior surface* of the tongue is divided into two symmetrical lateral parts by a median longitudinal furrow, commencing at the tip, and extending back about two-thirds of the tongue's length. The various kinds of papillæ which are seen on their surface are described in the article TASTE, ORGAN AND SENSE OF. At the back of the surface, just behind the circumvallate papillæ, are large mucous glands, extending into long and capacious canals, and helping to secrete the fluid that moistens the tongue. On the *inferior surface,* the longitudinal furrow, which extends from the tip to the frænum, is deeper than on the upper surface; on each side of it, veins are seen running forwards; and immediately beneath the tip is a cluster of mucous glands, known as the glands of Nuck (their discoverer in 1690). The *posterior extremity,* or *base,* is flattened and extended laterally before it is inserted into the *hyoid bone* (known also as the *lingual* or *tongue bone*), which, with certain ligaments, must be regarded as the basis or framework of the tongue. The muscles of the tongue are usually divided into two groups—viz., the *extrinsic* muscles, which attach the tongue to certain fixed points external to it, and move it on them; and the *intrinsic* muscles, which pass from one part of the tongue to another, constitute its chief bulk, and move it on itself. These intrinsic muscular fibres run vertically, transversely, and longitudinally, and are so interlaced as mutually to support one another, and to act with the greatest advantage. By the action of the various muscles, the upper surface of the tongue may be made concave or convex, or may be pressed against the roof of the mouth; the tip may be protruded straight out or laterally, upwards and downwards, and to any recess (as, for instance, a hollow tooth) within the mouth where food might lodge; and the whole organ may be drawn back. The organ is freely supplied with blood, mainly by the lingual artery, which is given off by the external carotid. With regard to the nerves, the glosso-pharyngeal and certain branches of the third division of the fifth nerve are concerned in the special sense of Taste (q. v.); other branches of the fifth nerve are concerned in ordinary sensation, while the hypoglossal nerve on each side is the motor nerve of the tongue.

The various uses or functions of the tongue cannot be thoroughly understood without a brief reference to its comparative anatomy. The tongue in mammals does not differ very materially from that of man; but in general there is a close coincidence both in size and form between this organ and the lower jaw. In the rodents, the tongue has a wedge-like shape. In the giraffe and the ant-eater, the tongue is much prolonged, being an important prehensile organ in the former; while in the latter, it is driven into ant-hills, and the victims are secured by its viscid secretion. In the feline races, the conical papillæ are converted into recurved spines of great size and strength, which the animal uses in scraping bones and in combing its fur. Except in mammals, the tongue is probably not an organ of taste. For a good description of the tongue in birds, reptiles, and fishes, the reader is referred to Professor Owen's *Anatomy of the Vertebrates,* vols. i. and ii. Amongst the Mollusca, the Gasteropoda are provided with a very singular apparatus known as the tongue, and consisting generally of a thin membrane, long and narrow, and rolled, except at its anterior extremity, into a tube. This membrane is covered on its upper surface with transverse rows of minute teeth, or more commonly with plates having tooth-like siliceous projections. These teeth present a great variety of patterns, which are constant in the different genera, and even characterise the species. Two eminent naturalists, Messrs Loven, a Swede, and Troschel, a German, have independently made the teeth of the Mollusca a basis of classification. The Articulata do not present anything like a true tongue, although in insects a certain oval appendage is described as a *lingua.*

The functions of the tongue are gustation, prehension (in man and monkeys this function is supplied by the hand), mastication, insalivation, deglutition, and speech; to which may be added, spitting and whistling, and in the case of the Gasteropoda, the trituration of the food.

Amongst the diseases of the tongue may be mentioned INFLAMMATION or GLOSSITIS. The most marked characteristics of this affection are great swelling, tenderness, and difficulty in speaking and swallowing. It rarely occurs as an idiopathic or spontaneous affection, but often accompanies severe salivation. It must be treated by purgatives and low diet, and by gargling, as in ordinary Salivation (q. v.). Incisions are sometimes useful, both to relieve tension, and by the depletion that ensues. Cases occasionally occur in which the tongue suddenly enlarges to an immense size, so as almost to cause suffocation, without any true sign of inflammation.—See Druitt's Surgeon's *Vade-mecum,* 8th ed., p. 454, foot-note.

Hypertrophy, or *persistent enlargement* of the tongue, sometimes results from an imperfectly cured case of inflammation; but is probably in most cases congenital, although perhaps not noticed for a year or two. Bertholin (*Hist. Centur.* iii. p. 85) mentions the case of a male child born with the tongue protruding out of the mouth as large as a filbert; and as the child grew, the tongue increased to the size of a calf's heart. For a reference to various cases, and for the mode of treatment, we may refer to a Memoir by Dr Humphry in vol. 36 of the *Medico-Chir. Transactions.* One of the most common forms of disease of the tongue is *ulceration,* which may arise (1) from the irritation of a decayed tooth with a sharp jagged edge; or (2) from constitutional syphilis; or (3) from a disordered condition of the digestive organs. In the first case, the tooth must be removed; in the second, iodide of potassium with sarsaparilla should be tried; and in the third the complaint generally yields to regulation of the diet and of the digestive organs, and sedatives at bedtime. M. Lawrance recommends a mixture of compound decoction of sarsaparilla with compound decoction of aloes, three times a day, and four grains of extract of hyoscyamus at bedtime, with advantage. *Cancer* of the tongue occurs either in the hard or in the epithelial variety. There is a popular belief that this terrible disease may be excited by the irritation caused by a broken tooth, or by smoking a clay-pipe; but on comparing the prodigious numbers of jagged teeth and of clay-pipes with the rare cases of cancer of the tongue, we must at once reject this hypothesis. All that such sources of irritation can effect is to determine the exact seat of development of cancer in persons predisposed to it. A typical case of epithelial cancer of the tongue occurred in the person of Professor Reid of St Andrews, the eminent physiologist. In December 1847, his age being then 39, and his health good, he noticed a small ulcer on the right side of the tongue; it slowly extended, and acquired

hard everted edges, but caused little inconvenience. In July 1848, it had attained the size of a five-shilling piece; its surface and edges were ragged, and it caused considerable pain, especially at night. A hard ridge could be felt all round the ulcer, and the glands beneath the jaw became enlarged. The health by the end of August had completely given way from the pain, when the diseased part of the tongue was removed by Mr (now Sir William) Fergusson. In less than a month, the wound had healed, and the health was re-established. In November, the enlarged glands were removed; but the disease returned in their scars, and spread till it caused death in July 1849. The only treatment which can be adopted with any chance of success is full and early extirpation. Mr Syme succeeded in removing the whole organ, without even—strange to say—much affecting the patient's speech or power of deglutition. *Tongue-tie* is an affection for which infants are often brought to the surgeon, and which is often performed when it might be dispensed with. The division of the *frænum* with a blunt-pointed pair of scissors, with their point directed downwards, is very easily performed, and fortunately does no harm to the child. Children who do not speak so soon or so clearly as is expected by their mothers, are always supposed to have tongue-tie.

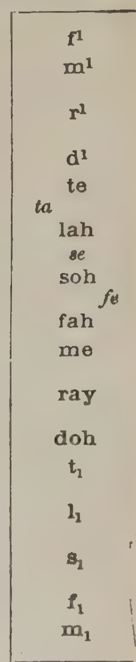
TONGUES, Gift of, a gift of the apostles and other Christians in the first ages of the church. The main passages in the New Testament relating to it are Acts ii. 3—21; 1 Corinthians xii. 10, 28; xiii. 1, and particularly xiv. Allusions to it will also be found in Mark xvi. 17; Acts x. 46, and xix. 6. The only allusion to the possession of the gift in later times is in Irenæus, *Adv. Hær.* vi. 6: 'We have many brethren in the church having prophetical gifts, and by the Spirit speaking in all kinds of languages.' From these data, the following conclusions have been drawn by one of the most recent and intelligent expositors of the Epistles to the Corinthians. The gift in question is represented as something entirely new in the apostolical age: 'They shall speak with new tongues,' Mark xvi. 17. The effect on the spectators at the day of Pentecost is of universal astonishment. It is represented as a special mark of conversion, immediately preceding or following baptism. It is a gift 'of the Spirit:' 'They began to speak with other tongues, as the Spirit gave them utterance'—Acts ii. 4. It was, moreover, closely connected with the gift of 'prophesying'—1 Corinthians xii. 10, 28; xiv. 1—6. It appears to be distinguished from prophesying by consisting not of direct warning, exhortation, or prediction, but of thanksgiving, praise, prayer, singing, and other expressions of devotion. It was an utterance of the heart and feelings, rather than of the understanding, so that the actual words and meaning were generally unintelligible to the bystanders, and sometimes to the speakers themselves: 'He that speaketh with a tongue speaketh *not to men, but to God;* for no one heareth; and in the Spirit he speaketh mysteries'—1 Corinthians xiv. 2, 4, &c. So far, the account of the gift seems intelligible. It was, as Dean Stanley says, 'a trance or ecstasy, which in moments of great religious fervour, especially at the moment of conversion, seized the early believers; and this fervour vented itself in expressions of thanksgiving, in fragments of psalmody or hymnody, and prayer, which to the speaker himself conveyed an irresistible sense of communion with God; and to the bystanders, an impression of some extraordinary manifestation of power, but not necessarily any instruction or teaching, and sometimes even having the appearance of wild excitement, like that of madness or intoxication.' The special difficulty, however, remains, viz., as to the character of intelligibility which, on one prominent occasion, seems to have belonged to the gift. *Glōssa*, or the word translated 'tongue,' does not necessarily imply a distinct language of a people; this is usually expressed in the New Testament by *dialektos*. But in the description in the Acts ii. 6, 8, it is expressly said: 'Every man heard them in his *own language*' (*tē idia dialektō*). 'How hear we every man in *his own language*' (the same phrase in the original) 'wherein we were born.' The plain meaning of this account seems to be, that the gift of tongues, on this occasion, at anyrate, assumed the form of intelligible communications in foreign languages. But there is no evidence that the apostles then, or at any subsequent time, enjoyed the ability, supernaturally imparted, of speaking a variety of languages, with a view to the more adequate discharge of their apostolic functions, as has sometimes been inferred from the passage in the Acts. 'Probably,' it has been said, 'in no age of the world has such a gift been less needed. The chief sphere of the apostles must have been within the Roman Empire, and within that sphere, Greek or Latin, but especially Greek, must have been everywhere understood. Even on the day of Pentecost, the speech of Peter, by which the first great conversion was effected, seems to have been in Greek, which probably all the nations assembled would sufficiently understand; and the speaking of foreign dialects is nowhere alluded to by him as any part of the event which he is vindicating and describing.'—Dean Stanley (*Corinth.* p. 250).

TONIC, or KEYNOTE, in Music, the note which forms the basis of any scale or key, and on which a piece of music written in that key naturally closes. See Key.

TONI'CITY, Muscular. The contractility of muscles shews itself under two distinct forms—*Irritability* and *Tonicity*, which are alike distinct in the mode of their action and in the conditions requisite for their exhibition. Irritability is most manifest in the voluntary muscles and in the heart, which, when in activity, exhibit powerful contractions alternating with relaxation; while Tonicity is shewn in a moderate and permanent contraction, which, instead of being consequent upon stimulation through the nerves, as in irritability, is especially excited by change of temperature in the tissue itself, and is mainly shewn in the involuntary or non-striated muscles. Like irritability, it is an inherent property of muscular tissue during life. 'It manifests itself,' says Dr Carpenter, 'in the retraction which takes place in the ends of a living muscle when it is divided (as is seen in amputation); this retraction being permanent, and greater than that of a dead muscle. But its effects are much more remarkable in the non-striated form of muscular fibre; and are particularly evident in the contractile coat of the arteries, causing the almost entire obliteration of their tubes, when they are no longer distended with blood.' It is to the moderate action of the tonicity of arteries that their contraction upon the current of blood passing through them is due. If the tonicity be excessive, the pulse is hard and wiry; but if it be deficient, the pulse is very compressible, though bounding, and the flow of blood is retarded. From the experiments of John Hunter and many subsequent physiologists, it is established that *cold* is the most efficient agent in inducing tonic contraction; while the application of moderate warmth causes a relaxation of this contraction. Thus, cold and heat are of extreme value as remedial agents, when the tonicity of the blood-vessels is deficient or excessive.

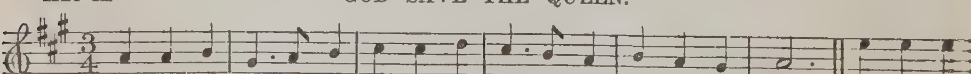
TONICS are medicines which, in cases of want of *tone* or *tonicity* in the muscular fibres, are employed to restore strength and vigour to the system. Tonics, to a certain degree, are stimulants; but while the latter produce a rapid but transitory excitement, the former slowly induce a certain degree of excitement, and the effect is permanent. Most tonics, in which category we must place the shower-bath, cold sea-bathing, open-air exercise, friction, &c., as well as actual medicines of this class, act primarily through the nervous system (iron being, perhaps, the only exception); and secondarily produce their effects upon the muscular system at large. It is not only in general muscular debility that tonics are to be employed, but in all the numerous complaints which follow in its train, as palpitation, convulsions, epilepsy, chorea, neuralgia, and all forms of periodic disease. Amongst the chief medicines of this class are the dilute hydrochloric, nitric, nitro-hydrochloric, and phosphoric acids, various salts of bismuth, copper, iron, silver, and zinc, the various kinds of cinchona bark, with their alkaloids and their salts, cusparia, calumba, cascarilla, chiretta, gentian, quassia, salix, simaruba, and taraxacum. Although nux vomica and its alkaloid strychnine are placed by writers on Materia Medica amongst the 'special stimulants,' when given in very small doses they have a well-marked tonic action; and there is probably no tonic medicine of more general utility than the *Syrup of Iron, Quinine, and Strychnine*, a non-officinal but widely-used preparation, of which every drachm (the ordinary dose) contains $\frac{1}{32}$th of a grain of strychnine.

TONIC SOLFA. Various attempts have been made at different times to introduce a musical notation in which the staff with its lines and spaces is dispensed with. Jean Jacques Rousseau suggested, but afterwards discarded, a notation where the notes of the scale were indicated by the Arabic numerals. A system similar to Rousseau's in its leading features, called the Tonic Solfa, has, through the influence of its principal promoter, the Rev. John Curwen (who obtained his main principles from the writings and practice of Miss Glover of Norwich), been brought into use to a considerable extent in singing-schools in Great Britain. It proceeds on the principle of giving the chief prominence to the fact, that there is in reality but one scale in music, which is raised or lowered according to the pitch of the key. The seven notes of the diatonic scale are represented by the Solfeggio (q. v.) syllables, or rather Miss Glover's modification of them—*Doh, Ray, Me, Fah, Soh, Lah, Te; Doh* standing for the keynote in whatever key the music is written. In the early exercises, the pupils are accustomed to a scale or diagram, called the Modulator, representing pictorially the exact intervals of a key, with the semitones in their proper places. In written music, only the initial letters of the solfeggio syllables are used—d, r, m, f, s, l, t; the higher octaves of a given note being distinguished by a ^{1} above, as d^1, r^1; and the lower by a $_1$ or $_2$ below, m_1, m_2. The name of the key is prefixed to a tune as its signature, as 'Key A,' 'Key B flat'—the keynote being, in all the major keys, *doh*. To indicate rhythm, a perpendicular line | precedes the stronger or louder accent, a colon : the softer accent, and where necessary, a shorter perpendicular line | the accent of medium force. Preparatory to writing the notes, the accent-marks are placed at equal distances along the page—thus, | : | : or : | : : | : : | : or | : | : | : | : A note immediately following an accent-mark, is supposed to occupy the time from that accent to the next—thus, | d : d : d | d : d : d | d, or | d : r | m : d. A horizontal line indicates the continuance of the previous note through another *aliquot* (the term used by Mr Curwen for the distance of time between any accent and the next)—thus, d : — | d : d. A dot divides an aliquot into equal subdivisions, d : m.r | d. A dot after a mark of continuance indicates that the previous note is to be continued through half that aliquot—thus, | d : –. f | m : d. A comma indicates that the note preceding it fills a quarter of the time from one accent to the next—thus, | d : r.m,f | ; a dot and comma together, three-quarters—thus, | f.,m : r.,d. An inverted comma ‘ is used to denote that the note preceding it fills one-third of the time from one accent to the next—thus, : d | s : l‘s‘f | m : r | d. An aliquot or part of it unfilled, indicates a rest or pause of the voice. A line below two or more notes signifies that they are to be sung to the same syllable. We subjoin an example of the tonic solfa shewn alongside of the ordinary notation:



Modulator.

KEY A. GOD SAVE THE QUEEN.



| d :d :r | t_1 :–.d :r | m :m :f | m :–.r :d | r :d :t_1 | d :— :— ‖ s :s :s

| s :–.f :m | f :f :f | f :–.m :r | m :f.m :r.d | m :–.f :s | l‘s‘f :m :r | d :— :— ‖

In modulating into a new key, the note from which the transition is taken is indicated by a combination of the syllabic name which it has in the old key with that which it has in the new—*me lah*, for example, being conjoined into *m'lah;* and in writing this note, the initial letter of its syllable as

a member of the old key, is placed in small size before and above the initial of the syllable of the new, as ^{m}l, ^{d}s. In the case, however, of an accidental, where the transition is but momentary, a sharpened note changes its syllabic vowel into *e*, and a flattened note into *aw*, spelled *a*, as *fah, fe; soh, se; te, ta*. In the minor mode, *lah* is the keynote; the sharp sixth is called *bah*, and the sharp seventh *se*. The signature of the key of A minor is 'Key C, minor mode.'

For a full explanation of this system see Curwen's *Grammar of Vocal Music*, or the periodical called the *Solfa Reporter*. The advocates of this notation maintain that it possesses advantages over the common system, particularly from the distinctness with which it indicates the keynote and the position of the semitones; the cheapness with which it is printed; and the manner in which, they say, it develops the proper mental effects of notes in key-relationship, and employs them in teaching. It has, however, been objected to by others, from its withdrawal of the direct indication of pitch to the eye which exists in the common notation, from its limited applicability to instrumental music, and from its acquirement not being, like that of the ordinary notation, an introduction to the world of musical literature.

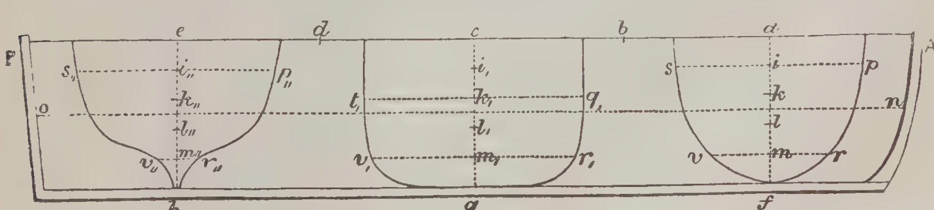
TONKA BEAN, or TONGA BEAN, the seed of *Dipteryx odorata*, a large tree, of the natural order *Leguminosæ*, sub-order *Papilionaceæ*, a native of

Tonka Bean.

Guiana, having pinnated leaves and axillary racemes of purplish flowers. The fruit is an oblong, dry, fibrous drupe, containing a single seed, which has a strong agreeable odour, owing to the Coumarin (q. v.) which it contains, and which is sometimes found crystallised between the cotyledons. Tonka beans are used for flavouring snuff, for which purpose one is carried in the snuff-box; and are put amongst clothes, to preserve them from insects, and to communicate an agreeable odour.

TONNAGE, in regard to ships, is the measure of capacity, the ton being one not of weight, but of cubic content—i. e., 40 cubic feet. Very early in the history of navigation, some scale must have been established by which the relative capacity of different vessels could be determined. In England, there are early laws upon the subject, settling the data upon which the calculation should be made. The present system, called 'New Measurement,' dates from 1835; but the prior system, established in 1719, and now known as O. M. (Old Measurement), still subsists among yachts and some other vessels. The Old Measurement was greatly erroneous, for the actual depth of the ship was not taken into account, but was assumed to be equal to her breadth. The tonnage was then obtained by multiplying together length, breadth, and assumed depth in feet, and by dividing the product by 94. As harbour-dues and such-like taxes were levied according to each vessel's tonnage, it naturally followed under such a system that traders built their ships with as little beam and as great depth as they possibly could. The ships thus became highly dangerous in rough weather, and, moreover, every principle of correct naval architecture was set at nought, to produce deep wooden boxes capable of carrying a maximum of cargo with a minimum of beam. The absurdity of a law by which, in consequence of an inch more beam, a two-decked vessel might appear of greater capacity than a three-decked ship of like length, was so palpable, that many efforts were made at improvement, though without success until 1835.

By the Act of that year, the new system established the depth of hold as a necessary ingredient of the calculation. As, however, the section crosswise of a ship varies so considerably at different points in her keel both in superficies and shape, more than an approximation to her cubic content cannot be attained. To arrive at this approximation, the total length of the upper deck, or, if the ship be not wholly devoted to cargo, of the upper portion of the space for cargo, is taken, and divided into 6 equal parts at the points *a, b, c, d, e*. From the foremost, centre, and aftmost of these points, the depths to the bottom of the hold are measured as *af, cg, eh*. Each depth has to be divided into 5 equal parts; at the fore and after depth, the width inboard of the ship is measured at $\frac{1}{5}$th and $\frac{4}{5}$ths the depth from the top; and the centre-depth at $\frac{2}{5}$ths and $\frac{4}{5}$ths from the top. These lateral measurements at i, $i_{,,}$, $k_{,}$, m, $m_{,}$, and $m_{,,}$, are developed on the plan, and curves drawn representing cross sections of the ship at the given points. All dimensions are sup-



posed to have been taken in feet and decimal parts, and they are thus used in computing the tonnage. The 'length,' *no*, is measured from stem (internal side) to stern-post, at half the height of the centre-depth from the keel. To twice the depth amidships (*cg*), add the depths forward and aft (*af, eh*). The result is the 'sum of the depths.' Add together the two breadths taken at the foremost depth: of the

breadths taken at the centre-depth (cg), add together three times the breadth at $\frac{2}{5}$ths, and twice the breadth at $\frac{4}{5}$ths: of the after-breadths, add together the breadth at $\frac{1}{5}$th, and twice the breadth at $\frac{4}{5}$ths. The sum of these three totals is the 'sum of the breadths.' Having obtained these quantities, the tonnage is approximated to in a somewhat arbitrary manner by the following formula:

$$\text{Tonnage} = \frac{\text{Sum of depths} \times \text{sum of breadths} \times \text{length}}{3500};$$

or, if expressed in terms of the figure:

$$\text{Tonnage} = \frac{\{\, 2cg + af + eh \,\} \ \{\, (ps + rv) + (3t_{,}q_{,} + 2r_{,}v_{,}) + (p_{,,}s_{,,} + 2r_{,,}v_{,,}) \,\} \times no}{3500}.$$

In computing the measurement of a steamer, the same system is followed, but the tonnage of the engine-room (which is supposed to be capable of floating engines and boilers) is deducted from the total to express the tonnage of the ship.

TONNAGE (more properly TUNNAGE) AND POUNDAGE, certain duties on wine and other merchandise, which began to be levied in England in the reign of Edward III. They were at first granted to the crown by the vote of parliament for a limited number of years, and renewed on their expiry. The object of these imposts was said to be, that the king might have ready-money in case of a sudden emergency demanding it for the defence of the realm and the guarding of the sea. Originally fluctuating in amount, tonnage and poundage came to be fixed at 3*s*. on every tun of wine, and 5 per cent. on all goods imported. In the reign of Henry V., they were first conferred on the king for life; and the same course being followed with his successors, the sovereign began gradually to consider them as his proper right and inheritance, and the vote of parliament as but a formality expressive of the popular recognition of his prerogative. Though these duties were not voted to Henry VIII. until the 6th year of his reign, he, notwithstanding, levied them from the date of his accession; and parliament, in voting them, took occasion to blame those merchants who had neglected to make payment. It was, in fact, usual to levy these duties during the period intervening between a sovereign's accession and his first parliament, and this was done by Charles I., as by his predecessors. The Commons, however, in Charles's first parliament, accorded these imposts not for life, but for a year only; and the House of Lords objecting to this departure from previous usages, and rejecting the bill, tonnage and poundage were attempted to be levied by the royal authority alone, a proceeding which raised the opposition of the Commons. Charles was, in 1629, induced to pass an act renouncing the power of levying these or any other imposts without parliamentary sanction. On the Restoration, Charles II. obtained a grant of tonnage and poundage for life; and the same course was followed on the accession of James II. and of William III.; but by three several statutes of Anne and George I. (9 Anne, c. 6; 1 Geo. I. c. 12, and 3 Geo. I. c. 7), these imposts were made perpetual, and mortgaged for the public debt. The Customs Consolidation Act, introduced by Mr Pitt in 1787, 27 Geo. III. c. 13, swept away tonnage and poundage, and all the other then existing changes, and substituted a new and single duty on each article. See CUSTOMS DUTIES.

TONQUIN, the most northerly province of Cochin China (q. v.).

TONQUIN, GULF OF, an arm of the China Sea, bounded by Cochin-China on the W., by China on the N., and by the Chinese province of Quang-tung and the island of Hainan on the E. It is 150 miles in width, and 300 miles in length. The Song-ca and many other rivers fall into the Gulf, and along the coasts are many islands, chiefly, however, small. Extensive fisheries are carried on on the coast; and the fish, besides being largely sold in the interior of the province of Tonquin, are exported in great quantities to China.

TONSILS. See PALATE.

TONSURE (Lat. *tonsura*, a shaving, from *tondeo*, I shave), a religious observance of the Roman Catholic and oriental churches, which consists in shaving or cutting the hair, as a sign of the dedication of the person to the special service of God, and commonly to the public ministry of religion. It is a very ancient usage, and by some writers is represented as of apostolic origin; but that it did not prevail in the early ages is sufficiently plain from the fact with which Optatus upbraids the Donatists of his time (4th c.), of having shaved the heads of certain Catholic priests and bishops in derision. Jerome also, in his *Commentary on Ezekiel*, c. 24, is equally explicit. It would appear that the usage first arose in reference to the monastic rather than the clerical life. Paulinus of Nola, in the end of the 4th, or beginning of the 5th c., alludes to it as then in use among the western monks; and it speedily passed from them to the clergy, the crown-like figure being regarded partly as a symbol of our Lord's crown of thorns, partly as an emblem of the 'Royal Priesthood' of the Christian dispensation. The form of the tonsure was different in different churches, and the varieties of it are of some historical interest. That of the Roman Church, called 'the tonsure of Peter,' consisted in shaving the crown as well as the back of the head, so that there remained a circular ring or 'crown' of hair. This was the form in use in Italy, Gaul, and Spain. In the 'Scottish (or Irish) tonsure,' which was in use in Ireland, in North Britain, and in those parts of Germany in which the Irish missionaries had preached, the entire front of the head was shaved, leaving the front bare as far back as the line from ear to ear. This tonsure was called 'the tonsure of James,' and sometimes of 'Simon the Magician.' The Greeks and other orientals shaved *the entire head.* The supposed derivation of the Irish form of tonsure from the apostolic times, led to its being held both in Ireland and in Britain, as well as other churches of Irish foundation, to be of the most vital importance, insomuch that the introduction of the Roman form was almost the occasion of a schism. Originally, the tonsure was merely a part of the ceremonial of initiation in orders, and was only performed in the act of administering the higher order; but about the 7th c., it came to be used as a distinct and independent ceremonial; and a question has been raised whether it is to be considered as itself an order, and to be added to the list of what are called the 'Minor Orders' (q. v.). The now received opinion of Catholic writers is that tonsure is not an 'order,' but only a 'preparation for orders.'—See Wetzer and Welte's *Kirchen-lexicon*, art. 'Tonsur.'

TONTINE. This term is derived from the name of Tonti, a Neapolitan, who seems to have been the first propounder of a scheme for a financial association of which the prize or prizes were to accrue to the longest liver or livers. Generally, in an association on what is called the tontine principle, a payment is made by each member of the association, and with the capital so formed, an annuity, payable at the same rate until all the lives forming the association are extinct, is bought from some company or individual. This annuity is divided among the members according to age and premium paid by each; and on the decease of any member, the surplus thence arising is divided among the survivors; and on the death of the last member of the association, the total annuity reverts to the source from which it has hitherto emanated. There are, however, various kinds of tontines; and the designation of tontine may, with propriety, be applied to any financial scheme by which it is proposed that gain shall accrue to survivorship. In England, tontines have rarely been resorted to as measures of public finance. The last for which the government opened subscriptions was in 1789.—See Hamilton's *History of Public Revenue*, p. 210. Schemes on the tontine principle seem generally to be acceptable to the public, owing, probably, to the sort of sentimental faith which most persons have in their own prospects of longevity; and to the prudent desire for ease and affluence in old age. The application of the principle by Life Assurance Companies in their mode of distributing 'bonus,' or surplus profits, has long been a subject of controversy among these valuable institutions. It would be impossible here to go into the argument with any degree of nicety. It may, however, be broadly stated as follows: A company formed for the purpose of life assurance means a company in which the members who are lucky in having long life, are to pay for those who are unlucky in dying prematurely. But over and above the net mathematical premium payable by each member of an assurance society, or by each person assured at the risk of a company, a percentage, or 'loading,' as it is technically called, is added, to cover expenses of management and other contingencies. Where the funds of the company or society have been invested with average success, the loading is generally found, at the periodical actuarial investigations, to have been in excess of actual requirements; and the question then arises: How are 'profits,' or, in other words, the overcharges on premiums, to be divided? The question is plainly one of great intricacy. The argument used by the offices favouring the younger policy holders is, that those which favour the older are really acting on a tontine principle, which is the very converse of what ought to prevail in life assurance; on the other hand, it is said that the fulfilment of the insurance contract is provided for by the net premium, and that the distribution of over-payments, as 'profits' really are, is to be determined on principles wholly independent of insurance. See 'Notes on the Early History of Tontines,' by J. Hendricks, in the *Assurance Magazine* for July 1862.

TOOKE, John Horne, a celebrated etymologist and political adventurer, was the son of John Horne, a London poulterer, and was born in that city, June 1736. He was educated first at Westminster and Eton, and afterwards at St John's College, Cambridge, where he took the degree of B.A. in 1758. After spending some time as an usher in a school at Blackheath, he entered the church (to please his father, and strongly against his own wish), and in 1760, became curate at New Brentford. The disgust he entertained for the sacred profession led him to indulge (by way of revenge) in a license of speech and life, which appears to us to have fatally affected the honesty of his character. It is impossible, for instance, to read a passage like the following (from one of his letters to Wilkes), without feeling a deep distrust of the whole man: 'It is true I have suffered the infectious hand of a bishop to be waved over me; whose imposition, like the sop given to Judas, is only a signal for the devil to enter; but I hope I have escaped the contagion; and if I have not, if you should at any time discover the *black* spot under the tongue, pray kindly assist me to conquer the prejudices of education and profession.' When Wilkes (whose acquaintance he had made during a trip to Paris) stood as a candidate for the county of Middlesex, T. zealously aided him, pledging his credit for Wilkes' expenses, and declaring that, 'in a cause so just and holy, he would dye his black coat red;' but he afterwards quarrelled with his dubious associate, and in 1770—1771, the two had a rasping epistolary controversy, which appears to have hugely gratified their enemies. He still, however, continued to meddle in political affairs, and even ventured to encounter (not without success) the formidable Junius. In 1773, he resigned his living at New Brentford, and commenced the study of law, a profession in which he was really fitted by nature to excel. About this time, he rendered some important private service to a Mr Tooke of Purley in Surrey, who designed to make him his heir, but altered his mind, and only left him a legacy of £500. Altogether, however, he is said to have received from this gentleman about £8000, and, in consequence, adopted the surname of Tooke, by which he is now known. In 1775, he was fined and imprisoned in the King's Bench for publishing an advertisement in which he accused the king's troops of barbarously murdering the Americans at Lexington. While in prison, he penned his celebrated *Letter to Mr Dunning*, in which are to be found the germs of his *Diversions of Purley*. It excited a good deal of attention at the time, and even Dr Johnson, who detested T.'s political sentiments, expressed his intention—should he publish a new edition of his *Dictionary*—to adopt several of the 'dog's' etymologies. On his release from confinement, T. made an attempt to gain admission to the bar, but was refused, on the ground of his clerical orders. Soon after, he reverted to political writing, at once the pleasure and the poison of his life, and in a *Letter on Parliamentary Reform*, advocated universal suffrage. In the struggle between Pitt and Fox, he pamphleteered on the side of the former, but soon got to hate Pitt too, as he had learned to hate most other public men. In 1786, appeared his famous *Epea Pteroenta, or the Diversions of Purley*, a work on the analysis and etymology of English words, which, amid much that is erroneous, both in principle and detail, contains still more that is acute, original, and true. In particular, he has demonstrated, says a *Quarterly Reviewer* (No. 14), that 'all words, even those that are expressions of the nicest operations of our minds, were originally borrowed from the objects of external perception.' See Philology. But T.'s passion for politics soon drew him from the calm pursuit of literature into the vortex of public life. In 1790, and again in 1796, he stood as a candidate for Westminster, but was unsuccessful on both occasions. At length, in 1801, the great enemy of rotten boroughs entered parliament for the most notorious rotten borough in England—Old Sarum; but he made no figure there. He died at Wimbledon, March 19, 1812. T. was never married, but had several natural children, to whom he left his property. The best edition of the *Diversions of Purley* is that of Taylor (Lond. 1840).

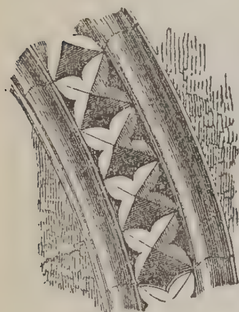
TOOMBUDRA (correctly, TUNGA-BHADRO), an important tributary of the Kistnah or Krishna, rises in the south-west of Maisur (Mysore), and after a north-east course of from 350 to 400 miles, joins the Kistnah, 25 miles below Karnul.

TOON, or **TOONA** (*Cedrela Toona*), a tree of the natural order *Cedrelaceæ*, one of the largest timber trees of India. Dr Hooker mentions one which he measured which was 30 feet in girth at five feet above the ground. The leaves are pinnate, the flowers small, in panicles, with a honey-like smell, the petals erect, and approaching each other so as to form a sort of tube. The tree ascends to the height of 4000 feet on the Himalaya Mountains, and is found to the furthest south of the East Indies. It is sometimes called *Bastard Cedar*. The wood is soft, but is used for furniture. The bark is a powerful astringent, and is used in dysentery, diarrhœa, &c.

TOOTHACHE. See TEETH.

TOOTHACHE-TREE. See ARALIA and XANTHOXYLUM.

TOOTH-ORNAMENT, much used in the Early English style.



Tooth-ornament.

TOP, in a Ship, is the platform at the head of each lower-mast. It is supported on the trestle-trees and cross-trees, and serves to give a wider base to the top-mast shrouds. It is also used for working the upper sails. In a well-ordered ship, there is a captain and crew for each top. Formerly, in vessels of war, the top was fortified with hammocks all round, and in action was made to do duty as a sort of redoubt, whence a fire of small-arms, or even light swivel-guns, was poured upon the deck of the enemy.

TOPAZ, a mineral, ranked by mineralogists amongst Gems (q. v.), and the finer varieties of which are much valued both for their lustre and the beauty of their colours. It is composed chiefly of alumina and silica, the former, in general, more than 50 per cent. of the whole, with fluoric acid, and usually a little oxide of iron. It is found generally in primitive rocks, and in many parts of the world. A crystal 19 ounces in weight was found in the Cairngorm Mountains in Aberdeenshire, Scotland; and fine topazes are sometimes found in that part of Scotland, in Cornwall, and in the Mourne Mountains in Ireland. Fine topazes are found in Ceylon, but those most prized by jewellers are generally from Brazil. The finer varieties of T. are in general found either crystallised, or as small rolled masses, which may have been formed from crystals, in alluvial soil. T. is either colourless, or red, blue, green, or yellow, in great variety of shades. Its crystals are rhombic prisms, generally terminated by four-sided pyramids, but often variously bevelled and acuminated. The prisms are finely striated. The cleavage parallel to the base of the prism is easy. The specific gravity is about 3·5. The lustre is vitreous. T. is translucent or almost transparent on the edges. It is harder than quartz. It is rendered very electric by heat or friction, and by this property a T. may at once be distinguished from a diamond or ruby, for which otherwise, when cut and set, it might readily be mistaken. A coarse variety of T., called *Pyrophysalite*, occurs near Fahlun, in Sweden, which is not crystallised. It is greenish white. When reduced to powder, it can be used as emery for grinding and polishing.—T. derives its name from the *Topazion* of the ancients, which, however, seems to have been a totally different mineral.

TOPE (*Galeus canis*), a small species of shark, of the family *Galeïdæ*, which has two dorsal fins and one anal, spout-holes, and the eyes furnished with a nictitating membrane, the first dorsal situated over the space between the pectorals and ventrals. The T. is very abundant on the southern coasts of Britain, but becomes more rare towards the north. The name T. is said to be originally

Tope (*Galeus canis*).

Cornish. Other local names are *Miller's Dog* and *Penny Dog*. It attains a length of about six feet. The T. is extremely troublesome to fishermen, robbing their lines of the fish which are attached to them, and biting off the hooks, or, if it happens to be itself hooked, often winding the line round its body in many coils and with tangled knots.

TOPE is the vernacular name of Buddhistic monuments intended for the preservation of relics. In Ceylon and elsewhere, they are also called *Dagops;* and another of their designations is *Chaitya*. The difference between these terms results from their meaning. Tope is the Pâli *thûpa*, and the Sanscrit *stûpa;* it means therefore literally 'accumulation,' and conveys a sense analogous to that of the Latin *tumulus*. *Dagop* is a corruption of *dhâtu-gopa*, i. e., relic-preserver; and *Chaitya* applies generally to objects of worship, as images, temples, sacred trees, &c. *Tope* is therefore the name of those monuments in regard to their shape; *Dagop*, in regard to their purpose; and *Chaitya* the general term. Though the shape of the topes underwent many changes according to time and locality, it is possible to distinguish its oldest type from its later development. The oldest topes are in the shape of cupolas, generally spherical, but sometimes elliptical, resting on a cylindrical or quadrangular, or polygonal base, which rises either in a straight or inclined line, or in terraces. The top of the cupola, surrounded by a balcony of pillars of a peculiar kind, is crowned by a structure generally quadrangular, but sometimes in the shape of a reversed pyramid of a few steps; and over this structure is a roof in the shape of an extended parasol (Sanscrit, *chhattra;* in Pâli, *chatta*). This was the form, for instance, of the topes of Sanchi, of the dagops of Ceylon, and the oldest monuments of this kind in the Punjab and Afghanistan; though in most of them the parasol, being of wood, is either completely destroyed, or merely recognisable in its fragmentary condition (see art. BUDDHISM, where in the section of the cave-temple at Karli, the tope is seen still surmounted by the wooden umbrella). The cupola was sometimes

ornamented with more than one parasol; in some of the topes of Sanchi there are three, and even five parasols side by side, the middle one exceeding the rest in height. The different arrangement of these parasols, especially when their number increased,

Fig. 1.—View of principal Sanchi Tope.
(From Fergusson's *Hand-book of Architecture.*)

led to a different shape of the topes, such as occurs, for instance, in China and Tibet. This arrangement consists in placing them one *over* the other; and not only three or five, but even seven, nine, or more are so placed. The height of the structure thus became naturally greater than it originally was, and the topes, instead of having the character of cupolas, now assumed that of pyramids resting on a cupola

Fig. 2.
Rock-cut Tope at Ajunta (from Fergusson), in which the three umbrellas have become a spire.

base, the parasols gradually giving way to a real pyramidal form. In some monuments of this class, however, the cupola was placed above, when the base consists in round or quadrangular towers rising in a spiral form, or in several stories. The Chinese, on the contrary, rejected the cupola altogether, and merely retained the succession of parasols extended one over the other, converting them into a many-storied tower; and the same is the case with the topes of the Mongols, the *Ssuvurghans*, which are pyramids erected on a low quadrangular base. The top of the pyramidal topes always carries some metal ornament, frequently gilt, resembling a parasol, or a needle, or a trident, or a rising flame. The height of these buildings varies from a few feet to 300, and even more; there are also topes of a few inches only, but they serve merely as ornaments in temples or buildings, or as symbols of the real topes. If erected in cave-temples, the tope generally stands at the end of a long hall especially cut out for it, but sometimes also in the sanctuary of the cave-temple itself; if erected over-ground, it stands always in the vicinity of a temple or convent. In the interior of the tope is the cell or chamber (*dhâtugarbha*) where the box containing the relics and 'the seven precious things' was placed. This cell consists of six slabs of stone, firmly closed after the box with the relics, &c. had been placed in it; and it was immured into the tope after its structure had, in the course of building, attained a certain height; the building then being brought to its completion, so that the cell enshrining the relic was enclosed on all sides with solid brickwork. The 'seven precious things' referred to, with which the relics were ornamented, are differently enumerated; according to one account, they are gold, silver, lapis lazuli, crystal, red pearl, diamond, and coral; others mention ruby and emerald; and others, again, omit gold and silver. In several cells which have been opened, the box contained, besides the relics, precious stones of various kinds, golden ornaments, and coins; and the box itself generally consisted of an outer casement of stone, clay, or bronze, which enclosed a silver cylinder, and within this, a golden cylinder, which was the real receptacle of the relics. Both cylinders had generally a convex lid, representing the shape of the cupola, and the box exhibited inscriptions commemorating the name of the saint to whom the ashes or other relics contained in it had belonged. It seems that there are also topes which had the relics placed, not within, but under them—or, in other words, in the ground on which they were erected; for, in some which were opened, neither a cell nor any relic was found; and though it is possible that such monuments were merely erected in commemoration of some personage, there are, on the other hand, accounts which relate that relics were also placed under the dagops. Whether these accounts be correct, it is at present impossible to say, as no foundation on which such dagops stand has as yet been explored. It has been supposed by some authors that the topes contained some secret passage leading to the relic-cell, known only to the priests or the initiated, who thus might gain access to the relics; for legends relate that during night such relics occasionally shed light, and that some pious king was deigned worthy of being favoured with their sight; but none of the topes hitherto explored—and some of these are of the greatest dimensions—yielded any confirmation of this theory; they proved to be nothing but solid masses of brick and stone, without any chambers or passages—merely containing the relic-cell, of generally one foot in diameter. That the cupola of the topes was intended to represent the water-bubble, the Buddhistic symbol of the hollowness and perishability of the world, is borne out by a legend in the *Mahâvans'a* (q. v.). The purport of the parasol may seem more

doubtful; but as the parasol is the emblem of Hindu royalty, and as S'âkyamuni, himself the son of a king, replied to the question how he wished to be buried, by answering: 'Like an emperor,' it is not unlikely that the parasol of the topes was intended to imply the royal dignity possessed by a Buddhistic saint. When the topes became pyramids or towers consisting of terraces and stories, the number of the latter had likewise a symbolical import. Thus, only the topes of the most accomplished Buddhas had thirteen terraces, to shew that these Buddhas had passed beyond the twelve causes of existence; three terraces imply the three worlds—the world of desire, that of form, and that of absence of form; five, the five steps of Mount Meru; and so on.—See C. F. Koeppen, *Die Religion des Buddha* (Berlin, 1857), vol. i. p. 533, ff., and the works quoted there.

TOP-GALLANT, in a Ship, the name applied to the third mast or sail above the deck, i. e., to the mast and sail next above the topmast and topsail respectively.

TO'PHANÉ (correctly, TOP-HANEH), a suburb of Constantinople, forms a continuation of Galatea along the northern shore of the Bosporus. See CONSTANTINOPLE.

TOPICS (the Greek term *topike*, from *topos*, a place) was the name given by the Greek and Roman rhetoricians and grammarians to the art of discovering arguments. It consisted in the eliciting out of the series of particulars certain general conceptions and propositions, which, in the elaboration of oratorical discourses, served as guides in the invention and choice of suitable arguments. Any one such general conception was called in Greek *topos;* in Latin, *locus communis* (a 'common place'). The Greeks bestowed much attention on this art; among the Romans, Cicero composed *Topica*, and various other treatises of a kindred nature. During the middle ages, it was proposed to apply it to the whole circle of human knowledge, and even to the solution of the most difficult intellectual problems; but, in general, these efforts only resulted in empty exhibitions of mental vivacity (*jeux d'esprit*); and in modern times, the so-called 'art' has sunk so low, that by the term 'topic' one understands nothing more than a theme or subject for discussion and talk.

TOPKNOT, the popular name of some small fishes of the same genus with the Turbot (q. v.) and brill. MULLER'S T. (*Rhombus hirtus*) is not uncommon on some parts of the British coast, particularly the west coast of England. BLOCH'S T. (*R. punctatus*) is more plentiful in more northern parts. They are very similar, brown and mottled with very dark brown or black on the upper surface, white below. They live among rocks, where they are not easily distinguished by the eye from the sea-weed. Although very delicate fish, they are little regarded, the largest being seldom more than 7 or 8 inches in length. The breadth is about half the length.

TÖ'PLITZ, or TEPLITZ, a watering-place of Bohemia, perhaps the most celebrated of the German spas, is pleasantly situated on the Saubach (Pig's Stream), 16 miles north-west of Leitmeritz. The chief building is the palace of Prince Clary, to whom the town in great part belongs; and behind this building are a park and gardens, which are the principal places of resort. Within their limits are the theatre and the Gartensaal, the latter of which serves the purposes of reading, dining, and ball room. On the hill behind the palace is the Schalckenburg, a sort of tavern, built in imitation of a castle, and which commands a wide view from its prospect-tower. The baths are supplied from 11 hot alkalo-saline springs, the chief of which has a temperature of 120° F. They are taken exceedingly hot, and have great virtue in restoring persons afflicted with gout, rheumatism, &c. Pop. of T., 4000, which rises to 10,000 during the months of July and August.

TOPO'GRAPHY is literally a description of places (Gr. *topos*, a place), as rivers, hills, woods, but more especially cities, roads, bridges, streets, and even particular buildings. It differs from ordinary geography only in being more special and minute. Thus, we have topographical descriptions of counties, provinces, and kingdoms, excellent specimens of which are Lewis's *Topographical Dictionary of England*, and Murray's *Hand-books* of English counties and continental kingdoms.

TOPOGRAPHY, MILITARY. Among the first necessities of a military commander is a thorough knowledge of the physical conformation, the obstacles, and the resources of the country in which he has to operate. It frequently happens that the field of warfare is one of which no careful survey is procurable. It devolves, then, on the officers of the staff to make their chief acquainted with all the particulars he requires; hence, topographical drawing is made a principal ingredient in the course of study at the Staff College. These surveys devolve, in the field, on the quartermaster-general's department. An officer of this service is expected to traverse a country with rapidity, to measure distances by eye or intuition, to note them roughly down as he rides, to obtain a rough knowledge of hills and valleys, of roads and ravines, rivers and the means of crossing them. He must at the same time make himself acquainted with the means of sustenance produced by the country, with the feelings of the people—whether friendly or hostile—with the transport which can be drawn from the villages, with the position and strength of fortified places, and, in short, with every particular which can be of service to his commandant. His reconnaissance finished, not without fatigue and danger, he is expected to sit down and produce an eye-map, or a full report of all he has seen and heard.

The *Topographical Department* is a department of the War Office under the 'Director of Surveys,' who is an officer of engineers. It comprises the 'Ordnance Survey,' which is charged with the various national surveys; and the Topographical Dépôt, a collection of maps, plans, descriptive-books, and journals of staff-officers from all parts of the globe. The officers of this dépôt always try to keep their information posted up to the latest date, that, on an army taking the field, the general may at once be put in possession of a competent knowledge of the country he is to pass through or occupy.

TOP-SHELL. See TROCHIDÆ.

TOR (Celtic), 'a projecting rock, is found in the names of Mount Taurus and the Tors of Devonshire (Yes Tor, Brent Tor, &c.) and Derbyshire (Mam Tor, Chee Tor, &c.). The higher summits of the *Tyr*-ol are called Die *Taur*-en.'—Taylor's *Words and Places.*

TORBANEHILL MINERAL, a name sometimes popularly given to a mineral substance also known as BOGHEAD COAL, found on the lands of Boghead and Torbanehill, near Bathgate, Scotland, and celebrated for its value as a source of Paraffin Oil or Naphtha (q. v.), of which it yields a much greater quantity than any other coal or shale found

in Britain. Large quantities are exported to the continent of Europe. A famous litigation took place in 1853 concerning this mineral, between a landlord and the lessees, which turned partly on the question, whether it ought to be regarded as a coal or a shale, a point on which opposite opinions were expressed by eminent men of science.

TORCE, or WREATH, in Heraldry, a garland of twisted silk, by which the crest is joined to the helmet. A crest is always understood to be placed on a torce, unless where it is expressly stated to issue out of a coronet or chapeau.

TO'RGAU, a town of Prussia, and a fortress of the second rank, stands on the left bank of the Elbe, 70 miles south-south-west of Berlin, and 12 miles north of the frontier of the kingdom of Saxony. The river is here crossed by a bridge 500 paces in length, and supported upon 15 stone piers. Among the public buildings are the castle, now used as a barrack and magazine, and comprising a church consecrated by Luther in 1544; a town-church, with pictures by Cranach; a gymnasium, with 300 pupils, instructed by 13 professors. Hops and vegetables are largely raised in the vicinity. A battle was fought here in November 1760, in which Frederick II. of Prussia defeated the Austrians. Pop. 10,762.

TO'RGET, a small island off the north-west coast of Norway, in lat. 65° 30′ N. It serves as a landmark to sailors, is the haunt of numerous waterfowl, but is chiefly noteworthy for its lofty rock called Torghatten (the Hat of Torget), which rises to the height of 756 feet above sea-level, and is pierced right through, near the top, by a cave or passage 80 feet wide, and 1300 feet long.

TORLONIA, a princely Roman family, remarkable for their wealth, and for their extraordinarily sudden rise from the very lowest condition, trace their origin to a poor 'cicerone,' Giovanni T. (born in 1754), who hung about the Piazza di Spagna in Rome, and gained a precarious living by shewing visitors over the Colosseum. By steadiness and honesty, he obtained a reputation in his profession, became afterwards an agent of the French emissaries who were sent to excite the Roman populace to revolution, and on the failure of this project was left with considerable funds in his hands; he afterwards married a widow of means, and became a merchant, gradually rising, by dint of great intelligence, keen foresight, and enterprise, to the position of a stockbroker, usurer, and money-dealer; and by acquiring mortgages over the properties of the impoverished Roman princes, and by various other happy ventures, ultimately amassed an immense fortune. He was made a grandee of Spain, and Duke of Bracciano by the pope. His three sons have allied themselves with princely families of the highest rank; the two younger (the eldest succeeding to the dukedom) carry on their father's business, and are rapidly taking rank among the extensive landed proprietors of Central Italy.

TO'RMENTIL (*Tormentilla*), a genus of plants of the natural order *Rosaceæ*, sub-order *Potentilleæ*, differing from *Potentilla* (q. v.) only in the 4-parted calyx and corolla, and now united with it by many botanists. The COMMON T. (*T. officinalis*, or *Potentilla tormentilla*) is a very common plant in moorish and heathy places in Britain and throughout great part of Europe. It has a large woody root, which has long been officinal, being an agreeable and efficacious astringent, useful in diarrhœa and other complaints; and which contains tannin, gum, and a red colouring matter, not soluble in water, used by the Laplanders for staining leather red. The leaves are ternate, the leaflets lanceolate, and inciso-serrate; the stems ascending and

Tormentil (*Potentilla tormentilla*).

forking, the flower-stalks axillary and terminal and the flowers yellow.

TO'RMINA is the technical term for *griping* pains in the belly.

TORNA'DO. See WHIRLWIND.

TO'RNEA, a river, important as forming part of the boundary-line between Russia and Sweden, rises in Lake Tornea, in Sweden, and flows south-east and south between Russia and Sweden, entering the Gulf of Bothnia at its northern extremity, after a course of 250 miles. At its mouth is the small town of Tornea (q. v.).

TORNEA, a town in Finland, situated in 65° 50′ N. lat., and 24° 10′ E. long., on the peninsula of Svensar, at the mouth of the Tornea, in the government of Uleaborg. The pop., which is about 800, is principally engaged in the exchange-trade with the more northern and scantily-inhabited districts of Finland and Sweden, of which T. is the active centre, as the most northerly town in the Russian Empire; deals, salt-fish, tar, hemp, reindeer skins and other peltries being brought to T., to be exchanged for tobacco, spirits, manufactured goods, &c. T. is often visited in summer by travellers, anxious to witness the singular spectacle of the sun remaining above the horizon both night and day at the summer solstice. T. was several times taken by the Russians from Sweden before its final cession at the Peace of Fredrickshamm, in 1809, when it was ceded, together with the whole of Western Finland, to Russia.

TO'RO, or TORRO, an ancient but decayed town of Spain, in the modern province of Zamora, stands on the right bank of the Douro, 21 miles east of Zamora. It contains numerous religious houses, most of which have been allowed to fall into a state of decay; there are brandy-distilleries and brick and tile works. Pop. 7000.

TORO'NTO, the capital city of the province of Ontario, stands on the north shore of Lake Ontario, in lat. 43° 39′ N., long. 79° 23′ W., 165 miles from Kingston, and 323 miles from Montreal. It is over two miles in length between east and west, is bounded on the S. by the Bay of Toronto, a spacious inlet of Lake Ontario, and is a mile and a half broad from south to north. The scenery of the vicinity is somewhat tame, and the situation of the town is low and flat, the most elevated quarter—the Queen's Park in the west, containing the university, observatory, and handsome private residences—being only from 100 to 200 feet above the level of

the lake. The harbour or bay, about five miles long and a mile in width, is formed by a curving spit of land running into the lake in a south and west direction to the distance of three miles. It is capable of accommodating the largest vessels that navigate the lakes, and is defended at the entrance by a fort, which was thoroughly repaired in 1864 by the imperial government, and mounted with the most efficient modern ordnance. T. has much the appearance of an English town, and is distinguished for the number of its churches—many of which are surmounted by handsome spires. The principal are St James's Cathedral (Anglican), a noble edifice in Early English, erected in 1852; St Michael's Cathedral (Roman Catholic); Knox's Church, with a beautiful spire, and Cooke's Church, both belonging to the Free Church; and the Unitarian chapel. T. is the fountain-head of the Canada school-system, and its educational institutions are numerous and well appointed. The university, charmingly situated in the well-wooded Queen's Park, was inaugurated in 1843, and is attended by 250 students; Trinity College has about 100 students; and the Upper Canada College has 200. There are also the Normal and Model Schools, in the first of which teachers exclusively are trained. Attached to the university is the observatory. There are many benevolent institutions, as hospitals, asylums, &c. Osgood Hall, an elaborate and beautiful building, is the seat of the superior law-courts of Upper Canada. T. is a station for five railways, the Grand Trunk, running east and west, the Great Western, the Northern, the Toronto and Mipissing, and the Toronto, Grey, and Bruce; while, during open navigation, magnificent steamers ply in all directions on the lake. Cabinet-ware and iron rails are manufactured, and foundries, distilleries, and flour-mills are in operation; the exports are manufactured lumber, flour, wheat, and other grain. In 1872, the exports amounted in value to 2,201,814 dollars, the imports to 13,098,133 dollars. Forty-one newspapers and periodicals are published in Toronto, viz.: 4 daily, 15 weekly, 5 semi-monthly, 15 monthly, 1 quarterly, and 2 annually. The city is well supplied with water and lighted with gas. Real and personal property (1872) $32,644,612. Pop. in 1817, 1200; in 1830, 1677; in 1852, 50,763; and in 1881, 86,415.

The name T. is supposed to be of Indian origin, but the meaning of the word appears to have been lost. The town was founded in 1794 by Governor Simcoe. It was incorporated in 1834, was burned by the Americans in 1813, and suffered severely in the insurrection of 1837, on which occasion it was the headquarters of the rebellion, as also from fire in 1849.

TORPE'DO, a genus of fishes of the order *Raiiæ* (see RAY), and family *Torpedinidæ*. All the

Torpedo (*Torpedo vulgaris*).

Torpedinidæ were formerly included in this genus, itself originally formed from *Raia*; but it has been divided into a number of genera, as *Torpedo*, *Narcine*, *Astrape*, &c. The *Torpedinidæ* have a short and not very thick tail, cylindrical towards the end, keeled on the sides. The disc is rounded, and has neither scales nor prickles. The most remarkable characteristic, however, is the galvanic battery, which all the species possess, and which is described and figured in the article ELECTRICITY, ANIMAL. The name T. is very commonly extended in a popular sense to all the *Torpedinidæ*. Two species of T. are occasionally found on the southern coasts of England—*T. vulgaris* or *marmorata*, which sometimes attains a large size, weighing 100 lbs.; and *T. Nobiliana*, which is apparently more rare. They are readily distinguished by the spiracles behind the eyes, which are round and fringed at the edges in the former, oval and perfectly smooth in the latter. These and other species are found more plentifully in the Mediterranean, and the *Torpedinidæ* generally belong to the warmer seas. The popular names *Numb-fish*, *Cramp-fish*, and *Cramp Ray* are given to torpedos by English fishermen. The electric shock which a large T. gives when seized is so severe, that no one who has experienced it desires to experience it again.

TORPEDO. During the war between Great Britain and the United States in 1812—1814, this name was applied to certain mysterious boats invented by Fulton and other Americans for the purpose of navigating beneath the surface of the water, and injuring the bottoms of hostile vessels. In those days of hand-to-hand naval war, these designs (which, by the way, were failures) were looked upon as little less than diabolical. The progress of destructive weapons during half a century has removed this aversion, and nations do not scruple now to employ similar unseen agents for offence and defence. The modern torpedo is really a stationary bomb-shell, intended to explode under the bottom of an enemy's ship. The weapon was first used by the Russians in the Baltic in 1854; and in the American War of Secession of 1861—1865 it was employed extensively, and often successfully. The damage effected by a torpedo exploding beneath a ship is very great; and although the failures are very frequent by the explosion happening at a wrong moment, the danger from torpedoes is considerable in fact, and far more in apprehension, for sailors naturally dread navigating waters where destruction lurks at unknown points concealed from view. There are several varieties of torpedoes, but they may be divided into two classes: those which are self-explosive on a ship touching them, and those which are dependent on an electric current supplied from the shore. The second are the safest for friendly vessels; but they are rather uncertain in action, and can only be employed at a moderate distance from the shore. The first are more certain in action, as they can only explode on a ship being somewhere in contact, but they attack indiscriminately friend and foe.

A torpedo of the self-acting class is shewn in fig 1: *abc* is a hollow iron cone, water-tight, with a ring at *b* by which to anchor it. The upper part, B, is left empty, for the sake of buoyancy, while the lower end, A, is filled with gunpowder, the charge varying from 100 to 300 lbs. At the top of the powder is an iron case, C, filled with lime, and in it a tube of thin glass, D, containing sulphuric acid. The upper part of the glass tube is enveloped by the ringed end of the iron rod, E, which passes through the top of the torpedo, and some distance above it. This rod moves on a joint at F; and to make it more sensitive, while at the same time extending the area of operation, the horizontal rods, G, called feelers, are attached rigidly to its upper extremity

When a ship impinges on the feelers, G, the rod E is deflected from the perpendicular; the ring at

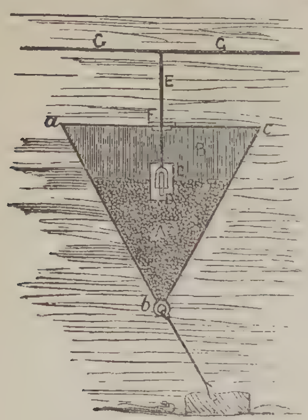


Fig. 1.

the lower end breaks the glass tube D; the acid acting chemically on the lime, generates great heat, and explodes the powder.

Fig. 2 shews an electric torpedo. As before, A is the powder, B empty. Two wires are laid along the

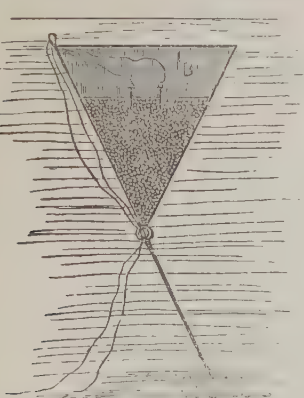

Fig. 2.

bottom of the water from the shore, passed through the ring below the cone, and brought in at the top to two knobs on the upper part of the powder-keg. Between these, a piece of platinum wire passes through a sensitive cartridge. As soon as the circuit of electricity is completed on shore, the platinum becomes incandescent, and the explosion takes place. To ascertain the right moment at which to complete the circuit, elaborate observations are necessary from the shore, as in fig. 3. Two observers at A and B direct their attention to two distant marks, *a* and *b* respectively. At each station (A and B) there is a break in the circuit of the wire, *ccc*. At the point C, where the lines of observation intersect, the torpedo is carefully moored. This point is, of course, selected as one over which, from the run of the channel, there is a strong probability that the ship to be destroyed will pass. Now, let an enemy be passing up the channel. The moment A sees him on his line A*a*, he completes the connection at A, and keeps it complete while any part of the vessel is on the line. Similarly, B completes while the ship is over the line B*b*. If these connections subsist at the same moment, the torpedo is blown up, and the chances are the ship will b over it at the same instant. An ingenious application of the electric current to a self-acting torpedo has been proposed. One wire comes from the battery to the torpedo, but is only left unbroken when an enemy's ship is near the required spot. This wire is led down through a platinum wire in the powder to the outside of the case C (fig. 1), in

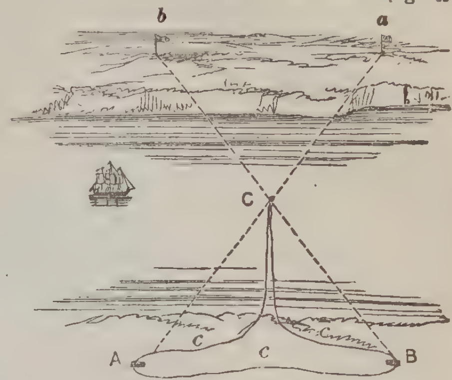

Fig. 3.

which there is neither lime nor acid. When the rod E is deflected, its lower end touches the case, completing the electric connection with the water, and by means of the water, completing the circuit, when the incandescence of the platinum (as in fig. 2) causes the explosion. This instrument has the double advantage of being fired by the ship's contact, and at the same time of being rendered harmless when desirable merely by disconnecting the wire from the battery. The first and last of the torpedoes described above present great difficulties when it is sought to remove them.

TO'RQUAY, a celebrated watering-place on the south coast of Devon, occupying a retired and capacious cove on the north side of Tor Bay, 23 miles from Exeter, and about 210 from London. The name is derived from the Celtic 'Tor' (q. v.), a hill, which occurs in the appellations of the neighbouring peaks of Dartmoor (Hey Tor, Rippon Tor, &c.), and thence is given to the bay, to which these serve as a landmark, and to the ancient parish of Tor Mohun or Tormoham, in which T. is situate. The monastery of Tor Abbey was founded in the 12th c. by Reginald Brewer, then the lord of the manor. Some remains of the original monastic building are still found on the site. The town of T. is of recent origin, and affords a striking instance of rapid growth. The bay is noted in history as the place where William of Orange landed in 1688, and was often used as a naval rendezvous during the war with France; but till the beginning of the present century, T. was little more than an assemblage of fishermen's huts. About that time, the advantages of its climate—which are a peculiarly sheltered position, an equable temperature, and freedom from fogs—caused it to be resorted to by consumptive patients; and it soon attained a European celebrity, which is still almost unrivalled. The romantic hills and valleys of Tormohun and its environs are being rapidly overspread with villas, gardens, terraces, and rows of smaller dwellings. The original parish has been divided into four, and possesses six (English) churches, one Roman Catholic, one Scotch Presbyterian, and numerous dissenting chapels. A stone pier was built in 1803, and the port is resorted to by

colliers and small traders. The present high-road to Newton-Abbot was made about 1825; and the first station of the South Devon Railway was opened in 1845. The geological formation consists mainly of a range of transition limestone cliffs in strata much contorted, forming an excellent building material; and in some places, as at Petit Tor, presenting beautifully-tinted marbles, which are extensively worked. The limestone gives place at some points to Old Red Sandstone, which gives its predominating colour to the soil, and to argillaceous shale in beds of considerable thickness. The scenery is of the most varied and picturesque description. Besides the mildness of the winter, the vicinity of the sea in front, and of Dartmoor in the rear, greatly moderates the summer climate, so that while the mean winter temperature is 44°, being 3° above that of Greenwich, that of the summer is only 55°, nearly 1° below that of Greenwich. The pop. has increased from under 1000 in 1801 to over 32,900 in 1881. Kent's Cavern, discovered in 1824, and the Brixham Cave, discovered in 1858, are rich in fossils, and are among the earliest places in the kingdom in which prehistoric human remains have been found.

TORQUES (Celtic, *torc;* Lat. *torqueo*, I twist), a species of gold ornament, meant to be worn round the neck, which was much in use in ancient times, both among Asiatic and North European nations. It consisted of a spirally-twisted bar of gold, bent round nearly into a circle, with the ends free, and terminating in hooks, or sometimes in serpents. These ornaments seem to have formed an important part of the wealth of those who wore them, and of the plunder obtained by the Roman conquerors from a Celtic or oriental army. A monument erected to a Roman soldier not unfrequently specified the number of torques that had been conferred on him. Numerous examples of the torques have been dug up in Great Britain and Ireland, as well as in France, and are to be found in different archæological collections. Both in Europe and in Asia, the torques resembled one form of Bracelet (q. v.) on a larger scale.

TO'RRÉ DEL GRE'CO, a city of Southern Italy, at the base of Vesuvius, 7 miles from Naples. Its pop., which once numbered 15,000, is, since the last two eruptions, reduced to 5477 (1861). The town is always new, being from time to time destroyed by the lava, and always raised again from its ruins, by the attachment of its inhabitants to their native soil. The soil is fertile, producing fruit and wines similar to those of Greece. Its inhabitants are engaged in the tunny, oyster, and sardine fisheries. Mention is made of the town under its present name (the origin of which is unknown) as early as 1324 A. D. It suffered much in the eruption of 1631, and in that of 1795 it was totally destroyed. T. del G. rose again from its ruins; and although it suffered in subsequent eruptions, especially in those of 1804 and 1822, it has never again been entirely destroyed by the lava.

TO'RRÉ DELL ANNUNZIA'TA, a fortified town of Southern Italy, 13 miles south-east of Naples, stands on the southern base of Mount Vesuvius, 13 miles south-east of Naples. Its chief features are the barracks, the royal arms-factory, and the thermal springs on the sea-shore, close to the town. A fishery and an active coasting-trade are carried on. Pop. 15,500.

TO'RRES STRAIT lies between North Australia and Papua or New Guinea, in lat. 9° 20′—10° 40′ N.; and long. 142° 30′ E. The channel is about 80 miles in width; and its navigation, though practicable, is rendered dangerous and difficult by the innumerable shoals, reefs, and islands with which it is strewn. It was discovered by Torres in 1606.

TO'RRES-VE'DRAS, a town of Estremadura, kingdom of Portugal, on the left bank of the Sizandro, about 30 miles north of Lisbon. It has a pop. of about 3300, and carries on some trade in wine; but derives its reputation solely from having given name to those famous lines of defence within which Wellington took refuge in 1810, when he found it impossible to defend the frontier of Portugal against the French armies; and from which, in the year following, he issued on that career of slow and hard-won victory, which ended in the expulsion of the French from the Peninsula. The *first*, or outermost of these lines, extending from Alhandra, on the Tagus, to the mouth of the Sizandro, on the sea-coast, and following the windings of the hills, was 29 miles long; the *second* (and by far the most formidable) lay from 6 to 10 miles behind the first, stretching from Quintella, on the Tagus, to the mouth of the St Lorenza, a distance of 24 miles; the *third*, situated to the south-west of Lisbon, at the very mouth of the Tagus, was very short, being intended to cover a forced embarkation, if that had become necessary. The entire ground thus fortified was equal to 500 sq. miles.

TORRICELLI, EVANGELISTA, a celebrated Italian mathematician and philosopher, was born at Piancaldoli in the Romagna, Italy, October 15, 1608. He was brought up by an uncle who resided at Faenza, and who put him under the tuition of the Jesuits. When 20 years old, he was sent to Rome, and there devoted himself to mathematical studies. Galileo's theories on force and motion, which had been published a short time before, especially engaged his attention, and led to his publishing a *Trattato del Moto* (1643), a meritorious work, but containing few new discoveries of consequence. The publication of this work led to his being invited by Galileo to visit him; and on the old philosopher's death, three months afterwards, he was appointed to succeed Galileo in the chair of Philosophy and Mathematics at Florence. Here he resided till his death in 1647. The discovery which will preserve T.'s name through all ages was the interpretation of the previously known fact, that water will rise in a suction-pump only to the height of about 32 feet. The fact that water *could* be raised in a pump was expressed by the empirical law, that 'nature abhors a vacuum,' and after the limit of 32 feet was ascertained, the law was modified accordingly by Galileo. T., wishing to perform this experiment more conveniently, employed mercury, and found that nature's abhorrence of a vacuum varied for different fluids, and was represented by a column of fluid in height inversely proportional to its specific gravity; here, then, was an additional fact of importance, containing the clue to the mystery, and T. was not long in hitting on the idea that the column of fluid was sustained by the pressure of the atmosphere on the open surface of fluid. See BAROMETER. T. also effected the quadrature of the cycloid, but in this was anticipated by Roberval.

TO'RRINGTON, a municipal borough and market-town of the county of Devon, on an eminence sloping to the Torridge, 10 miles south-south-west of Barnstaple. The inhabitants, who slightly increased in numbers between the years 1861 and 1871, are employed for the most part in agriculture and glove-making; but the industry is inconsiderable. Pop. (1881) 3445. The name of T. emerges frequently during the great Civil War; and the capture of the town by Fairfax in 1646, on which occasion the church, with 200 prisoners, and

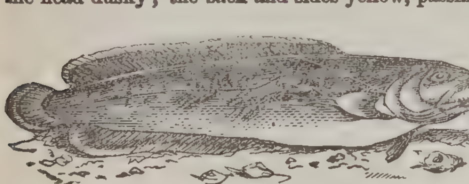
those who guarded them, were blown into the air by gunpowder, proved fatal to the king's cause in the west.

TORSHO'K, one of the most ancient towns in Russia, in the government of Tver, stands on the Tverza, in an undulating district, 309 miles south-east of St Petersburg. Leather and malt are the most important branches of manufacture; but the gold and silk embroideries of this town are well known throughout the empire, and obtained much celebrity at the London Exhibitions of 1851 and 1862. There is an extensive trade in corn, which the merchants of T. purchase in the neighbouring districts and at the landing-places of the Lower Volga, and thence transport to St Petersburg by water. Much of this corn is ground at T., and the flour exported. The town was founded in the 11th century. Pop. 16,240.

TO'RSION is a method of common application in surgery for the purpose of checking arterial hæmorrhage in certain cases. The wounded vessel is drawn out and fixed by a pair of forceps a quarter of an inch from the end; the end of the artery is then twisted round till it will not untwist itself. It is especially useful when there are many small arteries wounded in an operation, as, for example, in the extirpation of a large tumour.

TORSION-BALANCE (Lat. *torsio*, twisting) is an instrument first invented by Coulomb, in which the force exerted by a twisted thread or filament to recover its original position, is made the means of measuring small degrees of electrical and magnetical attraction. See ELECTRICITY, fig. 9. It has also been used in determining the mass and density of the earth. See EARTH.

TORSK or, by corruption, TUSK (*Brosmius vulgaris*), a valuable fish of the family *Gadidæ* (q. v.), abundant in the northern parts of the Atlantic Ocean. The genus is characterised by a single long dorsal fin, and by having the vertical fins separate. The T. is from 18 inches to 2 feet, rarely 3 feet long; the head small, the body moderately elongated, one barbule under the chin, the dorsal and anal fins distinct from the tail, although separated from it by a very short interval; the tail rounded; the head dusky; the back and sides yellow, passing



Torsk, or Tusk (*Brosmius vulgaris*).

into white on the belly. It lives in deep water, approaching the land in shoals only at the spawning-time, which is very early in the year. It spawns among the sea-weed of the coast. It is caught in the same manner as cod, ling, &c.; and although rather firm and tough when fresh, is generally esteemed, when dried and salted, to be the best of stockfish. It belongs to northern regions, and is very abundant in the Shetland Isles, on the coasts of Norway and of Iceland. Another species is found on the coasts of New England, while an ally (*Brosmophycis marginatus*) is common on the Pacific shores.

TO'RSO (Ital.), strictly, signifies a trunk, e. g., the trunk of a tree, but is specially applied to an ancient statue of which only the body remains. Of such imperfect relics of classic art, the most famous is the *Torso of Hercules*, a masterpiece of manly beauty discovered in the Campo del Fiore at the beginning of the 16th c., and placed, by order of Pope Julius II., in the Vatican.

TORSTENSOHN, LEONARD, Count of Ortala, the most active, enterprising, and successful of the Swedish generals who were engaged in the Thirty Years' War (q. v.), was born at Torstena, 17th August 1603, became one of the royal pages in 1618, and attended Gustavus Adolphus in most of his earlier campaigns. When Gustavus entered Germany in 1630, T. was captain of the body-guard; and the brilliant services he rendered at Breitenfeld, the Lech, and on other occasions, were rewarded with rapid promotion. Taken prisoner at the combat of Nuremberg (24th August 1632), he was subjected to rigorous treatment, which so ruined his health, that on his exchange six months after, he returned to his post in the Swedish army a confirmed invalid; yet a vigorous mind and energetic character so overmastered bodily infirmity, that though reduced to the necessity of being always conveyed in a litter, he proved himself a most able officer under Bernhard of Weimar and Baner, the successors of Gustavus. In 1641, on the death of his former chief, the able and chivalrous Baner, he was appointed to the command in chief of the Swedes in Germany. His military career was marked by a brilliancy of conception, fertility of resource, resolute daring, and above all, by an extraordinary rapidity of execution, which broadly distinguished it from those of his contemporaries, and set at naught all the precautionary and defensive measures of his opponents. Having recruited and equipped his army, he invaded Silesia, routed the Austrians at Glogau and Schweidnitz, reduced most of Moravia, and being pressed back into Saxony by the Archduke Leopold and Piccolomini, gallantly turned upon the multitude of his pursuers (2d November 1642), and on the field of Breitenfeld, where Tilly's reputation for invincibility was cast down in the dust by Gustavus, inflicted a bloody defeat on the same adversaries; he then resumed the execution of his plans of invasion, and laid Moravia and Austria under contribution. Ferdinand III., despairing of protecting his territories from T., negotiated with Christian IV. of Denmark to make a diversion by invading Sweden; but T., with characteristic promptitude, left Moravia in September 1643, traversed Saxony and the Upper Palatinate, burst into Holstein, and in less than six weeks subjugated the Danish mainland. The Austrians under Gallas followed in pursuit of him, to aid their allies, but arrived too late; and in attempting to coop him up in Holstein, were routed, and driven into Saxony; and again totally defeated (23d November 1644) at Jüterbogk, in attempting to bar his return into Bohemia. Gallas was now deposed; but a combination of talented generals, as Montecuculi, Goertz, and others, was found to be equally ineffective against the resistless Swede, who, by a great victory at Yankovitz (16th March 1645), secured the navigation of the Danube, and the possession of the hereditary countries north of it. The emperor, empress, and principal nobility now deserted the capital; the Saxons again joined the Swedes; and the Danes, routed at sea as well as on land, besought peace, which was granted (13th August 1645). At this time, when a few more of T.'s weighty blows would have completely unseated the Hapsburg family, his gradually increasing ailments compelled him to resign the command to one very much his inferior, and retire to Sweden, where he experienced a most distinguished reception from Queen Christina, was created a count, and appointed to various high

offices successively. He died at Stockholm, 7th April 1651.

TORT (Lat. *tortus*), in the law of England, includes all those wrongs for which a remedy by compensation or damages is given in a court of law, and which wrongs arise irrespective of any contract. Such are assaults, imprisonments, taking one's goods without title, injury to one's body or character. The general rule of law was, that the right of action for a tort died with the person who committed it; but this defect has been cured by statute to a certain extent. If the wrong was done within six months preceding the wrongdoer's death, an action may be brought against his executors within six months after they have assumed office. So if the injured party lived, he could always bring an action of damages; but if he died, his executors or relatives could not do so, until Lord Campbell's Act enabled the wife, husband, parent, or child of such deceased injured party to sue for damages; and in such case the jury may apportion the damages between the widow and children who sue. The right to bring an action for a tort is limited to two, four, or six years respectively, according to the nature of the wrong.—In Scotland, there is no time limited for bringing the action.

TORTEAU. See ROUNDLE.

TO'RTOISE (*Testudo*), a genus of Chelonian reptiles, which once included the whole order, but is now much restricted. The popular name T. is never given to the marine Chelonians, which are called Turtles (q. v.), and although it is sometimes given—generally with a prefix, as Marsh T., River T., Fresh-water T.—to the kinds which inhabit fresh water (see EMYS and TERRAPIN), yet when used by itself, it is commonly the designation of what are distinctively called Land Tortoises, which belong to the genus *Testudo* as now restricted, and the genera most nearly allied to it. In *Testudo*, the carapace is of a single piece, bulged, and soldered by the greater portion of its lateral edges to the *plastron* (see CHELONIA); the legs are very short; the toes are very short, and united to the

Land and Water Tortoises:
1, Common Land Tortoise (*Testuda Græca*); 2, Lettered Tortoise (*Emys scripta*).

nails, which are thick and conical, five on the fore-feet, and four on the hind-feet. The species are numerous and widely distributed, inhabitants of the warmer temperate and of tropical countries. They all feed on vegetable food. None of them are found in Britain, but several in the countries around the Mediterranean. The most common of these is the GREEK T. (*T. Græca*), which attains a length of 12 inches, and has a broad and equally bulged carapace; the scales of which are granulated in the centre, striated on the margins, and spotted or marbled with black and yellow. This is the species of an individual of which a most interesting account is given by White in his *Natural History of Selborne*. It lives to a very great age, 100 years or more, as probably do all the other species, and spends the winter in a dormant state, as do all those which are not inhabitants of tropical climates; selecting for itself a place of hybernation when cold weather begins to come on, or preparing it by scooping a hole in the earth. During the heat of summer, it feeds voraciously; but in colder weather, both before and after its hybernation, it eats little. The love-season, which is in the beginning of summer, is one of great activity, and tortoises express their amorous desires by striking their shells against those of their mates. The Greek T. is used for food in some parts of the south of Europe. The flesh of all species of T. appears to be good for food, and the eggs of all are regarded as delicacies. A very large species is the Indian T. (*T. Indica*), if several species are not confounded under that name. It has been found on the coast of Coromandel, four feet and a half in length, its bulge being about fourteen inches. It is particularly abundant in the Galapago Islands, and has even been supposed by Darwin to be originally a native of them, and to have been diffused from them by the bucaneers over other tropical regions. It is known that the bucaneers often carried away tortoises alive from the Galapagos, but this fact does not seem probably to account for the abundance of the species in other places. The Galapago T. is often 200 lbs. in weight. Its flesh is of excellent quality, as are also its eggs. It forms tracks from the arid districts near the shore to the high districts of the islands, where there are springs, for the purpose of drinking; and these tracks, which are broad and well beaten, are traversed apparently at irregular intervals, the animal swallowing a very large quantity of water at a time, so that its bladder is greatly distended, and the water contained in the bladder is at first almost pure, and is gradually absorbed. The numbers of tortoises in some tropical and subtropical countries are very great. Professor E. Forbes speaks with admiration of the numbers of *T. Græca* and *T. marginata* straying about the plains of Lycia, and browsing on the fresh herbage in spring. Darwin describes the tortoises of the Galapagos as very numerous; and Leguat, in his account of the French Protestant expedition to the island of Rodriguez, in the beginning of last century, declares that the tortoises often came out together in such numbers to feed, that a man might have walked for a considerable distance on their backs as on a pavement.

Tortoises exhibit very little intelligence; they are, however, capable of recognising the hand that feeds them.

TORTOISE-SHELL, the large scales of the carapace, or shield, of a species of sea-turtle, the *Chelonia imbricata* and *Testudo imbricata* of several authors—*Caretta imbricata* of Dr Gray. It is found in the Indian Ocean, Amboyna, New Guinea, Seychelles, Havana, and the Red Sea. Tortoise-shell is so called because formerly the order of animals to which it belongs was little known, and all were confounded under the general name of Tortoises. A remarkable peculiarity in this species is the arrangement of the thirteen plates forming the carapace, which, instead of being joined together by their edges, so as to

make apparently one piece, are thinned off at their edges, and overlap each other like the tiles of a roof. They vary in size according to the part of the shield they occupy. The larger are sometimes from a foot to 18 inches long, by 6 inches broad; the thickness rarely exceeds the eighth of an inch. The beautiful mottled colour and semi-transparent characters of this material are well known. A remarkable quality is possessed by tortoise-shell, which very greatly increases its usefulness for the ornamental purposes to which it is generally applied—that is, its property of being easily softened by a heat equal to boiling water, and of retaining any form when cold which has been given to it when heated. Pieces can also be welded together by the pressure of hot irons properly applied. In Britain, the chief use of tortoise-shell is making combs for the hair; but it is also used for inlaying small pieces of ornamental furniture and various other fancy objects. In India, China, and Japan, its use is well understood, and some very beautiful articles are made of it, exhibiting great skill and taste. Great Britain alone consumes about 15½ tons, of the value of about £24,000.

TORTO'LA. See VIRGIN ISLANDS.

TORTO'NA (anc. *Antilia*, or *Dertona*), a town of Northern Italy, in the province of same name, and situated on the right bank of the Scrivia (a small river which flows north to join the Po), and 13 miles east of Alessandria, with which it is connected by railway. Pop. about 15,000. The principal buildings are the *Duomo* and church of San Francesco. T. has manufactures of silk, leather, hats, &c. It was a notable place in the middle ages—the old walls, and the ruins of a castle in which Frederick Barbarossa lived, being a relic of those turbulent times.

TORTO'SA (anc. *Dertosa*), an old and fortified town of Spain, province of Tarragona, picturesquely situated on a sloping eminence overlooking the Ebro, from the mouth of which it is distant about 22 miles. The streets are narrow, and the place has altogether a dull look. Some inconsiderable manufactures are carried on, and the sturgeon and lamprey fisheries afford employment to considerable numbers. Pop. upwards of 20,000.

TORTU'GAS (Sp. Turtles), a group of ten islets or keys, also called the Dry Tortugas, belonging to the United States, at the entrance of the Gulf of Mexico, 120 miles west-south-west of Cape Sable, the southern point of Florida. They are low coral islets, partly covered with mangrove bushes. There has been a light-house erected on Bush Key; and refractory soldiers, and prisoners connected with the War of Secession, have been employed in erecting a fort, called Fort Jefferson.

TORTURE. Examination by torture, otherwise called 'The Question,' has been largely used in many countries as a judicial instrument for extracting evidence from unwilling witnesses, or confessions from accused persons. In ancient Athens, slaves were always examined by torture, and their evidence seems on this account to have been deemed more valuable than that of freemen. Any one might offer his own slave, or demand that of his opponent, to be examined by torture; and it was supposed to constitute a strong presumption against any one that he refused to give up his slave for that purpose. No free Athenian could be examined by torture, but torture seems occasionally to have been used in executing criminals. Under the Roman Republic, only slaves could be tortured, and as a general rule, they could not be tortured to establish their masters' guilt. Under the Empire, torture, besides being much used in examining slaves, was occasionally inflicted even on freemen, to extract evidence of the crime of *læsa majestas.* Cicero and other enlightened Romans wholly condemned its use. Until the 13th c., torture seems to have been unknown to the canon law; about that period, the Roman treason-law began to be adapted to heresy as *crimen læsæ majestatis Divinæ.* A decree of Pope Innocent IV., in 1282, calling on civil magistrates to put persons accused of heresy to the torture, to elicit confessions against themselves and others, was probably the earliest instance of ecclesiastical sanction being adhibited to this mode of examination. At a later period, however, torture came to be largely employed by the inquisitors.

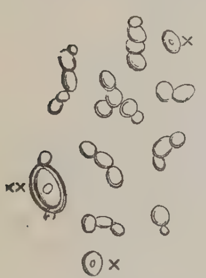
From the civil law, torture became a part of the legal system of most European countries. It was adopted early, and to a large extent, by the Italian municipalities. In Germany, elaborate apparatus for its infliction existed, not merely in the dungeons of the feudal castles, but in the vaults beneath the town-halls of Nürnberg and Ratisbon, where the various implements used are yet to be seen. It continued to be practised in the prisons of Germany when they were visited by Howard in 1770. In France, it was part of the judicial system till 1789, and in Scotland it was still in frequent use after the Restoration, and was only abolished by 7 Anne, c. 21, s. 5.

The use of torture seems always to have been repugnant to the genius of the law of England; though occasionally used by an exercise of prerogative, it may be doubted whether it was ever recognised as lawful in the ordinary course of the administration of justice. The first instance we have of its use is in 1310, in aid of the ecclesiastical law, during the struggle between Pope Clement V. and the Templars. Edward II., when applied to to sanction the infliction of torture by the inquisitors in the case of certain Templars accused of heresy and apostasy, at first refused; but on a remonstrance by Clement, he referred the matter to the Council; and on the recommendation of the Council, the inquisitors were authorised to put the accused to the torture, but without mutilation or serious injury to the person, or effusion of blood. During the Tudor period, the Council assumed the power of directing torture-warrants to the lieutenant of the Tower, and other officers, against state prisoners, and occasionally also against persons accused of other serious crimes; and similar warrants were at times issued under the sign-manual. Under James I. and Charles I., torture was less resorted to, and only in state trials. In 1628, in the case of Felton, the assassin of the Duke of Buckingham, the judges declared the examination of the accused by torture, for the purpose of discovering his accomplices, to be illegal. Torture was inflicted for the last time in England in May 1640. It is now disused in all countries of Europe, and is universally acknowledged to have been a most unsatisfactory mode of getting at the truth; often leading the innocent, from weakness of body, to plead guilty to crimes which he had not committed.

The instruments of judicial torture have been various. The most celebrated is the Rack, an oblong horizontal frame, on which the accused was stretched, while cords, attached to his legs and arms, were gradually strained by a lever or windlass, an operation which, when carried to extreme severity, dislocated the joints of the wrists and ankles. It is as old as the 2d c. in the south of Europe, but is said to have been unknown in England till introduced into the Tower by the Duke of Exeter, Constable of the Tower, whence it acquired the name of the 'Duke of Exeter's Daughter.' In Germany, the rack was sometimes furnished with a roller, armed with spikes, rounded off, over which the sufferer was

drawn backwards and forwards. A vertical rack was also in use in that country. The person subjected to it was raised to the roof by a rope attached to his arms, which were bound behind his back; and two heavy stones having been attached to his feet. the rope was loosened so as to let him fall with a jerk to within a few inches of the ground. Among the lesser tortures may be mentioned the Thumbikins, Boots, Pincers, and Manacles; and in England, an instrument called the Scavenger's (properly Skeffington's) Daughter, the invention of Sir W. Skeffington, lieutenant of the Tower in the reign of Henry VIII.

TO'RULA CEREVI'SIÆ, or the YEAST-PLANT, is one of those fungi which are connected with the process of fermentation. The general history of this fungus will be noticed in the article YEAST, and we shall here only refer to the medicinal bearing of the subject. This plant, which is also known under the names of *Saccharomyces*, *Mycoderma cerevisiæ*, and *Cryptococcus fermentum*, may be readily observed by examining a little yeast under the microscope, when it will be seen in the form of round or oval corpuscles (cells), varying in diameter from the 800th to the 400th of a line, and many having smaller corpuscles in their interior. They grow by protrusion of gemmules, and germinate sometimes on one, and sometimes on several spots of the primitive fungus cells. These shoots throwing off new gemmules, the yeast-plant gradually forms single or branching rows of oblong cells, connected together like beads. This peculiar arrangement of the cells, and the fact that they are not acted on by acetic acid, is characteristic of the plant.



The Yeast-plant, taken from a fluid ejected in large quantities from the stomach of a man suffering from stricture of the pylorus. Magnified 200 diameters.

In those cells marked ×, a young cell is seen growing in the interior; while in the large cell marked ××, there is a simultaneous internal production and external gemmation of cells.

This fungus exists in the saccharine urine of *diabetes mellitus*, after it has been discharged for 24 hours or longer, and its appearance in urine within a day or two is sufficient to lead to the suspicion of the presence of sugar. It likewise is of not unfrequent occurrence in vomited matters and in fæcal evacuations; and wherever it is found, it is indicative that the fluid is in a state of saccharine fermentation.

As fungi more or less closely resembling the yeast-plant often occur in non-saccharine urine that has stood for some days, the assumed presence of the T. C. must not be taken as a proof of the presence of sugar, although it affords a strong hint for testing for that substance.

TO'RUS, the convex member of the base of classic columns. See COLUMN.

TOTEM (a god). See SUPPLEMENT in Vol. X.

TOSHACH (Celtic, captain), the name which was given among Celtic nations to the military leader of a clan or tribe, whose functions were in early times always separated from those of the supreme judicial officer. When the office of toshach, originally elective, became hereditary, according to the principle of divided authority characteristic of Celtic communities, it remained permanently in the eldest cadet of the clan. See TANISTRY.

TOTIPA'LMÆ, Cuvier's name for a group of birds, of the order *Palmipedes*, having the hind-toe connected with the other toes by a web. Pelicans, cormorants, frigate-birds, gannets, and darters belong to this group. All the T. are marine; they feed on fishes, molluscs, and other marine animals, and are excellent swimmers and divers. Many of them have long wings, and are birds of powerful flight.

TOTNES, or TOTNESS, a municipal, and formerly a parliamentary, borough and market-town of Devonshire, situated on the slope of a steep hill, on the right bank of the river Dart, about 10 miles from its mouth. It is a place of great antiquity, has an interesting church of the 15th c., and some curious antique houses; the ruined keep of the ancient castle, on the summit of the hill, is said to have been built by Joel de Totneis, a Norman baron, on whom the manor was bestowed at the Conquest, and who founded here also a Cluniac priory. The river Dart is navigable for vessels of 200 tons up to the town, which is a place of some little shipping trade. The borough, which comprised also the suburb of Bridgetown, was disfranchised for corrupt practices by the Reform Bill of 1867. Steamers ply during the summer months between T. and Dartmouth. It is a station on the South Devon Railway. Pop. (1881) 4089.

TOU'CAN (*Ramphastos*), a Linnæan genus of birds, now forming the family *Ramphastidæ*, which belongs to the order *Scansores*, and contains nearly forty known species, all natives of tropical America, and remarkable for the magnitude of the bill. They are divided into two groups, the true Toucans (*Ramphastos*), and the Aracaris (q. v.) (*Pteroglossus*), of which the latter contains the greater number of species: the former has the largest bill, and the tail is shorter. There is a difference also in the prevalent colours, the aracaris generally exhibiting much

Toucan (*Ramphastos Toco*).

green and yellow, whilst the true toucans have the ground colour of the plumage usually black; the throat, breast, and rump often gaily adorned with white, yellow, and red. The colours, however, are not in general finely blended, but appear in strong contrast. The legs of toucans are short; the feet have two toes before and two behind. The form of the body is short and thick; the tail is rounded or

even, varying in length in the different species from half the length to almost the whole length of the body, and is capable of being turned up over the body in a remarkable manner, which it always is when the bird is at roost. The neck is short and thick; the enormous bill is at the base of the full width and depth of the head, and is in some species more than half the length of the body. It is arched towards the tip, irregularly toothed along the margins of the mandibles, and extremely cellular and light, yet strong in structure. The tongue is very long, narrow, and singularly feathered on each side, the processes which give it this feathered appearance probably adding much to its sensibility as an organ of taste. When a T. takes food between the points of the mandibles, the tongue is immediately applied to it, as if to test or enjoy it, and afterwards it is tossed into the throat by a sudden throwing back of the head. Toucans may almost be described as omnivorous; they eat fruits with avidity, but they also seize and devour small birds. Their powerful bill enables them to kill a small bird by a single squeeze. They make a curious clattering noise with their great mandibles, and also emit at times a harsh cry. They live chiefly in the depths of the South American forests, in small flocks. They are easily tamed, and bear cold climates well. In captivity, they readily eat rice, bread, potatoes, eggs, and many other kinds of food. They are remarkable amongst birds for regurgitation of food, in order to a kind of mastication in the great bill, analogous to rumination in quadrupeds. The colours of the bill are, in most of the species, very brilliant during life, but disappear from stuffed specimens in museums. The largest species, as *Ramphastos Toco*, are about 27 inches in length, the bill in this species measuring $7\frac{1}{2}$ inches, and the tail 10 inches.

TOUCH is the sense through which we take cognizance of the palpable properties of bodies. It is used in two senses. In its extended acceptation, it implies, says Dr Carpenter, 'our consciousness of *all* those sensory impressions which are neither olfactive, visual, auditory, nor gustative; and it is therefore designated as the *general sense*, in contradistinction to those which are considered as *special senses*. In its limited application, on the other hand, it is used to designate that modification of the general sensibility which is restricted to the tegumentary surface, or to some special portion of it, and which serves to excite definite ideas in our minds respecting the form, size, number, configuration, weight, temperature, hardness, softness, &c. of objects brought within its cognizance.'—Article 'Touch,' in *Cyclopædia of Anatomy and Physiology*, vol. iv. p. 1163. In the article SENSIBILITY, we have briefly noticed touch in its general sense; and we shall here confine ourselves to the investigation of the sense of touch in its limited application, as exercised by the organs specially adapted for the reception of tactile impressions.

The special organs of touch are the papillæ, which are figured and very briefly noticed in the article SKIN. These papillæ are more elevated and numerous on the palmar surface of the ends of the fingers than on any other part of the skin (although they are still larger on the tongue). They have an average length in man of $\frac{1}{100}$th of an inch. Their surface, after the removal of the epidermis, appears, from the investigations of Todd and Bowman, to be composed of the basement membrane of the cutis itself; and their interior is composed of fibrous tissue, vessels, and nerves, as is seen in the figures of the lingual papillæ given in the article TASTE, SENSE OF. In each papilla is a small arterial twig, which, entering at the base, subdivides into capillary essels, which form loops, whose convexity lies in the papillary summit. The vascularity of the papillæ is so great, that their presence and relative size may be determined simply by the depth of the colour imparted to the skin by a good injection of its vessels. Hence, as a general rule, the vascularity of the integument is proportioned to its perfection as an organ of touch. With regard to the mode in which the nerves terminate, there is still considerable doubt. According to Todd and Bowman, it is often impossible to detect any nerves at all within the papillæ, when such were plainly visible at their base; and they incline to the belief, that the nervous tubules either entirely, or in a great measure, lose the white substance when within the papillæ.

In the lower animals, as in man, the papillæ are especially developed in those parts of the outer surface which are especially endowed with tactile sensibility. For the following illustrations of this statement, drawn from comparative anatomy, we are indebted to Dr Carpenter: 'In the quadrumana generally, both the hands and feet are thickly set with papillæ; and in those which have a prehensile tail, the surface of this organ possesses them in abundance. In the carnivorous and herbivorous mammalia, whose extremities are furnished with claws, or encased in hoofs, we find the lips and the parts surrounding the nostrils to be the chief seat of tactile sensibility, and to be copiously furnished with papillæ; this is especially the case with those which have the lips or nostrils prolonged into a snout or proboscis—as in the pig, the rhinoceros, the tapir, and the elephant. In the mole, too, the papillary structure is remarkably developed at the extremity of the snout. The only part of the skin of birds on which tactile papillæ have been discovered is on the under surface of the toes, and on the web of the palmipedes, where they obviously receive impressions which guide the prehensile and other movements of the feet. In many lizards, a papillary structure is found on the under surface of the toes; and in the chameleon, it exists also on the integument of its prehensile tail. . . . . In serpents and chelonians (tortoises), no papillary apparatus has as yet been detected; and in fishes and invertebrata, its presence has not been ascertained, although it would appear that certain parts, especially the tentacles around the mouth, are endowed with a high degree of tactile sensibility.' —*Op. cit.*, p. 1166. It is probable that in all animals which have a soft fleshy tongue furnished with papillæ, this organ is an instrument of tactile sensibility as well as the organ of taste. Besides the papillary apparatus, certain animals have special organs of touch, constructed on a totally different plan, and 'consisting of a rod or filament, which is in itself insensible, but which is connected at its base with nervous fibres in such a manner that any motion or vibration communicated to it must be transmitted to them.' The so-called 'whiskers' of the cats and certain rodents, as the hare and rabbit, belong to this class; and it has been proved, experimentally, that if they be cut off, the animal loses, to a great extent, its power of guiding its movements in the dark.

Amongst the conditions necessary for the exercise of the sense of touch are (1) a normal condition of the papillary apparatus and of the nerves supplying it; (2) a due supply of blood to the tactile organs; and (3), as has been noticed in the article TASTE, a temperature not too far removed from the natural heat of the body. It has been shewn by Professor Weber, that if the fingers or the lips be immersed for half a minute or a minute in water heated to 125°, or cooled to 32°, the power of distinguishing between a hot or cold fluid or solid body is for the time completely lost, a feeling of pain alone being experienced. The result was the same on applying

cold to the trunk of a nerve, the ulnar nerve at the elbow, where it lies just beneath the skin, being selected for the experiment. The fingers supplied by this nerve soon lost the power of distinguishing between heat and cold, and could only imperfectly perceive the contact and pressure of bodies.

The above-named physiologist has made a large number of experiments on the general subject of Touch. His investigations regarding the tactile discrimination in different parts of the skin have been noticed in the article SENSIBILITY. Professor Valentin, whose results, on the whole, correspond very closely with those of Weber, found, however, a considerable extent of individual variation, some persons being able to distinguish the separate compass-points at half or even one-third of the distances required by others.

There is no sense which is so capable of improvement as that of touch. Of this power of improving the delicacy of touch, says Dr Carpenter, 'we have examples in the case of certain artisans, whose employments require them to cultivate their tactile discrimination; thus, the female silk-throwsters of Bengal are said to be able to distinguish by the touch alone *twenty* different degrees of fineness in the unwound cocoons, which are sorted accordingly; and the Indian muslin-weaver contrives by the delicacy of his touch to make the finest cambric in a loom of such simple construction that European fingers could at best propose to make a piece of canvas at it.' The highest degree of tactile sensibility is met with in blind persons—a circumstance which is to be attributed for the most part to the concentration of the attention and of the powers of recollection and comparison which are brought to bear upon the mind; and probably to some extent to an increased development of the tactile organs themselves, resulting, as the above-named physiologist suggests, 'from that augmented nutrition which would be the natural consequence of the frequent use of them, and of the increased flow of blood that seems to take place towards any part on which the attention is constantly fixed.'—For much interesting information on this subject, the reader is referred to Dr Kitto's *Lost Senses*, in which cases, apparently quite authentic, are given of blind persons being able to distinguish colours by the touch.

TOUCH-HOLE, or **VENT**. See GUN.

TOUCH-PAPER. See NITRE.

TOUCH-STONE, a hard black stone, occasionally used in assaying. The best kind is a peculiar bituminous quartz obtained from Lydia, in Asia Minor; but black basalt may be employed. The process is as follows: A series of 'needles' or small bars are formed, the first consisting of pure gold; the second, of 23 of gold and 1 of copper; the third, of 22 of gold and 2 of copper, and so on. The assayer selects one of these alloys, or 'needles,' which, from its colour, he judges to approach nearest in composition to the alloy which he is about to assay. This he rubs on the stone, and the streak which it leaves is red in proportion to the copper that is present. The streak formed by the alloy to be assayed is then compared with that formed by the various 'needles,' and corresponding streaks indicate corresponding amounts of copper. Hence, an approximate estimate of the amount of copper in an alloy can be made.—See Miller's *Inorganic Chemistry*, 2d ed., p. 739, *note*.

TOUCH-WOOD is the wood of willows and some other trees softened by decay. It is used as tinder for obtaining fire, from the readiness with which a spark ignites it.

TOUL, a fortified town of Lorraine, dep. of Meurthe, on the Moselle, and a station on the Paris and Strasburg Railway, 12 miles west of Nancy. It has an old cathedral, which took more than five centuries to finish (965—1496), and which was reckoned one of the most splendid in France. Cotton, woollen, lace, and fayence manufactures are carried on. Pop. 7687.

TOU'LA, or **TULA**, one of the governments of Great Russia, bounded on the N. by the government of Moscow. Area, 11,772 sq. m.; pop. 1,152,470. The surface is for the most part level; the climate is temperate; the soil, fertile. The Oka is the only river which is navigable throughout the government, and the other streams are tributaries either of the Oka or the Don. The surface is in general dry, there being no lakes or marsh-lands, and forests are rare. The inhabitants are occupied chiefly in agriculture, cattle-breeding, the manufacture of pottery, fishing, and the working of iron mines.

TOULA, or **TULA**, an important manufacturing town of Great Russia, capital of the government of the same name, on the Upa, an affluent of the Oka, 110 miles south of Moscow. Its 28 churches, its arsenal, theatre, industrial museum, cathedral, and the ancient Kreml are the principal buildings. T. is an ancient town, and has suffered severely from Tartar invasion, and during the wars of the commencement of the 17th century. Iron-works founded here under Czar Alexis Michailovitch have acquired a well-merited reputation. The Russian army is largely supplied with muskets and small-arms from the works of this town. Cutlery, locks, tea-urns, and bells are made in great perfection; and bristles are prepared in large quantities both for home consumption and export. Pop. 56,496.

TOULON, a great seaport and naval arsenal of France, in the dep. of Var, stands on the shore of the Mediterranean, 37 miles south-east of Marseille, with which it is connected by railway. It stands at the head of a deeply penetrating inlet or gulf, rises in the form of an amphitheatre towards the north, where its ramparts extend to the foot of a chain of lofty elevations, in part clothed with beautiful forests. The port is divided into two parts, the old and the new; the former, on the east, appropriated to merchant-vessels, and bordered by a quay; the latter, on the west, surrounded by the dockyard, slips, arsenal, storehouses, cannon-foundry, &c. Numerous forts defend the town on the land-side; and the mouth of the harbour, and the hills commanding it, are studded with forts and redoubts; while moles, hollow and bomb-proof, and formed externally into batteries, level with the water's edge, separate the roadstead from the old and new ports. Belonging to the arsenal, which is perhaps the finest in France, the chief objects of attraction are the sail-yard, the armoury, the museum, the magazine, and the basin for the repair of ships. The fortifications of the town have been greatly extended since the conquest of Algeria, T. having become the chief port of communication with Africa. The population has also greatly increased, and two new suburbs have been constructed. The town is surrounded by a double rampart, and by a wide and deep fosse. The streets are straight and wide; and, on the whole, the town is both agreeable and healthy. This town is the Plymouth of France; and its industry consists, for the most part, of those manufactures to which its position as a great naval arsenal gives rise. Pop. (1866) 77,126; (1881) 70,103.

T. was destroyed by the Saracens in 889, and again by the Saracens about the close of the 12th

century. It is only at the end of the 16th c. that T. comes to be important as a naval and military stronghold. It was taken by the English and Spaniards in 1793; but the allies were obliged to evacuate the town in December of the same year, after being fiercely attacked by the Republicans, whose guns were commanded by Napoleon—then a simple officer of artillery—who here evinced for the first time his genius and self-reliance.

TOULOUSE (anc. *Tolosa*), an important city in the south of France, capital of the dep. of the Haute-Garonne, is situated in a broad and pleasant plain, on the right bank of the river Garonne, 160 miles by railway south-east of Bordeaux. Pop. 126,936. The *Canal du Midi* sweeps round its eastern and northern sides. The Garonne is here crossed by a beautiful bridge upwards of 810 feet in length, and 72 broad, which connects T. with the suburb of St Cyprien. The city, with the exception of the southern faubourg, is not particularly handsome (though the broad quays have rather an imposing appearance), and there are few fine public buildings. One may note, however, the cathedral, containing the tombs of the counts of Toulouse; the *Capitole*, or town-hall; the church of St Sernin (1090 A.D.); the Musée, with its interesting collection of antiquities, forming an almost uninterrupted chain in the history of art, from the Gallo-Roman to the Renaissance period. T. is the seat of an archbishop, has a university academy, an academy of 'floral games' (*Société des Jeux Floraux*), pretending to derive its origin from the contests of the ancient troubadours, academies of arts, sciences, antiquities, &c., schools of law, and medicine, and artillery, a national college, an observatory, a museum, botanic garden, and a public library of 50,000 volumes. T. manufactures woollens, silks, leather, cannon, steam-engines, tobacco, brandy, &c., and carries on a great trade with Spain. Its duck-liver and truffle pies are celebrated throughout the south of France.

History.—Tolosa was, in Cæsar's time, a city within the limits of the Roman *Provincia*, and had been originally the capital of the Volcæ Tectosages, a Gallic tribe noted for its wealth and consequence. Under the empire its importance continued. Ausonius describes it as surrounded by a brick wall of great circuit, and so populous that it had founded four colonies. In 412 A. D., the Visigoths made it the capital of their kingdom; and after the time of Charlemagne, it was under the sway of counts, who made themselves independent about 920, but in 1271 the 'county of T.' was reunited to the crown of France by Philippe *le Hardi*. Its literary celebrity reaches as far back as the Roman Empire. Ausonius speaks of the *toga docta* of 'Palladian' Tolosa, and the favourite deities of the city were Jupiter, Minerva, and Apollo. At a little village close by, which still bears the name of *Viel Toulouse*, a multitude of cinerary urns, statuettes, Phœnician, Celtiberian, Gallic, Greek, and Roman medals, fragments of buildings, and an entire paved street have been discovered. Early in the middle ages, under the Counts of T. it became a seat of Provençal poetry, and was the centre of the papal crusade against the Albigenses, conducted by Simon de Montfort. The Parliament of T. had also a great reputation, but unhappily it is likely to be best remembered by one of its most iniquitous decisions, that delivered in the case of the Calas (q. v.) family.

TOURAINE, one of the former provinces of France, of which the capital was Tours (q. v.), and which was bounded on the N. by the province of Orleannais, on the E. by Berri, on the S. by Poitou, and on the W. by Anjou. It was about 60 miles in length, and nearly the same number of miles in breadth, and it appears on the map now as the department of Indre-et-Loire.

TOURCOING, a frontier town of France, dep. of Nord, $7\frac{1}{2}$ miles north-east of Lille, is built on an eminence in the midst of a fertile territory. It has a great reputation for its manufacture of linen-cloths, and also carries on sugar-refining, distilling, and manufactures of soap, colours, &c. Pop. about 40,000.

TOU'RMALINE, a mineral ranked amongst Gems (q. v.), and occurring in primitive rocks in many parts of the world. Its chemical composition is very complex and somewhat various, but the chief constituents are always silica and alumina in about equal proportions, and forming about three-fourths of the whole; the remainder consisting of boracic acid, fluorine, phosphoric acid, peroxide of iron, peroxide of manganese, protoxide of iron, magnesia, lime, soda, potash, and lithia, which are not, however, all present in any specimen. T. is harder than quartz, but not so hard as topaz or emerald. Its specific gravity is a little more than 3. It occurs in crystals, or massive and disseminated, although always crystalline. Its lustre is vitreous. Some varieties are transparent, some translucent, some opaque. Some are colourless, some green, brown, red, blue, and black. Red T. is known as *Rubellite;* Blue T., as *Indicollite;* and Black T., as *Schorl*. This last is the most common kind. T. crystallises in prisms, with 3, 4, or 9 sides, variously acuminated. The sides of the prisms are striated. The finest tourmalines are much valued by jewellers, but are comparatively rare. They mostly come from Ceylon, Siberia, and Brazil. Magnificent red and green tourmalines are found at Paris and Hebron, Maine, and other varieties in the U. S. and Canada.

TOU'RNAMENT (Fr. *tournoi*, from *tournoyer*, to turn round), a military sport of the middle ages, in which combatants engaged one another with the object of exhibiting their courage, prowess, and skill in the use of arms. The invention of the tournament has been ascribed to Geoffroy de Prenilly, ancestor of the Counts of Anjou, who lived in the 10th c.: France was its earliest *locale*, whence it spread first to Germany and England, and afterwards to the south of Europe. A tournament was usually held on the invitation of some prince, who sent a king-of-arms or herald through his own dominions and to foreign courts signifying his intention of holding a tournament and a clashing of swords in presence of ladies and damsels. The intending combatants hung up their armorial shields on the trees, tents, and pavilions round the arena for inspection, to shew that they were worthy candidates for the honour of contending in the lists in respect of noble birth, military prowess, and unspotted character. The combat took place on horseback, or at least was always begun on horseback, though the combatants who had been dismounted frequently continued it on foot. The usual arms were blunted lances or swords; but the ordinary arms of warfare, called arms *à l'outrance*, were sometimes used by cavaliers who were ambitious of special distinction. Tournaments were the subject of minute regulations, which in some degree diminished their danger. The prize was bestowed by the lady of the tournament on the knight to whom it had been adjudged, he reverently approaching her, and saluting her and her two attendants. The period when tournaments were most in vogue comprised the 12th, 13th, and 14th centuries; and the place where the most celebrated English tournaments were held was the tiltyard

near St James's, Smithfield, London. The church at first discountenanced tournaments, some of its decrees prohibiting persons from engaging in them under pain of excommunication, and denying Christian burial to a combatant who lost his life in one. The church seems, however, to have looked with more favour on these combats after the middle of the 13th century. During the 15th and 16th centuries, tournaments continued to be held, but the alteration in the social life and warfare of Europe had changed their character, and they are rather to be regarded as state pageants than as real combats. The death of Henry II. of France, in 1559, consequent on the loss of his eye at a tournament, led to their general abandonment, both in France and elsewhere, and there have been few attempts to revive them even as mere spectacles. A magnificent entertainment, consisting of a representation of the old tournament, was given at Eglinton Castle in 1839, under the auspices of the late Earl of Eglinton: Lady Seymour was the Queen of Beauty, and many of the visitors enacted the part of ancient knights.

According to Ducange, the difference between a tournament and a JOUST is, that the latter is a single combat, while in the former a troop of combatants encounter each other on either side. But this distinction has not been always observed.

TOURNAY (Flemish, *Doornik*), a fortified town of Belgium, province of Hainault, on both sides of the Scheldt, near the French frontier. It has a splendid cathedral with five towers (and pictures by Jordaens, Rubens, Gallait, &c.), several fine churches, particularly St Quentin and St Jacques, a gallery of art, an episcopal seminary, five hospitals, and a lunatic asylum. Although one of the oldest towns in Belgium, it has quite a modern appearance, with fine suburbs and beautiful broad streets. The chief manufactures are hosiery, linen, carpets, and porcelain; but there are few large workshops, most of the fabrics being executed by the people in their own houses. Pop. about 35,000. A little to the south-east lies the famous village of Fontenoy (q. v.).

T., the ancient *Tornacum* or *Turris Nerviorum* ('Fort of the Nervii'), was in the 5th and beginning of the 6th centuries the seat of the Merovingian kings, subsequently belonged to France, but at the Peace of Madrid was included in the Spanish Netherlands. Subsequently, it was oftener than once taken by France, but again restored by treaty. During the month of May 1794, it was the scene of several hotly-contested fights between the French and Austro-English armies, the most important of which was that of the 19th May, in which Pichegru beat the Duke of York.

TOURNEFORT, JOSEPH PITTON DE, one of the greatest botanists of the 17th c., born at Aix, in Provence, in 1656. He exhibited an ardent love of botany from his youth, and devoted his whole life to this science. After having explored the flora of his native district, he was sent, at the king's expense, to Spain, Portugal, England, and Holland, and afterwards to the East. He visited the Grecian Archipelago and Thrace, the shores of the Black Sea, and Asia Minor, and added a great number of species to the list of known plants. He lost his life in 1708, in consequence of a carriage running against him in Paris. He published several botanical works, and a *Voyage to the Levant.* His botanical system, which maintained its ground till the time of Linnæus, was of great use in promoting the progress of botany; but he rendered still greater service to his favourite science by grouping plants in genera. He was the first to do so. Previous botanists had merely described them individually, as species.

TOURNIQUET, an instrument for compressing the main artery of the thigh or arm, either for the purpose of preventing too great a loss of blood in amputation, or to check dangerous hæmorrhage from accidental wounds, or to stop the circulation through an aneurism.

The common tourniquet consists of three parts—viz., (1) a pad to compress the artery; (2) a strong band which is buckled round the limb; and (3) a bridge-like contrivance over which the band passes, with a screw whose action raises the bridge and consequently tightens the band. The best kind of

Common Tourniquet.

pad is a small firm roller about an inch thick; it must be placed lengthways over the main artery so as to compress it against the bone, and must be secured in its place by a turn of bandage, over which the band of the tourniquet must be applied. This band must first be tightly buckled, and the pressure must be then increased to the necessary extent (namely, till the beating of the artery beyond the instrument ceases to be perceptible) by the action of the screw, which should always be opposite the buckle of the band. As the instrument arrests the venous blood, it should never be applied tightly in cases of amputation, until the surgeon is ready to make his incision, as otherwise there would be an excessive loss of venous blood.

The credit of the invention of this most useful instrument is usually ascribed to the French surgeon Morel, who, in 1674, used a stick passed beneath a fillet, and turned round so as to twist it up to the requisite degree of tightness, as a means of preventing the undue loss of arterial blood in amputations of the limbs—a rough, but by no means ineffectual form of tourniquet, which may often be usefully extemporised in cases of emergency at the present time. Mr Young of Plymouth, in 1679, described a similar apparatus. A much improved screw tourniquet was invented by Petit early in the following century.

TOUROUKCHA'NSK, a small town of East Siberia, in the government of Yeneseisk, stands on the Yenesei, 4122 miles east of St Petersburg, and only 50 miles south of the arctic circle. Pop. 8556, who trade in furs.

TOURS, a city of France, capital of the dep. of Indre-et-Loire, and formerly capital of Touraine.

stands in the midst of a fertile but flat valley, 146 miles by railway south-west of Paris. Along its north side runs the Loire, and along its south side the Cher—these two rivers uniting about 25 miles south-west of the city, between which and their point of confluence only a very narrow strip of land separates them. The bridge over the Loire, which continues the great highway from Paris south to Bordeaux, is upwards of 1400 feet long, and south from it runs the chief street of the city, the Rue Impériale, a fine avenue, at the entrance to which are the town-hall and the museum. The cathedral is a stately Gothic edifice. Surrounding the choir—begun in 1170—there is beautiful old painted glass. The Tour de St Martin or d'Horloge, and the Tour de Charlemagne, are noteworthy as being the only remains of the cathedral founded by St Martin in the 4th century. The church was pillaged by the Huguenots, and utterly destroyed, with the exception of the two towers mentioned, at the Revolution. At a short distance west of T. are the remains of Plessis les Tours, in which Louis XI. established his residence, and in which he died in 1483. Manufactures of silk stuffs, carpets, painted glass, and pottery are carried on. Pop. about 55,000.

T., the ancient *Cæsarodunum*, dates from the time of the Gauls, and was visited by Cæsar and by Adrian. Here Clovis, having come to thank St Martin for the victory of Vouillé, received the crown of gold and the purple robe presented to him by the Emperor Anastasius. Henry IV. planted the first mulberry-trees known in France here, and here the first silk-factories were established. Under Richelieu, 40,000 hands were employed at T. in this branch of manufacture; but the industry of the town was ruined by the revocation of the Edict of Nantes.

TOURVILLE, Anne Hilarion de Cotentin, Count de, third son of César de Cotentin, seigneur de Tourville, was born at Tourville in 1642. Entering the French navy when about eighteen, it seems that his somewhat delicate and effeminate appearance caused him to be regarded as anything but a hopeful seaman. He became, however, almost immediately conspicuous for bravery and enterprise; and the first six years of his naval service, directed against the Turks and Algerians, established his reputation both in France and in the south of Europe. In 1667, he was received at Versailles with great distinction by Louis XIV. In 1669, he distinguished himself in the expedition sent by France to the relief of Candia, then besieged by the Turks; and again in 1671—1672, in the naval war waged by the combined fleets of France and England against the Dutch. In 1682, he was made lieutenant-general of the navy, and for the following two or three years he was engaged in suppressing the pirates of Algiers and Tripoli. In the war which broke out after the English revolution of 1688, between France on the one part, and England and Holland on the other, T. was put at the head of the French navy. In June 1690, he entered the English Channel at the head of a powerful fleet, and inflicted a disastrous and ignominious defeat on the united English and Dutch armament near Beachy Head. 'There has scarcely ever been so sad a day in London,' says Macaulay, 'as that on which the news of the battle of Beachy Head arrived.' T. ranged the Channel unopposed; and on 22d July his fleet cast anchor in Torbay (see Macaulay, *History of England*, vol. iii. p. 652—654, ed. 1855). In 1692, Louis XIV. having resolved to invade England on behalf of James II., an immense fleet was assembled at Brest under T. in order to protect the descent. On the 16th May of this year the French fleet was descried from the cliffs of Portland, and on the following morning the English and Dutch force stood out to give battle. From the morning of the 19th to the afternoon of the 24th, raged one of the greatest naval battles of modern times, that of Cape La Hogue. It ended in the complete defeat of the French, 16 of their men-of-war being utterly destroyed. In spite of this disaster T. was graciously received at Versailles: 'We have been beaten,' said Louis to him, 'but your honour and that of the nation are unsullied' (see *Memoirs of St Simon*). On 27th March 1693, T. was made a Marshal of France. Sailing from Brest harbour in the spring of this year, he attacked an English merchant fleet under inadequate convoy, and succeeded in inflicting a damage on English traders estimated at some millions sterling. Sir George Rooke, who commanded the convoy, had some difficulty in saving his own squadron from destruction. This was the last exploit of the great French admiral; his career ending with the peace of Ryswick in 1697. He died at Paris, 28th May 1701. It has been said of T. that he was competent to fill any place on board ship, from that of carpenter to that of admiral. It has also been said of him, that to the dauntless courage of a sailor he united the suavity and urbanity of an accomplished gentleman. But though a brave man, he was, during the earlier part of his career, a timid commander. Reckless of his life, he was often pusillanimously cautious where his professional reputation was at stake. Latterly, stung by the censures drawn on him by his natural disposition, he became bold even to rashness.

TOUS-LES-MOIS, a starch made in the West Indies, from the roots of a species of canna (see Indian Shot); it is used as a substitute for arrowroot.

TOUSSAINT, Anna Louisa Gertrude, one of the most popular living Dutch novelists, was born at Alkmaar, September 16, 1812, where her father, a highly esteemed lecturer on chemistry, died in 1859. After the revocation of the Edict of Nantes, her paternal ancestors fled from France, and took refuge, first at Hanau, and later in Friesland, where they ranked among the nobility, but were reduced in circumstances during the French usurpation. By the mother's side, she is also of a refugee family of the name of Rocquette, belonging to the higher class of merchants and manufacturers. Her first work, *Almagro*, published in 1837, was well received, and translated into German. Speedily followed *De Graaf van Devonshire*, an episode in the early life of Elizabeth Tudor; then *De Engelschen te Rome*, a historical novel of the times of Pope Sixtus V.; in 1840, the *Huis Lauernessé*, a story of the Reformation, which has gone through several editions, and been translated into German and English. Her popularity was increased by a series of novels in 10 volumes, 1845—1855, under the titles of *De Graaf van Leycester in Nederland* (The Earl of Leicester in the Netherlands), *De Vrouwen van het Leycestersche tijdperk* (The Women of the Times of Leicester) and *Gideon Florentz.* Her other works are numerous including *Cardinal Ximenes*, *The Duke of Alba in Spain*, *The Princes Orsini*, *De Mauléon*, *Dom Abbondio II.*, *Mother-joy and Mother-grief*, *The Orphan of Alkmaar*, *The Leyden Student in* 1593, *The Biography of the Landscape Painter Maria van Oosterwijk*, &c. Her last work appeared in 1865, in a magazine called *The Guide*, and will shortly (1866) come out in 2 vols. In 1845, the magistrates of Alkmaar gave her a handsome present, as a token of the high regard of her fellow-citizens. In 1851, she married Johannes Bosboom, a distinguished painter, and has since resided at the Hague. Besides other honours, her husband obtained the gold medal at

Brussels in 1842, and for paintings of churches, the large gold medal at the Paris Exhibition in 1855.

TOUSSAINT, FRANÇOIS DOMINIQUE, surnamed L'OUVERTURE, was born at Buda, in St Domingo, in 1743. His father and mother were both African slaves. When the French Revolution broke out, it found him in the position of coachman to a M. de Libertat, who appears also to have employed him as a sort of sub-manager of an estate for which he was himself the factor. In 1791, the French Convention passed the memorable decree, by which the rights of French citizens were given to people of colour. In the revolutionary strife which followed in St Domingo, T. was, for the next three years, conspicuous for his adherence to the cause of royalty and Catholicism; but the decree of February 4, 1794, which declared all slaves free, won him over to the side of the French republic. He joined their commander, Laveaux, by whom he was made a general of division. In 1793, in the midst of the troubles, the British had landed a force and taken partial possession of the island. Against them T. now proved himself an able and indefatigable enemy, bringing the whole of the northern division of the island under the dominion of the French republic. In 1795, in consequence of a conspiracy of three mulatto generals, Laveaux was arrested at Cape Town; but T., assembling his negroes, and uniting himself to the French force, quickly effected the release of the governor. The gratitude of Laveaux was very great; and, in 1796, the Commissioners of the Directory appointed T. chief of the army of St Domingo. Shortly after this event, General Maitland, the British commander, surrendered to him all the strong places which he had hitherto held in the island. This was followed in 1801 by the submission of the Spanish forts. The whole of St Domingo was then under the rule of Toussaint. His sway was vigorous and upright; and the agriculture and trade of the island both flourished under him. He was now at the summit of his prosperity. He assumed great state, though still retaining habits of personal simplicity. But a more powerful despot now found himself at leisure to interfere in the affairs of the island. During the peace of Amiens, Napoleon Bonaparte issued a proclamation re-establishing slavery in St Domingo. This was met by a counter-proclamation by T., issued on December 18, 1801, in which, while professing obedience, he shewed plainly that he meant resistance. A squadron of 54 sail of the line, under General Le Clerc, very soon made its appearance to enforce the edict of the first consul. It became apparent that T. had defied an enemy considerably too powerful for him. He was obliged to retire to the Morne of Chaos, where he hid his treasure. On February 17, 1802, he was proclaimed an outlaw. Finally, he agreed to surrender, and was received with military honours. He was afterwards treacherously arrested, and sent to Paris, where, after ten months of rigorous imprisonment, he died on April 27, 1803. It is difficult, from the conflicting testimony to form any correct estimate of the character of Toussaint. His temperament seems to have been romantic and imaginative, while results shew that his talent for organisation and administration must have been of a high order.—See *Histoire de l'Expédition des Français à Saint Dominique*, by Metral (Par. 1825); *Vie de Toussaint l'Ouverture*, by St Remy (Par. 1850); and *The Life of Toussaint l'Ouverture*, by Dr Beard (Lond. 1853).

TOWER OF LONDON, in feudal days, a powerful fortress; then, and long after, a state prison of gloomy memories; now, a government storehouse and armoury, and still, in some sense, a stronghold, is an irregular quadrilateral collection of buildings on rising ground adjoining the Thames, and immediately to the east of the city of London. The space occupied is between 12 and 13 acres, and the whole is surrounded by a moat of fair width, but no great depth. Usually, the moat is dry, but the garrison have the power of flooding it Seen from without, the moat is bordered within by a lofty castellated wall, broken by massive flanking-towers at frequent intervals. Within this wall rises a second of similar construction, but greater height; and within this, again, are the several barracks, armouries, &c.; and in the centre of all, the lofty keep or donjon known as the White Tower. This last, which nearly resembles Rochester Castle, and like it, was built by Gundulph, Bishop of Rochester, in the time of William the Conqueror, is the centre of interest and antiquity in the whole structure. Its walls are in parts 16 feet thick, and of solid masonry. This tower was the court of the Plantagenet kings. The various other towers are principally noteworthy on account of the illustrious prisoners who have pined in them, or left them for the scaffold. In the north-west corner of the quadrangle is St Peter's Chapel, now the garrison church. In another part is the Jewel-house, containing the crown jewels, or *Regalia*, comprising several crowns, sceptres, globes, and jewels of enormous value. Near this building is the Horse-armoury, a collection of ancient and mediæval arms and armour, the latter being exhibited in complete suits on wooden figures of men and horses. To the crown jewels and the armoury, visitors are admitted on payment of a small fee.

Early writers have alleged that Julius Cæsar first built the Tower of London as a Roman fortress; but there is no written evidence to prove the existence of any fortress on this site before the construction of the White Tower by Bishop Gundulph in 1078. Some earlier structure of the Saxon times appears to have been there, from the massive foundations which have been discovered in the course of subsequent erections; but of the nature of those buildings we know nothing. During the reigns of the first two Norman kings, the Tower seems to have been used as a fortress merely. In Henry I.'s time, it was already a state prison. That monarch and his successors gradually increased the size and strength of the ramparts and towers, until the whole became a stronghold of the first class for feudal times. The kings frequently resided there, holding their courts, and not unfrequently sustaining sieges and blockades from their rebellious subjects. Of the long list of executions for political offences, real or imputed, that of Lords Kilmarnock, Balmerino, and Lovat, after the Rebellion of 1745, was the last. Wilkes, Horne Tooke, and others have since been confined there; but happily, blood has ceased to flow since the existence of a living opposition has been found consistent with the safety of the government.

Not the least interesting memorials are the quaint and touching inscriptions cut by hapless prisoners on the walls of their dungeons.

In 1841, a very serious fire broke out in the Bowyer Tower, and extended to the armouries, causing the destruction of numerous modern buildings and many thousand stand-of-arms. At present, the Tower of London is a great military storehouse in charge of the War Department, containing arms and accoutrements for the complete equipment of a large army. The Mint and Public Records were formerly kept in it, but have now been removed to other buildings more suitable. Flamsteed, when first appointed Astronomer-royal, made his observations

from the summit of the White Tower; afterwards, he removed to Greenwich. It is needless to say that, viewed as a fortress, the Tower would be useless against modern arms.

The government is vested in a Constable, who has great privileges, and is usually a military officer of long service and distinguished mark; the Deputy-constable, also a general officer of repute, is the actual governor. He has a small staff under him, and the corps of Yeomen of the Guard, more commonly known as Beefeaters. In addition, a wing, and occasionally a battalion, of infantry is quartered in the barracks.—Bayley's *History of the Tower of London*, 2 vols. 4to; *Memoirs of the Tower*, by Britton and Brayley, 1 vol. 8vo (1831); *Memorials of the Tower of London*, by Lord De Ros (1866); W. H. Dixon, *Her Majesty's Tower* (1869).

TOWN-ADJUTANT, TOWN-MAJOR, officers on the staff of a garrison. They are often veteran officers, too much worn for field-service. The pay depends on the magnitude of the trust. The town-major ranks as a captain: the adjutant as a lieutenant. The duties of these officers consist in maintaining discipline, and looking after the finding of the batteries, &c.

TOWN-CLERK is the clerk to a municipal corporation, elected by the town-council. In England, he holds his office during pleasure, and his salary is paid out of the borough funds. His duties are: to take charge of the voting-papers in the election of councillors, to keep the records of the borough and lists of burgesses, and to perform a variety of miscellaneous duties imposed by sundry acts of parliament. —In Scotland, he holds his office *ad vitam aut culpam*, is the adviser of the magistrates and council in the discharge of their judicial and administrative functions, attends their meetings, records their proceedings, is the proper custodier of the records of the burgh, and keeper of the registers of sasines and deeds within it. Various important statutory duties are also assigned to him in relation to the registration of voters, the conduct of municipal elections, the valuation of lands and heritages, the registration of births, marriages, and deaths, the licensing of public-houses, &c. In the performance of a large proportion of these duties, he is independent of the town-council, who cannot make his appointment during pleasure, or attach to it any condition which might enable the council either to control him in the conduct of the business of his office, or withdraw from him any portion of his emoluments, so far as derived from fees. Being thus protected in the independent and impartial discharge of his functions as a public officer, he is bound to give extracts from the records in his custody without reference to the town-council, and is liable *personally* for the consequences of failure in any department of his duty. He is not, however, a magistrate in any sense, and cannot be held responsible for the obligations of the burgh, or for the omissions or neglect of the magistrates and council.

TOWN-COUNCIL is the governing body in a municipal corporation, elected by the community. The town-council administers the affairs of the borough in relation to its common property and to a variety of other matters, appointing the several officers required for this purpose. It is also charged with important functions in regard to police and sanitary matters; and the tendency of recent legislation is to concentrate in the council all matters of local administration. For the more effectual government of the community under its jurisdiction, the council is empowered to make by-laws, or private statutes, so far as not inconsistent with common law or public statute, or the constitution of the borough. One-third of the council go out of office every year, but are eligible for re-election at the annual elections in November. In all the corporate or borough towns of England (unless London, and a few other places specially excepted from the Municipal Corporation Act, 5 and 6 Will. IV. c. 76), the town-council consists of the mayor, aldermen, and councillors. The councillors vary in number from 12 to 64, according to the population of the town; and one-third of the number are aldermen. Every burgess who is enrolled in the burgess-roll—i. e. every inhabitant householder (who has been for three years, in respect of property, rated to the poor) in the borough, or within seven miles of the borough—is entitled to vote in the election of councillors. The council elects the mayor, who continues in office for one year. The aldermen are elected from the councillors, or from persons qualified to be councillors. In the larger boroughs, a person is not qualified to be a councillor unless he is worth £1000, or is rated for the support of the poor to the extent of £30 and upwards; but in the smaller boroughs, he is qualified if worth £500, or rated for the poor at £15.—In Scotland, the town-council consists of the provost (in burghs which have a provost), bailies, treasurer, and common councillors, with the addition, in Aberdeen, Dundee, and Perth, of the dean of guild, and in Edinburgh and Glasgow, of the dean of guild and convener of the trades. The election of councillors in the large proportion of the royal burghs is mainly regulated by the Act 3 and 4 Will. IV. c. 76, under which every person who possesses the qualification requisite for voting in the election of the member of parliament, and who has resided for six months previous to the 30th of June in or within seven miles of the royalty, is entitled to vote in the election of councillors. The persons entitled to be registered as parliamentary electors in burghs, are those who have, for not less than twelve months previous to the last day of July, been occupiers of any buildings within the burgh of the yearly value of £10, or the owners or husbands of the owners of such premises, though not occupying the same; provided always, that they are not in arrear of assessed taxes; that they have resided in the burgh, or within seven miles of it, for six months previous to the last day of July; and that they have not received parochial relief for twelve months. Joint occupants, whose house is of the yearly value of £10, are also entitled to be registered as voters. Every elector residing or carrying on business within the royalty is eligible as a councillor; but in burghs where burgesses exist, the person elected must be a burgess before induction. The number of councillors varies in different burghs. The larger burghs are divided into wards or districts, each of which elects its proportion of councillors, as the smaller burghs do the whole council. The provost (in burghs which have a provost), bailies, treasurer, and other office-bearers fixed by the set or usage of each burgh, are elected by the councillors, the provost and treasurer holding office for three years, and the other office-bearers for the unexpired period of their councillorship. Vacancies in the magistracy or council are filled up *ad interim* by the remaining members of council—the person so elected retiring at the succeeding annual election. In burghs returning members to parliament, but not royal burghs, the election of members of council is regulated by 3 and 4 Will. IV. c. 77, and 4 and 5 Will. IV. c. 86, the provisions of which are very similar to those above explained. In those more ancient royal burghs which, on account of the smallness of the population, are exempted from the provisions of the 3 and 4 Will. IV. c. 76, the election of

magistrates and councillors is conducted according to ancient practice.

Previous to the municipal reform acts in the reign of William IV., town-councils were generally close corporations; the members elected their successors; business was conducted in private; and corrupt practices, with a variety of other abuses, prevailed. In the present day, the town-council system is marked by defects of a different kind. Proceedings are very properly conducted publicly, but unfortunately much valuable time is often spent in making speeches with a view to being reported; on the plea of scruples of conscience, opportunities are taken to obstruct measures of the most salutary nature; subjects of a purely secular kind are judged with a sectarian bias; contrary to the principles of constitutional government, minorities will not submit gracefully to the decision of majorities, but by repeated and wearying manœuvres contend for the mastery; and, intimidated by the wranglings which too frequently prevail, the higher and more intelligent order of citizens will not allow themselves to be put in nomination for office. A leading error in the organisation of these bodies is perceived to consist in the large number of members; and it seems to be a growing opinion, that unless the number is everywhere greatly diminished, and a higher tone introduced into the proceedings, town-councils will inevitably lapse into that degree of public contempt from which they were rescued by the reform acts. On the public at large rests the responsibility of endeavouring to elevate the character of these civic corporations, the condition of which is in many places a heavy scandal and reproach.

TOWNSHEND, Charles, Viscount Townshend, English statesman, born 1676, was descended from a very ancient English family, which has been settled at Raynham, in Norfolk, since the reign of Henry I. His father, Horatio, had been a prominent member of the Presbyterian party before the Restoration, and having been one of the most forward in restoring the monarchy, was, by Charles II., made Baron in 1661, and Viscount in 1682. He died in 1687, when his son was only eleven years old. When he was of age to take his seat in the Upper House, he adopted his father's politics; but soon afterwards became a disciple of Lord Somers, and cordially co-operated with the Whigs. He was named by the Godolphin administration one of the commissioners for arranging the Union with Scotland, and was rewarded for his exertions by the captaincy of the yeomen of Queen Anne's Guard. He was then employed as a diplomatist; was joint-plenipotentiary with Marlborough at Gertruydenberg; and negotiated with the States-general the Barrier Treaty, which pledged the States-general to the Hanoverian succession, and England to procure the Spanish Low Countries for the United Provinces, as a barrier against France. In 1712, upon the formation of the Harley ministry, T. was dismissed from his places, and the Barrier Treaty was censured by the House of Commons, which voted that T. and all who had been concerned in the treaty were enemies to the queen and kingdom. This persecution raised him from the rank of a follower to the station of a leader. He maintained a close correspondence with the court of Hanover, and obtained the entire confidence of George I., who, on his accession to the throne of England, made him his chief minister. While George I. was still at the Hague, on his way to his new kingdom, he made T. Secretary of State, with power to name his colleague. He selected General, afterwards Earl, Stanhope, and formed a ministry entirely Whig in its party character. He strengthened it by the addition of Walpole, who, from being at first Paymaster of the Forces, was soon made Chancellor of the Exchequer and First Lord of the Treasury. The principal act of the government was the passing of the Septennial Bill, a bold and unconstitutional act. After the breaking up of the South Sea Bubble, and the deaths of Sunderland and Stanhope (q. v.), T. (1721) again became Secretary of State. But he was no longer the acknowledged leader of the Whigs. The superior talent of Walpole, his financial abilities, and his influence in the House of Commons, caused a change in the relative position of the two ministers, and converted those who been so long friends and colleagues, and who were also connected by ties of marriage (for T. had married Walpole's sister), into rivals and enemies. An open and unseemly quarrel broke out between them. They seized each other by the collar, and then laid their hands upon their swords. The interposition of friends prevented a duel; and T., resigning the contest, retired to Raynham, to cultivate his paternal acres. Walpole, on being asked the cause of his difference with his brother-in-law, replied: 'As long as the firm was Townshend and Walpole, all did very well; but when it became Walpole and Townshend, things went wrong, and a separation ensued.' T. introduced the turnip into Norfolk from Germany, and thus effected a most beneficial revolution in agriculture. He steadily refused to re-appear in public life, and died in a good old age, in June 1738, leaving behind him a high reputation for integrity and steady consistency in sound and constitutional principles of government.

TOWNSHEND, Charles, The Right Hon., English orator and statesman, was second son of the third Viscount Townshend, and grandson of the foregoing. He was born in 1725, and entered the House of Commons in 1747, as a supporter of the Pelham (Whig) Administration. His first great speech was against the Marriage Bill in 1753, which gained him a great reputation for eloquence. Upon the dissolution of the Whig government, the Earl of Bute gained him by the offer of the post of Secretary at War. On Bute's resignation in 1763, he was appointed First Lord of Trade and the Plantations. By this time, the versatility of his political career had obtained him the appellation of 'the Weathercock.' In the Chatham ministry of 1766, he accepted the post of Chancellor of the Exchequer, and leader of the House of Commons. When Lord Chatham, in a distempered state of mind, abdicated the post of First Minister T. broke loose from all restraint, and manifested the greatest vanity, ambition, and arrogance. George Grenville, smarting under the defeat of his favourite scheme of taxing America, on one occasion, in the middle of his harangue, turned to the ministers: 'You are cowards,' he said; 'you are afraid of the Americans; you dare not tax America.' T.'s fiery temper was kindled, and he exclaimed: 'Dare not tax America! I dare tax America.' Grenville retorted: 'I wish to God I could see it!' and T. replied: 'I will, I will.' He was not allowed to forget his pledge; and finding the notion of an American revenue agreeable to the court, and not unpalatable to the House of Commons, he proposed and carried those measures that led to the separation of the American colonies. T.'s wife was created a peeress, and he was about to be intrusted with the formation of a ministry, when he was carried away by a putrid fever (September 1767) in his 42d year. The difference between his contemporary reputation and his fame is very striking. He was ranked as an orator with Pitt. He was far more popular than the great commoner with the House of Commons; yet his name will not go down to

posterity, save in the annals of his time. Burke called him 'the delight and ornament of the House of Commons.' Macaulay speaks of him as 'the most brilliant and versatile of mankind,' who had 'belonged to every party, and cared for none.' Earl Russell describes him as 'a man utterly without principle, whose brilliant talents only made more prominent his want of truth, honour, and consistency.' He married Caroline, daughter and heiress of John, second Duke of Argyll and Greenwich, and widow of the Earl of Dalkeith, and had the discrimination to select Adam Smith as the tutor and travelling-companion of his step-son, the youthful Duke of Buccleuch.

TOWNSHIP, in English Law, means a division of a parish in which there is a separate constable, and for which there may be separate overseers of the poor.

TOYS. The making of toys forms a very important industrial occupation. Large numbers are made in London, Birmingham, and other places in Great Britain; but by far the largest number are made in Germany and Switzerland. Nürnberg is especially important in this respect, a large portion of the inhabitants of that town being engaged in the manufacture and trade in toys. The value of the toys imported annually into Britain is about £140,000.

TOXICO′LOGY is the term commonly employed in Medical Jurisprudence to designate the science of poisons. It embraces the physical and chemical history of all known poisonous substances, the methods of testing for them, their action on the living body, the *post-mortem* results which they occasion, and (according to some writers) the medical treatment that should be adopted. The word has a somewhat far-fetched origin. The Greek word *toxicon* signifies 'anything relating to *toxon*, a bow;' hence, with the word *pharmacon*, a drug, it was used to designate 'poison for smearing arrows,' and finally, *poison* generally.

TRA′CERY, the beautiful forms in stone with which the arches of Gothic windows are filled or traced for the support of the glass. These forms vary with every variety of Gothic architecture. Gothic windows were at first narrow, and were covered with a simple arch. Then two windows were grouped together, and an arch thrown over both. The space thus enclosed became part of the window, and was at first pierced with a circle,

Fig. 1.

quatrefoil, or other opening (fig. 1). When three or more windows were grouped under one arch, the *shield* or space in the arch became larger, and was pierced with apertures of various forms. In the early Pointed styles, these were usually circles filled with cinquefoils, trefoils, &c. (fig. 2). During the Decorated period the tracery became more varied in form, being composed of squares, triangles, and other forms, filled with foils, and having the appearance of being packed together (fig. 3). This

Fig. 2.

kind of tracery is called 'Geometric.' The windows of the transition from Decorated to Perpendicular had tracery of a more flowing character, while that of the Perpendicular Period (q. v.) became almost entirely composed of vertical lines. The

Fig. 3.

Flamboyant (q. v.) or contemporary style in France had tracery of a very different description—being as free and graceful as the other was straight and stiff.

Panels are often filled with tracery, the exteriors of the Perpendicular period being covered with such. The woodwork of all periods is filled with ornamental tracery.

TRACHE′A, The, is sufficiently described in the article Respiration. We have here only to notice those affections of this tube which require surgical or medical aid.

Foreign bodies occasionally pass through the larynx into the trachea. In cases of this kind, the patient who has had some foreign substance in his mouth which is supposed to have been swallowed, is seized with a convulsive cough, threatening suffocation, but subsiding after a time. The symptoms that then ensue vary with the weight and figure of the substance, and according as it is fixed or movable. A large and very irregular body may be impacted in the trachea, and may thus more or less obstruct the respiration on both sides of the chest; and this obstruction will probably soon be increased by the inflammatory products that are excited. A small heavy body will usually pass through the trachea into one of the bronchi (usually the right), or into one of its branches, obstructing respiration to a less extent.

'If the foreign body be allowed to remain, the progress of the symptoms presents much variety in different cases. Death may occur from spasm of the

glottis, or, the foreign body being propelled upwards into the rima, death may take place by its mechanically preventing the passage of air, or rupture of one of the cerebral blood vessels may be produced during one of the fits of coughing. At a later period the lungs may become congested and emphysematous, or bronchitis, pneumonia, or pleurisy may supervene.'—Gray's article on 'Injuries of the Neck,' in Holmes's *System of Surgery*, vol. ii. p. 306. Although inversion of the body, together with succussion and lateral movement of the larynx, has in some few cases been successful, it is now deemed advisable by the highest authorities to precede the attempt at removal by making an artificial opening into the windpipe. A free aperture is thus secured for respiration, spasm of the glottis is prevented, and the foreign body is commonly expelled through the artificial opening, or falls through the glottis into the mouth.

Rupture of the Trachea from external injury occasionally happens, and generally proves fatal in consequence of the rapid and extensive emphysema which usually ensues. It is too rare an accident to require a more special notice.

Wounds of the Trachea are sufficiently described in the article THROAT. With the exception of Croup (q. v.), there is no special disease of the trachea; and indeed in croup the trachea is seldom exclusively affected. Hence the term *Tracheitis*, used by some nosologists as synonymous with croup, is hardly warrantable. Similarly, in more advanced life, the trachea is doubtless often the seat of inflammation, but never the special and exclusive seat, and both the symptoms and treatment merge into those of bronchitis or laryngitis.

TRACHEO'TOMY AND LARYNGO'TOMY. The air-passages may be opened in three different situations—namely, through the crico-thyroid membrane (see LARYNX), when the operation is termed Laryngotomy; through the cricoid cartilage and the upper rings of the trachea, the operation being known as Laryngo-tracheotomy; and through the trachea, below the isthmus of the thyroid gland, constituting Tracheotomy proper. Laryngotomy and tracheotomy are more commonly performed than laryngo-tracheotomy, to which no further allusion is required. Laryngotomy is more quickly and easily performed, especially in adult males, and is less dangerous; tracheotomy is a more difficult, tedious, and dangerous operation, but in some cases (as, for example, where there is any necessity for introducing the forceps) must be selected. It is unnecessary to enter into details regarding the modes of performing these operations. When the operation is completed, a large curved tube to breathe through is inserted in the aperture, and secured round the neck with a tape.

A double tube or canula possesses many advantages, as, by withdrawing the inner one, which should slightly project at its lower extremity, it may be cleared of any mucus or blood that may have accumulated in it, without disturbing the wound. The calibre of the inner tube should always be sufficiently large to admit as much air as usually passes through the chink of the healthy glottis. The after-treatment is much the same as that required for wounds in the Throat (q. v.). 'Opening of the air-passages may be required,' says Mr Gray, 'in any case of disease or injury which produces mechanical impediment to the passage of air from the mouth into the trachea; in cases of foreign substances in the air-passages; and in some cases of suspended animation where artificial inflation of the lungs cannot be performed by the ordinary means.'—Holmes's *System of Surgery*, vol. ii. p. 317. In the case of a foreign body, its situation will determine the seat of the incision. Amongst the cases in which tracheotomy is, or may be, required, are cut throat, acute laryngitis, croup, diphtheria, chronic inflammation and ulceration of the larynx, necrosis of the laryngeal cartilages; tumours, excrescences, or epithelial growth within the larynx; tumours (bronchocele, abscesses, &c.) external to the larynx or upper part of the trachea, and impeding respiration by pressure, &c. It has also been recommended, but with little advantage, in hydrophobia, tetanus, and severe forms of epilepsy, with the view of relieving the suffocating spasms that occur in these diseases. Laryngotomy may advantageously be resorted to in cases of spasm of the glottis, in inflammation with œdema of the cellular tissue of the larynx, in inflammation of the tongue, in tonsilitis and pharyngitis, if the swelling is so great as to produce symptoms of suffocation, &c.

TRACHO'MA (derived from the Greek *trachus*, rough) is the term employed in ophthalmic surgery to designate a granular condition of the mucous covering of the eyelids, often accompanied with haziness and vascularity of the cornea. It is one of the most serious *sequelæ* of purulent Ophthalmia (q. v.).

TRA'CHYTE, a volcanic rock, principally composed of Felspar (q. v.), confusedly agglomerated in crystals, which are usually very small. Crystals of mica and hornblende are often also present, and more rarely crystals of augite, all embedded in a felspathic paste. The name is from the Greek *trachys*, rough; the rock being rough to the touch. *Trachytic Porphyry* is a porphyry essentially composed of trachyte. By some geologists, T. has been made the name of a class of volcanic rocks, in which Clinkstone, Obsidian, and Pumice are included.

TRACING-PAPER. See PAPER.

TRACTA'RIANISM, a remarkable and important movement in the English Church during the second quarter of the present century, which consisted in an endeavour to revive and bring into prominence the principles of antiquity, catholicity, and authority recognised in some portions of the Anglican formularies, in contrast to the Protestant sentiments long and widely prevailing. The name is derived from a series of papers entitled *Tracts for the Times*, published at Oxford during the years 1833—1841, hence called the 'Oxford Tracts.' The causes of this remarkable reaction it would be difficult to ascertain. The agitation of the question of Roman Catholic emancipation led, in some cases, to the study of Catholic theology, with a view to determine the real grounds of difference between the Roman and Anglican churches; and the religious and æsthetic tone of Wordsworth's poetry, still more developed in Keble's *Christian Year* (published in 1828), may have disposed some minds to sentiments to which it was akin. The lectures of Bishop Lloyd, when Regius Professor of Divinity at Oxford about 1823, on the Prayer-book and the Council of Trent, are considered to have led the way to the teaching of the *Tracts*. But the immediate origin of the movement appears to have been the alarm aroused for the interests of the English Church on the occasion of the suppression by the reform government of some of the Irish sees, and threatened alienation of Irish church property. It is said that about that time a meeting of clergymen took place at Hadley, in Suffolk, at which measures were concerted for opposing the alleged latitudinarian tendencies of the day, and restoring the High Church theology of the Anglican divines of the 17th century. The chief promoters of the movement were the Rev. John Keble, author of the *Christian Year*

Fellow of Oriel, and formerly Professor of Poetry at Oxford; Rev. J. H. Newman (q. v.), and R. H. Froude, also Fellows of Oriel; the Rev. E. B. Pusey, Regius Professor of Hebrew, and Canon of Christ Church; Rev. Isaac Williams, Fellow of Trinity, author of the *Cathedral and other Poems;* Rev. Hugh Rose of Cambridge; and others. The *Tracts* were issued anonymously, and, together with articles in the *British Critic* by the same writers, produced a great effect, especially among the clergy. Protestant principles were openly discountenanced, and tenets closely resembling those of the Church of Rome were boldly put forward. The doctrines of Apostolical Succession, Priestly Absolution, Baptismal Regeneration, the Real Presence, the Authority of the Church, and the value of Tradition, which had long lain hid in the language of the Prayer-book, were widely revived and taught, and caused much alarm in some quarters; though it must be admitted that those principles had always been held by a portion of the English clergy, and claimed to be only a fair exponent of the teaching of the church. The study of the Fathers and old divines, of church history and ancient liturgies, was greatly revived in the universities and among the clergy, and a host of publications inculcating with more or less extravagance the same views issued from the press. The movement proceeded, notwithstanding the general opposition of the authorities, till it culminated in the publication, by the Rev. J. H. Newman, of the Tract No. 90, which was designed to shew that much Roman doctrine might be held consistently with subscription to the Thirty-nine Articles. This being held to favour a 'non-natural' interpretation, was received with general condemnation, and led to the termination of the series, to the resignation by Mr Newman of the vicarage of St Mary's, Oxford, and subsequently to his secession, in 1845, to the Church of Rome. In this step he was followed by many of his friends and associates, though the other leaders of the movement have continued in the English Church. With Mr Newman's secession, the Tractarian movement terminated; but its effect remains in several visible results. 1. The first of these may be said to be the revival and strengthening of the High Church party, which still maintains to a great extent the principles advocated in the *Tracts;* and though checked by some judicial decisions, such as the Gorham (q. v.) judgment, in the endeavour to acquire exclusive power, has gained great and perhaps increasing influence in the church. 2. Side by side with the revival of Catholic doctrines, there has been a great development of ritual. The Tractarian movement was early marked by the introduction of various alterations in the mode of performing divine service, such as the use of the surplice instead of the gown, intoning the prayers and singing the responses, the elevation of the communion table into an altar, the substitution of low open benches for high pews—all of which, though claiming to be a restoration of ancient usage, and to have the authority of the law, were regarded with alarm as novelties, and as approximating to the Church of Rome. 3. Another effect of the Tractarian movement was the remarkable impulse given to the building and restoration of churches, and the revival of Gothic architecture, which has been manifested in all parts of England, and given a character to the ecclesiastical buildings of the present century which will mark them for ages to come. 4. The Tractarian movement has undoubtedly been the cause of the secession of many English clergy and laity, some of them men of considerable ability and distinction, to the Church of Rome, which has greatly increased the strength and influence of that communion in the country, and caused great scandal to the Protestant part of the population. Lastly, The movement may, however, be admitted to have produced a great increase of learning, piety, and devotedness among the clergy, and the establishment of colleges, sisterhoods, and other religious and charitable institutions.

TRA'CTION. See FRICTION.

TRADE, BOARD OF, a department of the British government, entitled 'The Lords of the Committee of Her Majesty's Privy Council appointed for the Consideration of all Matters relating to Trade and Foreign Plantations.' In 1660, Charles II created two separate councils for Trade and for Foreign Plantations, which, in 1672, were consolidated into one. The Board of Trade and Plantations, after being abolished in 1675, reappointed in 1695, and passing through various modifications, was again abolished in 1782, when its duties were transferred to the Secretary of State in so far as regarded the management of the colonies, and to a committee of Privy-council as regarded the other business. In 1786, the presently existing department was established by Order in Council, being a permanent committee of Privy-council for the consideration of all matters relating to Trade and the Colonies. The Board consists of a president and vice-president, together with the Lord Chancellor, the Archbishop of Canterbury, the First Lord of the Treasury, the principal Secretaries of State, the Chancellor of the Exchequer, the Speaker of the House of Commons, the Chancellor of the Duchy of Lancaster, the Paymaster of the Forces, the Treasurer of the Navy, the Master of the Mint, and such officers of state in Ireland as are privy-councillors in England. Practically, none of the members of the Board take part in its deliberations except the president and vice-president. The clerks of the Council are *ex officio* secretaries of the Board, but their duties as such are performed by two assistant-secretaries.

The functions of the Board of Trade are partly of a ministerial, partly of a judicial kind, and have of late years been greatly enlarged by a variety of statutes. The Board is charged with the general superintendence of all matters relating to the mercantile marine. It requires and considers reports made to its inspectors and other officers, and orders returns of various kinds regarding trade and navigation. In the exercise of a certain amount of control over marine boards, it is empowered to make regulations regarding the examination and qualifications of applicants for the position of master or mate of passenger-ships. Under 17 and 18 Vict. c. 104, it grants licences to persons to engage or supply seamen or apprentices for merchant-ships, decides on claims for wages, and investigates charges of misconduct and incompetency. In virtue of 14 and 15 Vict. c. 79, it appoints officers to inquire into and report on the condition of steam-vessels.

The supervision of railways and railway companies, both as to their original formation and their working, constitutes an important part of the duties of the Board of Trade. Railways were first subjected to government control by 3 and 4 Vict. c. 97 which conferred power on the Board of Trade to appoint inspectors of railways, to approve or disallow by-laws, to require returns of traffic, and to decide disputes between connecting lines. Further powers were added by 5 and 6 Vict. c. 55. In 1846, the increase of these duties, arising from the rapid extension of railways, led to the transfer of this department of the Board of Trade to a separate Board, created exclusively for the management of railway business; but in 1851 this latter Board was abolished, and its powers again transferred, by 14 and

15 Vict. c. 64, to the Board of Trade. Notices of applications for railway acts, with plans, are required to be deposited with the Board before any bill can be introduced into parliament; and before any railway can be opened for traffic, the permission of the Board must be obtained, on the report of an inspector. On the occurrence of an accident, notice must be given to the Board, which sends an inspector to inquire into the circumstances, and, on his report, the Board is empowered to take what steps are judged necessary for the security of the public.

A statistical department of the Board was established in 1832, whose province is to collect and publish tables containing classified information regarding the revenues, population, commerce, wealth, and moral and economical condition of the United Kingdom and its dependencies, to prepare a selection from the statistics of foreign countries, and a monthly account of trade and navigation. All applications made to the Queen in Council by companies or private persons for charters of incorporation, are referred to the Board of Trade; and among the functions committed to it by statute are the registration of joint-stock companies, and of copyright in designs. The Board is empowered by several local and personal acts to control the proceedings of the commissioners for regulating the employment of coal-whippers, and the discharge of coal-laden vessels in the port of London. In 1853, the Department of Science and Art, which owed its origin to suggestions made in the Second Report of the Commissioners for the Exhibition of 1851, and was at first a department of the Committee of the Privy Council on Education, was placed under the control of the Board of Trade; but in February 1856, it was retransferred, by an Order in Council, to the Committee of the Privy Council on Education.

The Board of Trade known as the Chamber of Commerce of the City of New York, was chartered in 1770. It interests itself in the consideration of questions relating to finance, currency, insurance, postal, and telegraph affairs, commerce, revenue, laws, lighthouses, railroads, canals, home trade and productions, pilotage, &c. Almost every enterprising city in the United States has its Board of Trade.

TRADE CORPORATIONS. See Corporation, and Joint-stock Company.

TRADE, Liberty to, is one of the rights incident to all persons by the law of England. So absolute is this right, that it is considered by courts of law to be an illegal and void covenant when a person, however deliberately, engages never to trade, for it is against public policy to support it. In the sale of the good-will of a business, such covenants are sometimes resorted to, in order to prevent the party selling a business from setting up immediately afterwards the same business, and so defeating the object of the transaction. Accordingly, in all such cases, the courts have arrived at the following result: If a person engage absolutely not to carry on a particular business anywhere, his engagement is void, and not binding; but it is competent for him to engage not to carry on a particular trade within a certain specified reasonable distance—as 20 or 30 miles—from a certain point, the reasonableness being estimated according to the nature of the trade and locality. If this engagement were not legal, it would be impossible to negotiate the sale of the good-will of a business. Subject to the above restriction, any person may carry on trade in any locality he pleases. But in the case of an alien enemy, a licence of the crown is necessary to enable a subject to carry on trade with him. It was also anciently a maxim, now obsolete, that none of the king's subjects could lawfully trade with a nation of infidels without the king's leave, because of the danger of relinquishing Christianity. Though, at common law, every man is free to carry on what trade he pleases, still there are a great variety of lawful trades which are subjected to certain restrictions, either ostensibly for purposes of revenue, or for the purpose of protecting the public from certain evils attending such trades. Thus, attorneys, publicans, manufacturers of cotton, &c., chimney-sweepers, and many miscellaneous employments, are subject to various restrictions. Formerly, also, the liberty to trade was considerably impeded by the ancient corporations and guilds; and it was a practice for these guilds to impose certain conditions on all persons who sought to trade in large towns, otherwise they were excluded from certain commercial as well as political privileges. As the by-laws which were the instruments of creating these restrictions were often authorised by charter of the crown, or grew up by ancient use and custom, then in harmony with the spirit of the age, the courts had a difficulty in treating them as illegal. But by the Municipal Corporations Act which passed for England in 1835 (5 and 6 Will. IV. c. 76), these restrictions were abolished. That act recited that, in divers cities, towns, and boroughs, a certain custom had prevailed, and by-laws had been made that no person, not being free of a city, town, or borough, or of certain guilds, mysteries, or trading companies, should keep any shop, or place for putting to show or sale any wares or merchandise for hire, gain, or sale; and it enacted that henceforth, notwithstanding such customs or by-laws, every person in any borough might keep any shop for the sale of all lawful wares and merchandise by wholesale or retail, and use every lawful trade, occupation, mystery, and handicraft, for hire, gain, sale, or otherwise within any borough. The city of London, however, was excepted from that act, and some of these old restrictions still flourish there. The law in Scotland and Ireland was also altered at the same time. The repeal of the Navigation Laws (q. v.) has also removed many restrictions on those who traded with ships.

TRADE-MARKS. The attaching of peculiar marks, by which manufacturers seek to distinguish their own productions from those made by other persons, is an important privilege, both as concerns the producer and the consumer; because no honest manufacturer will invent and apply a trade-mark to his wares, unless he is convinced that they possess some special excellence, which he wishes thus to make known; and it is desirable the public should have the benefit of such direction in the choice of their purchases as is thereby afforded. Nevertheless, until 1862, the law in Great Britain was in a very unsatisfactory state upon this subject, and the marks of celebrated manufacturers were pirated with the most reckless audacity both by British and foreign firms, in most cases, to enable them to pass off upon the public articles of very inferior character. For such infringement, the only remedy was to proceed by injunction from the Court of Chancery, a process which was far too troublesome and costly for the class of inventors most likely to be injured. The 'Merchandise Marks Act' of 1862 has remedied this evil, and simplified the whole matter, by making it a misdemeanour to forge or counterfeit any trade-mark, or falsely to apply any such trade-mark with intent to defraud, whether applied to a cask, bottle, stopper, vessel, case, cover, wrapper, band, reel, ticket, label, or any other thing, in or with which any commodity is sold, or intended to be sold. It is henceforth an offence to sell or expose, either for sale or for any purpose of trade

or manufacture, articles with forged or false trade-marks, under a penalty of a sum equal to the value of such articles, and a sum besides not exceeding £5, or less than 10*s*. Every addition to, or alteration and imitation of, any trade-mark made with intent to defraud—the intent being the essence of the offence in all cases—is to be deemed a forgery, and punished as such—viz., in addition to the penalties for misdemeanour, by the forfeiture of every instrument used for the purpose of the fraud, and of every article to which the false mark shall be applied. It is further made obligatory on every person who shall sell an article having a false trade-mark to give information as to where he procured it, on a demand for such information being made to him in writing; and in the case of refusing to do so, he can be summoned before a justice of the peace, and fined £5.

Trade-mark in the United States.—A symbol, emblem, or mark, which a tradesman puts upon or wraps or attaches in some way to the goods he manufactures, or has caused to be manufactured. It may be in any form of letters, words, vignettes, or ornamental design. Newly-recognized words may form a trade-mark. *Burnett* v. *Phalon*, N. Y. Superior Court, 1859. A common name of an article and of a place may by combination become a trade-mark. 2 *Bosw.*, N. Y., I. Alien merchants and traders have the same right and protection in regard to their trade-marks as citizens. 2 *Woodb. and M.* C. C., 1. In the examination of conflicting trade-marks the courts will judge as would the public, and mere variation of arrangement of a trade-mark, with secondary additions and omissions, will justify an injunction. Where goods with a false mark are made for a foreign market, an injunction will stop them, and injunctions have been granted where there have been parties of the same name and the similarity of trade-marks has been carried to the conclusion of simulation.

TRADE PROTECTION SOCIETIES are associations composed of merchants, tradesmen, and others, which have been formed for the promotion of trade, and for protecting the individual members from losses in their business transactions with each other, and with the community at large. They began to spring up about the middle of the last century—one of the first started in this country being the 'London Association of Guardians for the Protection of Trade,' which was established in 1776. The operations of these societies, during the earlier years of their existence, were confined chiefly to the compilation of registers of bankruptcies, insolvencies, and private settlements with creditors. The registers were formed thus: Each member informed the secretary of the society with which he was connected of the name, occupation, and address of each of his customers who became insolvent, with the amount of dividend his estate yielded; and latterly, the circumstances connected with such insolvency, whether it had been caused by recklessness or extravagance on the part of the bankrupt, or by innocent misfortune. These circumstances were carefully recorded, and the information thus collected having been found useful, means were taken to render the registers more complete. With this view, new sections were added to the registers, and special attention was directed to the exposure of swindlers, and persons who had been guilty of fraud or embezzlement. The information accumulated in the registers, though always accessible to such members as made inquiry at the offices of the society, was kept strictly private from all others. But the extraordinary development of commercial enterprise which took place in the early part of this century, added a new stimulus to the trade protection movement. The registers which the societies now printed and circulated among their members contained transcriptions from the following public records; viz., the records of the bankruptcy courts, registers of assignments and trust-deeds, bonds or warrants of attorney, bills of sale, judges' orders, protested bills, and decrees in absence. In addition to the diffusion of information of this description, the societies undertook to recover past-due bills and accounts for their members, to investigate the circumstances connected with bankruptcies and insolvencies, collect dividends, and perform the general agency business of their members—the whole being done under the direction of a committee appointed for this purpose. Committees were also appointed to scrutinise all measures affecting trade and commerce which might be introduced into parliament, and to promote legislation favourable to the commercial interest. The sphere of action of trade protection societies thus rapidly widened, and their utility kept pace with their growth. The older societies established offices and branches throughout the country; and new societies sprang up in the large provincial cities, which in their turn opened agencies and branches in every important town and village in their respective districts; and the various societies being in mutual communication, the machinery of the whole is available for the purposes of each.

TRADI'TION. See RULE OF FAITH; INFALLIBILITY.

TRADU'CIANISM (Lat. *traducianismus*; from *tradux*, a 'vine-layer' for propagation), one of the theories adopted for the purpose of explaining the production of the soul in the procreation of the human species. The theory known as traducianism is ascribed to Tertullian as its first author; and is elaborately explained and defended by him in his book *On the Soul*, written after he had lapsed into the Montanist heresy. In opposition to others who had held the theory of the pre-existence of souls, of which pre-existing souls one is divinely infused, or, by some natural affinity, is attracted into each fœtus so soon as it has been formed by generation in the procreation of man, Tertullian taught that souls are propagated by souls as bodies by bodies, and by the same or a simultaneous process. In another place he describes this origin of soul from soul as generation, and even of a class analogous to corporeal generation; and this more gross and material exposition of the theory of traducianism is sometimes called *Generationism*; which, however, is commonly looked upon as a totally distinct theory. A third hypothesis as to the origin of the soul suggested that, in the propagation of the human species, whenever a human body is formed by generation, the soul which is to animate that body is created, and by divine power infused into it. This theory is called *Creationism*. The discussion of these theories in the 4th and 5th centuries was much promoted by the controversies on Manichæism. See MANICHÆANS.

TRAFA'LGAR, CAPE, a low promontory on the south coast of Spain, about 29 miles west-north-west of Tarifa (q. v.), on the Straits of Gibraltar It is memorable for the great naval victory obtained off its shores by the British fleet under Nelson, over the combined fleets of France and Spain, under the French commander Villeneuve and two Spanish admirals. The British force consisted of 27 sail of the line, 4 frigates, 1 schooner and 1 cutter; the force of the French and Spaniards united amounted to 33 sail of the line, 5 frigates, and 2 brigs. It may be remarked that the largest of the enemies' ships carried 30 guns more than the

largest of the British ships. The engagement resulted in a splendid victory for the British, who captured nineteen of the enemies' ships. The victory, however, was gained at the cost of the life of the greatest of English admirals. See NELSON.

TRA'GACANTH. See GUM.

TRA'GEDY. See DRAMA.

TRA'GOPAN, a genus of birds of the family *Phasianidæ*, having the head crested, but naked on the cheeks and around the eyes; a horn-like caruncle projecting backwards from behind each eye; and a loose wattle, capable of being inflated, hanging beneath the bill. The tarsi are armed with a blunt spur in the male, unarmed in the female.

Tragopan, or Horned Pheasant (*T. satyrus*).

The species are few, and are natives of Asia. They are birds of beautiful plumage, somewhat resembling pheasants, but of more bulky form, and with rounded tails of moderate length. The first-known species (*T. satyrus*) has been called the *Horned Pheasant*. It inhabits the higher parts of the Himalaya, Tibet, and some of the mountainous provinces of China. The tragopans seem particularly deserving of attention, as capable of acclimatisation in Britain, and probably of domestication.

TRAIN-BANDS (or, more properly, TRAINED BANDS), a force of militia, and not differing essentially from that force, substituted by James I. for the old English Fyrd, or national militia. The train-bands of London were chiefly composed of apprentices; and their unruly doings formed the subject for many facetious plays and tales. In the civil wars, the train-bands sided with the Parliament; and Charles II. restored the militia on its old local footing.

TRAINING, applied in a Sporting sense, implies the acquisition of the most vigorous and perfect health, and is used alike in reference to men, horses, and dogs. An individual is said to be trained 'in condition,' when he has by certain processes rendered his frame as fit as it is possible for it to be, for performing some feat of strength or endurance—such as undergoing a pugilistic encounter, a wrestling match, or a trial of speed, or any other prolonged exertion. To accomplish this end, a long course of training is often gone through, in many instances of a very severe nature. It being necessary to divest the muscles of every particle of fatty tissue which can possibly be got off without direct injury to the health, it often happens that many pounds of flesh are required to be dispersed, and the most severe and continued exertion, the body being wrapped in thick suits of flannels, denominated 'sweaters,' is necessary. Constant hard and sharp exercise in this fashion, combined with rigid abstinence, and a strict regard to other established laws of the art, are a *sine quâ non* in getting the body into the height of condition. For example, however thirsty the person training may be, after perhaps ten miles' rapid walking in a triple suit of sweaters, he must drink but very sparingly, for although he may have taken off pounds of flesh by profuse perspiration, one glass of ale would undo the whole effect. Great attention to diet is necessary. Indeed, much of the system may, as a modern writer has aptly expressed it, be laid down in the resolute performance of the three cardinal virtues—temperance, soberness, and chastity. Almost the same course is pursued towards animals; and whether for hunting or racing, horses and dogs have to submit to a course of training to bring them into condition. Lately, the Turkish bath, as a means of procuring the necessary reduction of flesh without such excessive labour, has been found a most efficient ally in training. Out of condition, the muscles are flabby, confused, and coated with fat; the skin dead and lifeless; the eye dull and heavy; the lungs labouring, and the movements slow. In condition, the muscles stand out hard, clear, and defined; the tendons shew like cords; the skin is clear and ruddy; the eye bright; the lungs play with unrestrained freedom; and the whole frame is endued with vigour and perfect activity. Animals, from their less artificial existence, require far less training than men to bring them into condition.

TRA'JAN'S COLUMN, a celebrated column at Rome, which was reared, 114 A.D., by the Roman senate and people, in honour of the Emperor Trajan. It is considered not only the greatest work of its architect, Apollodorus, but one of the noblest structures of its kind ever erected. The pedestal is covered with bas-reliefs of warlike instruments, shields, and helmets; and a very remarkable series of bas-reliefs, forming a spiral round the shaft, exhibits a continuous history of the military achievements of Trajan. These are in excellent preservation, and, independently of their beauty as works of art, they are invaluable as records of ancient costume. A spiral staircase in the interior of the column leads to its summit. The height of the entire column is 132 feet. It still stands erect in all its ancient beauty amid the ruins of Trajan's forum. The summit was originally crowned by a colossal statue of the emperor, which has been incongruously replaced by one of St Peter.

TRAJAN'S WALL, a line of fortifications stretching across the Dobrudscha from Czernavoda, where the Danube bends northwards, to a point of the Black Sea coast near Kustendji. It consists of a double, and in some places a triple, line of ramparts of earth, from $8\frac{3}{4}$ to 11 feet in height on the average (though occasionally it attains an altitude of $19\frac{1}{2}$ feet), bounded along its north side by a valley, which, being generally marshy, and abounding in small lakes and pools, serves admirably the purpose of a fosse. This valley was long erroneously supposed to have been at one time the channel by which the Danube emptied itself; and a scheme for utilising it by the construction of a canal to provide a more commodious water-communication with the Black Sea, in lieu of the long and troublesome navigation by the Sulina mouth, has been frequently mooted, and is undoubtedly quite practicable; but the cost of the undertaking has hitherto been a bar to its execution. During the war of 1854, Trajan's Wall became an important line of defence on the invasion of the Dobrudscha by the Russians, and the invaders were twice defeated in their attempts to pass it—at Kostelli (10th April) and Czernavoda (20—22d April).

TRAJA'NUS, MARCUS ULPIUS, Roman emperor, was born at Italica (Alcala), near Seville, 18th

September 52 A.D. He was descended from a family which was probably of Roman origin, and was early trained to arms, becoming a prominently successful leader in the Parthian and German campaigns, during the reigns of Titus and Domitian. He was rewarded for his valuable services by promotion to the offices of prætor and consul (91 A. D.), and was ultimately adopted (97 A. D.) by Nerva (q. v.) as his colleague and successor. T. became sole ruler in January of the following year, and celebrated the event of his accession by the usual largess to the soldiers, which gift his liberality prompted him to extend also to the Roman citizens and their children; and he made large provision out of the imperial treasury for the upbringing of the children of poor freemen in Rome and other Italian towns, with the view of encouraging the increase of the population. In 101 A.D., Rome, for the first time, beheld its emperor leading forth his legions in person on a career of conquest, when T. set out on his first campaign against the Dacians who had exacted tribute from Rome since Domitian's time. The struggle was long and destructive; the emperor's opponents were valiant warriors, and headed by an able leader, their monarch, Decebalus; but the Romans at last gained a decisive superiority; and in a subsequent campaign (104—105) completely subdue their opponents, whose country thenceforth became the Roman province of Dacia, and was secured by partial colonisation. This conquest, the first since the death of Augustus, was celebrated, on T.'s return to Rome, by a triumph, and by games on a most extensive scale, which continued for four months. Thirst for dominion again impelled T. to the east in 106 A.D. Landing in Syria, he marched northwards, received on his way the submission of numerous princes, possessed himself of Armenia, which he made a province of his empire, and hugely gratified the Roman senate with long lists of monarchs, never before heard of, who had bowed to their sway. The record of the events of the next seven years of T.'s reign is extremely defective, the few notices in Dion Cassius and others being insufficient for the construction of a consecutive narrative. In 115 A. D., he again set out from Syria, directing his march this time against the degenerate Parthian Empire; took Ctesiphon almost without a struggle; and descending the Tigris, and subduing the tribes on both banks, became the first and only Roman general who navigated the Persian Gulf. On his return, he found that, like the bent reed which recovers its position when relieved from pressure, the peoples of Mesopotamia, North Syria, and Arabia required to be again and more thoroughly subdued. This being done, and Parthia again conquered, T., sinking under a combination of dropsy and paralysis, which had long afflicted him, attempted to reach Italy, but was overtaken by death at Selinus, in Cilicia, August 117. Though most of T.'s reign was spent in the gratification of his warlike ambition, the internal administration was far from being neglected; the administration of justice was vigorous and impartial; that of finance was equally acceptable; informers (*delatores*) were severely punished, and peculating governors of provinces rigorously prosecuted. The improvement and beautifying of Rome—a favourite occupation of the emperors—was carried on: the empire was traversed in all directions by new military routes, canals and bridges were constructed, new towns built, the Via Appia was restored, the Pontine Marshes partially drained, the magnificent 'Forum Trajani' erected, and the harbour of Centum Cellæ (Civita Vecchia) constructed. Even if there were not abundant evidence of the sincere desire of T. to increase the comfort and happiness of his subjects, the customary wish formally uttered on the occasion of an emperor's accession, that he might be 'happier than Augustus, better than Trajan' (*Augusto felicior, Trajano melior*), would of itself suffice for proof. During T.'s reign, a persecution of the Christians, of a mild character, took place; and taking into account that T. almost necessarily shared the general belief that Christianity was a perilous species of fanaticism, his conduct towards them deserves, perhaps, to be entitled moderation.

TRAJE'CTORY, in Mathematics, is any plane curve which cuts at a given angle a series of plane curves of the same species and having a common origin. In Mechanics and Astronomy, it denotes the path described by any body projected into space, and continuously acted upon by constant or varying forces; thus, the trajectory of a body projected obliquely for a little distance above the earth, is approximately a parabola (it would be accurately so, were space void, and the centre of gravity of the earth infinitely distant), and the trajectories of the planets are approximately ellipses; the term, however, was long, in astronomy, exclusively applied to the paths of comets.

TRALEE', a seaport and parliamentary borough of Ireland, chief town of the county of Kerry, stands on the river Lee, about a mile from the point at which it enters the sea, 162 miles west-south-west from Dublin, with which it is connected by the Great Southern and Western and Killarney Railways. The pop., in 1871, was 9512, of whom 8567 were Roman Catholics, and 945 Protestant Episcopalians; in 1881, 9664. The first origin of T. was due to the building of a castle, and the foundation of a Dominican convent by the Geraldine family, in 1213; and somewhat later, a considerable House of the order of Templars was established. The borough is now under the management of commissioners, who dispose of a revenue amounting, in 1862, to £2226. It returns one member to the imperial parliament. The town is well built, and possesses many public buildings. A large traffic in grain and agricultural produce is carried on, the annual exports amounting to £200,000, and imports to about £150,000. There is a ship-canal, by which vessels discharge their cargoes close to the town.

TRAM. See SILK.

TRA'MMEL-NET, a kind of net resembling the drift-net used in the Herring-fishery (q. v.), but anchored and buoyed at each end, the back-rope supported by small cork-floats, and the foot-rope kept close to the ground by weights. The length varies from twenty to three hundred yards. A variety of trammel-net, chiefly used in the west of England and in Guernsey, consists of three long nets fastened together at top, bottom, and ends. The two outer nets are each five meshes deep, the meshes ten inches square; the middle net is twice as long and deep as the outer ones, but the excess at the edges is gathered in and united all round with the other nets. The outer nets stand with their meshes square and opposite one another, and a fish, in passing through the first net, meets the second or middle net—which, being slack, yields to the pressure—and is carried through the opposite large mesh of the third net into a loose bag or pocket, from which it cannot escape. This net is much used for taking red mullet, and in some parts of Cornwall is called a *tumbling-net*.

TRAMWAY. See RAILWAYS.

TRANCE, or **MORBID SLEEP**, differs from natural repose in duration; in profound insensibility

to external impressions; in following excitement and the exaltation of certain instincts, chiefly the religious and amative, rather than fatigue or exhaustion; and in being the concomitant or symptom of diseases of the nervous system. The attitude, aspect, lowered respiration, and circulation of the entranced, resemble those of the sleeper. But there are many exceptions to this observation. A girl who remained dormant for 13 years, although she grew from a child to a woman in that time, was corpse-like in appearance, had locked-jaw, and there was all but a total suspension of the signs of life. But while an individual cannot be roused from this condition by the most powerful stimulants, an electric shock, or even, it is affirmed, by a surgical operation, thought or dream goes on uninterruptedly, and is more continuous and coherent in character than what takes place in ordinary sleep. So connected and real do these visions appear to the ecstatic, that they are generally accepted as true events, revelations, or impressions, received during a brief visit to another world. Trance has occurred epidemically during periods of great religious fervour and superstition; and whole classes of persons are described as having preached while asleep, in the insurrection of the Cevennes. A similar phenomenon has recently (1865) been observed in those affected by hysteromania at Morzine in Savoy. The affection has been divided, according to the intensity of the symptoms, into (1) *Death-trance*, where neither the heart nor lungs act; where the temperature of the body falls; where no sustenance is taken, and the inner dream-life is the only vestige of vitality. Engelbrecht, who was subject to trance, wrote a book descriptive of this inner life, during which he believed himself to be transported to supernatural, if not to heavenly regions. (2) *Trance-coma*, where the breathing and action of the heart are feeble, but perceptible; the joints flexible; but where the external senses are not awake, and where the patient cannot be roused. (3) *Trance-sleep*, where, except in the insensibility to external stimuli, and in the length of the suspension of volition, little abnormal is noticed. As these states often succeed hysteria, nervous and other diseases, the bodies of the supposed dead are for a time, in certain countries, so placed as to be watched, and in circumstances favourable to resuscitation.—Mayo, *On the Truths contained in Popular Superstitions*, p. 88; Figuier, *Histoire du Merveilleux dans les Temps Modernes*, t. ii. p. 38; Dendy, *The Philosophy of Mystery*, p. 367.

TRA′NI, a maritime city of Southern Italy, in the province of Terra di Bari, 25 miles north-west of the town of Bari. Pop. about 25,000. It is surrounded by a wall with towers and moats, and entered by three gates. T. is an archbishop's see, and has a handsome cathedral, convents, a court of appeal, a theatre, and a strong castle. The streets are wide, well built, and paved with flagstones. There is a handsome square. A considerable trade in oil, wine, corn, and cotton, which last is also manufactured here, is carried on.

T. comes first into notice when it submitted to the Normans in 1053. It was then the chief town of a vast county, and was an important harbour in the time of the Crusades. Under the kingdom of Italy, it has again begun to prosper, and promises once more to become an emporium of the commerce of the Levant, as it was in the middle ages.

TRANQUEBA′R, a corruption of *Tallangambadi*, a seaport town on the east coast of British India, 155 miles south of the city of Madras. It stands on a small bay, and is backed by a well-wooded and cultivated country; is a healthy station, much cooler than Madras, and has therefore been made a convalescent dépôt. The town is surrounded by walls, with bastions, and is further protected by the fort of Dansborg. The territory of T. embraces 15 sq. m., and produces rice, the cocoa-nut and other palms, the mango, and a variety of fruits. The town itself contains about 25,000 inhabitants. The territory passed finally into the hands of the English—the Danes having been its former possessors—in 1845.

TRANSCAUCA′SIA, the tract of territory belonging to Russia, and extending between the Caucasus (q. v.) on the north, and Turkey in Asia and Persia on the south. This name, however, has no practical geographical significance, as the Russians include the territory which it denotes in what they call the Caucasus, which comprises the governments of Stavropol, Tiflis (q. v.), Koutaïs, Elizabethpol, Bakou, and Erivan, and several territories. The area of the Caucasus is 168,880 square miles; pop. (1867) 4,661,824.

TRANSCENDE′NTAL, TRANSCENDENT (*transcendentalis, transcendens*), words employed by various Schoolmen, in particular Duns Scotus, to describe the conceptions that, by their universality, rise above or transcend the ten Aristotelian Categories (see CATEGORIES). Thus, according to Scotus, *Ens*, or Being, because it is predicable of Substance and Accident alike, of God as well as of the World, is raised above these by including or comprehending them; it has the same relation to the sum of the Categories, as the *summum genus* to the various genera within a single category—Relation (*summum genus*) to the classes of Related things (included genera). Further, the predicates assumed by Scotus to belong to *Ens*, or simple existence; viz., the One, the True, the Good—*Unum, Verum, Bonum*—are styled transcendent, because applicable to *Ens* before the *descent* is made to the ten classes of real existence. In later times, since Kant, the word Transcendental has been largely used as equivalent to the philosophical meaning of *à priori*. See COMMON SENSE, INSTINCT.

Between the hitherto convertible terms, Transcendental and Transcendent, Kant himself drew a distinction, of considerable importance in understanding his own system. By the word 'Transcendental,' he designates the various forms, categories, or ideas assumed to be native elements of human thought; implying that, although they are not products of Experience, they are manifested only in experience; such are Space and Time, Causality, &c. The word 'Transcendent,' Kant reserves for those among the transcendental or *à priori* elements that altogether transcend experience. They may seem to be given in experience, but they are not really given. Such are the 'Ideas of the Pure Reason,' God, an Immaterial Soul, &c. Transcendental elements, when legitimately applied to experience, as Causality and Relation, are called Immanent.

TRA′NSEPT, the projecting wings on the north and south sides of a church, forming the smaller arms of the cross, in the ground-plan of cruciform churches.

TRA′NSFERENCE, in the Law of Scotland, means the step by which a pending suit is transferred from a person deceased to his representative.

TRANSFU′SION OF BLOOD has been regarded as a recognised and legitimate operation in obstetric surgery since the year 1824, when Dr Blundell published his well-known work, entitled *Physiological and Pathological Researches*. The operation had, however, been vaguely known to the

medical profession for the last four centuries; and there are obscure allusions in the Roman poets, which would seem to indicate that it was practised as early as the Augustan age:

> Ut repleam vacuas juvenili sanguine venas.
> *Ovid.*

The earliest authentic case on record is, so far as we know, that of Pope Innocent VIII., who was unsuccessfully operated on in April 1492. 'The vital powers of Innocent VIII. rapidly gave way; he had for some time fallen into a kind of somnolency, which was sometimes so profound that the whole court believed him to be dead. All means to awaken the exhausted vitality had been resorted to in vain, when a Jew doctor proposed to do so by the transfusion, by a new instrument, of the blood of a young person—an experiment which had hitherto only been made on animals. Accordingly, the blood of the decrepit old pontiff was passed into the veins of a youth, whose blood was transferred into those of the old man. The experiment was tried three times, and at the cost of the lives of three boys, probably from air getting into their veins, but without any effect to save that of the pope.'—Villari's *Life of Savonarola.* Although Libavius, in 1615, accurately describes the operation, there is no evidence that he ever practised it. Passing over various experiments by Wren and Lower (both of Oxford) in the transfusion of blood from one animal to another, we find Denys of Montpellier, in June 1667, injecting the blood of calves into the veins of a young man who had been much weakened, and had become torpid and slightly dropsical, in consequence of repeated bleedings. The first operation restored him to perfect health. Subsequent cases of his gave rise to a most virulent controversy, which ended with the decision, 'that for the future, no transfusion should be made upon the human body but by the approbation of the physicians of the Parisian faculty.' In November of the same year, Lower publicly made a similar experiment, which seems to have been successful; and in the following year, Riva and Manfridi repeated the experiment in Italy. But the operation, although thus fairly started, soon fell into obscurity, doubtless from a want of success, due partly to the blood of calves and sheep, instead of human blood, being used, and partly to hopeless cases of old age and decrepitude being selected for its application.

At the present day, transfusion is an operation which is almost always restricted* to cases of profuse hæmorrhage in connection with labour; and as Dr Playfair, in his excellent *Handbook of Obstetric Operations* (Lond. 1865), observes: 'The benefits derived from it are probably twofold: 1. The actual restitution of blood which has been lost; and 2. The supply of a sufficient quantity of blood to the heart, to stimulate it to contraction, and thus to enable the circulation to be carried on until fresh blood is formed. Its stimulant action is probably of far the most importance; and if the operation is performed before the vital energies are entirely exhausted, the effect is most marked, and indeed may be said to be almost unfailing.'—Pp. 212, 213. Blundell was in error in believing that the blood of animals of the same species was essential; Dr Brown-Sequard having since shewn that the blood of various animals can be used indiscriminately, provided only certain precautions are taken; and the important* discovery has recently been made by Panum, that defibrinated blood is in every respect as well suited for the operation as pure blood.

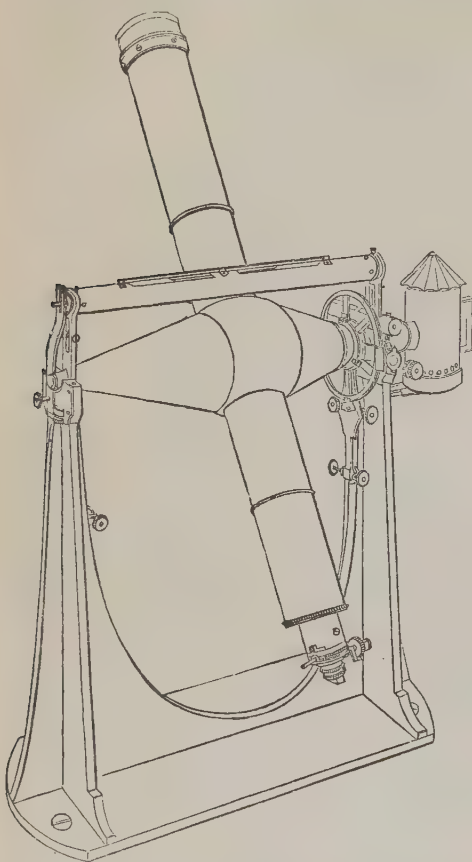
'The cases suitable for the operation,' says Dr Playfair, 'are those in which the patient is reduced to an extreme state of exhaustion from hæmorrhage during or after labour or miscarriage. The operation will not come into contemplation until other and simpler means have been tried and failed, and when the symptoms indicate that life is on the verge of extinction.' The value of the operation in suitable cases is proved by statistical evidence. Mr Soden of Bath has recorded 36 cases, in 29 of which the patients were rescued from an apparently hopeless state; and out of 57 cases recorded by Professor Martins of Berlin, 43 were entirely successful, and 7 temporarily so. Of the various syringes that have been invented for this operation, Dr Playfair gives the preference to that of Dr Graily Hewitt. The blood to be injected should be taken from the arm of a strong and healthy man who can spare a sufficient quantity, since a change of persons leads to delay, and should therefore be avoided. Generally speaking, from four to six ounces of blood are sufficient, but more may be required. It would be out of place to enter, in these pages, into details regarding the mode of performing the operation. They are fully described in Dr Playfair's work.

TRA'NSIT-INSTRUMENT, one of the most important of astronomical instruments, consists of a telescope fixed to a horizontal axis, so as to revolve in the plane of the meridian, and is employed, as its name denotes, in the observation of the meridian transits of the heavenly bodies. The axis, which is the most important part of the instrument, and thus demands the utmost care in its construction, consists of a hollow sphere or cube, to opposite sides of which are tightly fastened the bases of two cones in whose apices the pivots are screwed; the sphere or cube is pierced for the admission of the telescope, which is firmly soldered at right angles to the axis. One of the pivots is hollowed so that a stream of light can be directed from a lantern half way along the interior of the axis, and through an aperture in the side, into the telescope tube, where, being received by an annular mirror, set at 45° to the axis and telescope tube, it is directed to the eye-piece, and brilliantly illumines the field of view, while the annular form of the mirror prevents any interference with the passage of rays from the object under observation to the eye. The pivots must be very carefully turned to a perfectly cylindrical form, and fitted into the instrument, so that their axes are accurately in line. One extremity of the axis carries one and sometimes two small graduated circles, each supplied with index, clamping screws, and vernier; these circles are capable of indicating angular measures to within 1′ or 2′. The pivots rest on massive blocks of stone or other stable material which is little affected by change of temperature, stability being the great mechanical essential of the instrument. This condition satisfied, there are three adjustments necessary before a transit can be observed: the axis must be horizontal; the line of collimation must be at right

* A case has lately been recorded in which it proved successful in a case of coma from the fumes of carbonic oxide and carbonic acid; and it is not improbable that it may again come into more general medical use.

* Dr Markham has, we believe, suggested the trial of transfusion of blood in cases of the cattle disease. As it would be impossible, without danger, to bring a healthy animal in contact with a diseased one, the value of Panum's discovery, provided the proposed remedy be successful, is obvious. The blood of healthy oxen, killed for the market, could be defibrinated by whipping and straining, and would remain fit for injection, when raised to the normal temperature, for many hours.

angles to the axis of motion; and the latter must be placed so as to point accurately east and west. On the perfection of the first two of these adjustments depends whether the telescope sweeps over a great circle of the sphere, and the third is necessary to insure that this great circle shall be the meridian of the place of observation. These adjustments can never be made quite perfect, and the usual mode is to investigate the amount of error in each, and allow



Transit Instrument.

for it in the apparent result. To note accurately the instant of time by the astronomical clock at which the object (e. g., a star) is seen to pass the centre of the field of view, is the essential part of a transit observation. The most effective method is to register the beats of the clock by an apparatus, which, at the end of each oscillation of the pendulum, marks a dot upon a uniformly moving slip of paper. This is effected by the agency of electricity, and is one of its most valuable contributions to astronomical science. At a certain point in each oscillation of the pendulum, it becomes part of a complete galvanic circuit, the contact being immediately broken by its progression in its oscillation; and it is at these points that the galvanic agency causes the dot to be made. The instant of a transit's occurrence is similarly noted by the observer, who, by a tap on a break-circuit key, fastened to the side of the transit-instrument, causes the graver to make an extra dot; and the distance of this dot from the previous seconds one, compared with the distance between two seconds dots, gives the time accurately almost to $\frac{1}{100}$th of a second. Various ingenious modes of registering have been proposed, all founded on the above principles. It is from the times of transit of the several heavenly bodies thus accurately observed, that their right ascensions are determined.

The transit-instrument was invented by Römer about 1690, and first described in 1700, in the *Miscellanea Berolinensia*, vol. iii. One was erected in Greenwich Observatory by Halley in 1721; but it was little used till 1742. The present instrument in that observatory is by Troughton, and was erected in 1816.

TRANSI'TION, a term employed at first by Werner to designate rocks having a mineral character intermediate between the highly crystalline or metamorphic rocks and ordinary sedimentary deposits. As these rocks, in the region where the Wernerian classification originated, had a definite relation to the inferior and superior strata, and contained a uniform series of fossil remains, the term gradually came to have a chronological meaning. It was employed to designate similar deposits wherever they occurred. But a more enlarged view of the sedimentary deposits in the different countries of Europe, exploded the idea of a transition either in mineral structure or organic contents being characteristic of any set of beds, and caused the Transition series to be more accurately classified as Cambrian, Silurian, and Devonian strata.

TRA'NSITORY ACTION, in the Law of England, is used, in contradistinction to Local Action, to denote that the particular action may be tried in another county than that in which the occurrence arose.

TRANSLA'TION OF MINISTERS, in the Law of Scotland, means the removal of a minister from one parish benefice to another.

TRANSMIGRA'TION, or the passing from one place, state, or condition into another, means, in the theological acceptation of the term, the supposed transition of the soul after death into another substance or body than that which it occupied before. The belief in such a transition is one of the most important phases in the religions of mankind. It was common to the most uncivilised and the most civilised nations of the earth; it was the object of fantastical superstition, as well as that of philosophical speculation, and it is the property of both ancient and modern times. Its basis being the assumption that the human soul does not perish together with the body, it could belong to those nations only which had already conceived an idea of the immortality of the soul; but in proportion as such an idea is crude or developed, as it is founded merely on a vague fear of death, and a craving for material life, or on ethical grounds, and a supposed causal connection between this and a future life, the belief in transmigration assumes various forms, and influences more or less the actions of men.

The lowest forms of this belief are probably those met with among several tribes of Africa and America, which hold that the soul, immediately after death, must look out for a new owner, and, if need be, enter even the body of an animal. Several negro tribes entertain this belief; they assume that the soul will choose with predilection the body of a person of similar rank to that of its former owner, or a near relation of his; and they frequently therefore bury their dead near the houses of their relatives, in order to enable the souls of the former to occupy the newly-born children of the latter, and the princely souls to re-enter the princely family; and until the soul is thus accommodated, milk, brandy, and food are placed on the grave of the deceased, to keep it, as it were, from starving; and sometimes

holes are dug in the grave, to facilitate the soul's egress from it. In North America, some tribes slaughter their captives, to feed with their blood such souls in suspense. The negro widows of Matamba are especially afraid of the souls of their husbands, for at the death of these they immediately throw themselves into the water, to drown their husbands' souls, which otherwise, as they suppose, would cling to them. The natives of Madagascar seem to have invented a kind of artificial transmigration, for in the hut where a man is about to die, they make a hole in the roof, in order to catch the outgoing soul, and to breathe it into the body of another man on the point of death. From these and instances of a similar kind, it will be seen that nations which entertain such a belief in transmigration, assume that the souls of the deceased must continue to dwell upon earth, and that one human being may be possessed of several souls. With them, the final destination of the soul is a matter of comparative indifference; its transition from one body into another a mere matter of chance, devoid —apparently, at least—of any ethical principle, and therefore without any moral effect on the living, except, perhaps, that of a stolid indifference to death, as often manifested in the plantations of the West Indies, where negroes hang themselves, in the belief that their souls will migrate into other countries, and there enjoy a happier life.

Another, more poetical, and in some respect also, more ideal form of this belief in transmigration, is that which occurs in Germanic mythology, and is still entertained in some parts of Germany and England. According to it, the soul, before entering its divine abode, assumes certain forms, or animates certain objects, in which it lives for a short period. Thus, it is supposed to enter some flower or tree, a rose, a vine, a plantain, a pine-tree; or to nimate a butterfly, a pigeon, and sometimes also— a person dies while enchanted or sleeping—a serent, a weasel, or a mouse. The most popular form f these supposed transmigrations, however, is that of a pigeon, a representation of which bird, therefore, often occurs on the oldest tombstones. When the robber Madej, for instance, under an appletree confessed his crimes, one apple after another, transformed into a white pigeon, flew into the air. They were the souls of the persons murdered by him; only one apple remained, because he had not yet confessed the murder of his father; but when he did so, also the last apple—the soul of his father —assuming the shape of a gray pigeon, flew after the rest.

Different from this kind of belief in transmigration is that which is based on ethical grounds. It proceeds from the theory, that the human souls, being of divine essence are originally pure, but during their earthly career, lose of their purity; being destined, however, to regain their original quality, are reborn again and again, until they have become free from fault, and thus worthy of re-entering the place of their origin.

A belief of this nature was entertained by the old Mexicans, and probably also the Druids. It is met with in a more developed form with the old Egyptians; but its real importance it obtained as a tenet of the religion and philosophy of the Brahmanical Hindus and the Buddhists, whence it passed into the doctrine of several philosophers of ancient Greece, and into that of some Jewish and Christian sects.

The ethical and philosophical value which such a belief may have, is necessarily relative. It will depend on what a religion or philosophy may call right or wrong, virtue or sin; it will likewise depend on the notions which religion or philosophy may entertain on the origin of the human soul, on the cause of its first birth, and on its ultimate destination, whether this destination is the merging of the soul into the essence of the Creator, or a personal immortality; and again, the mode in which such a personal immortality is conceived, will also necessarily influence the mode in which transmigration is supposed to take place.

Where the ideas on these questions have remained crude, the idea of transmigration, too, is but of little ethical or philosophical worth. The old Mexicans imagine that the gods *Ometeuctli* and *Omecihuatl* create in heaven the soul of a child destined to be born, and that by its acts on earth it will either ascend to the abode of the highest felicity, or remain in an intermediate heaven, or fall to hell. The highest goal, situated in the house of the sun with the god *Huitzilopotchli*, is full of pleasure and joy, and is attained merely by the souls of fallen warriors, or those who died in captivity, and women dying in childbirth. The second or intermediate heaven, cool and pleasant, but of moderate enjoyments, falls to the lot of men who are not wicked. The wicked, however, go to the abode of darkness; and in darkness consists their punishment. But those entitled to the second heaven may, if they like, also return to earth, in order to qualify themselves for the highest heaven, if such is their aspiration.

Of the Druids, it is told by classical writers that they believed in the immortality of the soul, and in its migration after a certain period subsequent to death. Little is known of the manner in which they imagined such migrations to take place; but to judge from their religious system, there can be no doubt that they looked upon transmigrations as a means of purifying the soul, and preparing it for eternal life.

According to the doctrine of the old Egyptians, the human race originated after the pure gods and spirits had left the earth; and this they did because the demons, who inhabited the earth, had revolted against them, and therefore tainted it with guilt. But, in order to enable the demons to purge themselves of their guilt, the gods created earthly bodies, which the demons were sentenced to animate, so that by expiations they might regain their state of original purity. And these earthly bodies, united to the demons, are the human race; their souls were therefore created at the same time as that of the gods; and human life—the connection of body and soul—is merely intended as a means of purifying the soul, which had rebelled against its divine nature. All the precepts regulating the course of life are laid down by the Egyptians for this end; and the judgment passed after death, in the palace of Osiris, decides whether it has been attained or not. If it has not, the soul must return to the earth again, to renew its expiations; and according to the nature and measure of the guilt which it had contracted during its previous career, it must form a new union with a human body, or with the body of an animal or even a plant. But if the soul is declared pure by the judge of the dead, it gradually ascends through the various regions of heaven, to the highest abodes of the gods and pure spirits, presided over by Phtah and Neith.

At the time when in *India* the dogma of transmigration became an integral part of the Brahmanic religion, the Hindus believed that the human souls emanated from a supreme Being, which, as it were, in a state of bewilderment or forgetfulness, allowed them to become separate existences, and to be born on earth. The soul, thus severed from the real source of its life, is bound to return to it, or to become merged again into that divine substance with which

it was originally one, but as its nature becomes contaminated with sin through its earthly career, it must, so long as it remains in this world, endeavour to free itself from all guilt, and thus to become fit for its ultimate destiny. Religion teaches that this is done by the observance of religious rites, and a life in conformity with the precepts of the sacred books; philosophy, that the soul will be re-united with Brahman, if it *understands* the true nature of the divine essence whence it comes. So long, therefore, as the soul has not attained this condition of purity, it must be born again, after the dissolution of the body to which it was allied; and the degree of its impurity at one of these various deaths, determines the existence which it will assume in a subsequent life. See INDIA, sec. *Religion and Philosophy*; and UPANISHAD.

Since there can be no proof of the soul's migrations, the detail in which these are described in the religious works of the Hindus, is merely fantastical, and interesting only so far as it affords a kind of standard by which, at various epochs, and by different writers, the moral merit or demerit of human actions was measured in India. Thus, Manu (in the 12th book of his Code of Laws) teaches: 'The slayer of a Brâhman'a—according to the degree of his guilt—is reborn as a dog, a boar, an ass, a camel, a bull, a goat, a sheep, a stag, a bird, a Chân'dâla, or a Pukkas'a. A Brâhman'a, who drinks spirituous liquor, will migrate into the bodies of a worm, an insect, a grasshopper, a fly feeding on ordure, or some mischievous animal. A twice-born who steals (the gold of a Brâhman'a), will pass a thousand times into the bodies of spiders, snakes, and chameleons, of aquatic monsters, or of murderous bloodthirsty demons. He who violates the bed of his guru, will a hundred times migrate into the forms of grasses, of shrubs, and of creeping plants, of carnivorous animals and beasts with long teeth, or of cruel brutes. Those who inflict injury (on sentient beings), become flesh-eaters; and those who eat forbidden things, worms. Thieves become devourers of each other; and those who embrace women of the lowest castes, become ghosts. . . . . If a man, through covetousness, has stolen gems, pearl, or coral, or whatever belongs to the precious substances, he is reborn in the tribe of goldsmiths; if he has stolen grain, he becomes a rat; if kânsya (a composition of zinc and copper), a *hansa* bird; if water, a diver; if honey, a gadfly; if milk, a crow; if juice (of the sugar-cane or the like), a dog; if clarified butter, an ichneumon; if flesh, a vulture; if fat, a shag; if oil, a cockroach; if salt, a cricket; if curds, the crane, called Valâkâ;' &c. A more general doctrine of the migration of souls is based by Hindu philosophers on the assumption of the three cosmic qualities of *sattwa*, i.e., purity or goodness; *rajas*, i.e., troubledness or passion; and *tamas*, i.e., darkness or sin, with which the human soul may become endued. And on this doctrine, again, Manu and other writers build an elaborate theory of the various births to which the soul may become subject. Manu, for instance, teaches that 'souls endued with the quality of *sattwa*, attain the condition of deities; those having the quality of *rajas*, the condition of men; and those having the quality of *tamas*, the condition of beasts.' Each of these conditions, he continues, is, according to the acts or knowledge of the soul, threefold: the lowest, the middle, and the highest. 'The lowest embodiment of the quality *tamas* is inanimate objects, worms, insects, fish, serpents, tortoises, tame and wild beasts; the middle state, to which the same quality leads, is (the state of) an elephant, a horse, a S'ûdra, a Mlechchha or barbarian, a lion, a tiger, and a boar; the highest, that of a public performer, a bird, a cheat, a demon called Rakshas, and a vampire-demon. The lowest condition to which the soul imbued with the quality *rajas* arrives is that of a cudgel-player, a boxer, a public dancer, a man who lives on the use of weapons, and one addicted to gambling and drinking; the middle condition, that of a king, a man of the Kshattriya or military caste, a house-priest of a king, and a man fond of learned controversy; the highest, that of a Gandharva or musician in Indra's heaven, a Guhyaka or Yaksha (two kinds of attendants on the god of riches), or another attendant on another god, or a Apsaras or heavenly nymph in Indra's heaven. The lowest state procured by the quality of *sattwa* is that of a Vânaprastha—or a hermit of the third order of life—a religious mendicant, a Brâhman'a, or one of the demigods travelling about in palace-like cars, one of (the genii presiding over) the lunar mansions, or an offspring of Diti. The middle state, procured by the same quality, is that of a sacrificer, a Rishi (q. v.), a god of the lower heaven (a deity personating one of the) Vedas, (a deity presiding over one of) the luminaries or years, one of the manes or progenitors of mankind, and of the demigods called Sâdhya. The highest condition to which the quality of *sattwa* leads is that of the god Brahmâ, that of a creator of the world (as *Marîchi*, or another patriarch of the same rank), that of the genius of Dharma (virtue or right), of *Mahat*, or the intellectual principle of creation, and of *Prakr'iti*, or matter.' See SANKHYA.

It is not necessary here to shew that this detail regarding the migrations of the souls is more or less differently given by other authors at other periods of Hindu religion, according to the views which they entertained of right and wrong, of the value and rank of imaginary or created beings, and of the social conditions of men. For, since all orthodox Hindu writers agree in principle with Manu, the quotations alleged from his work suffice to illustrate the imaginary positiveness with which the doctrine of transmigration was propounded, and to establish the conclusion that this doctrine rested in India on ethical grounds.

It has been already pointed out that the belief in the soul's life after the death of the body must precede the doctrine of transmigration. As such a belief, however, may be traced in some hymns of the *R'igveda* (see VEDA), it has been supposed that this doctrine, too, is as old as this Veda. But apart from the uncertainty which still exists regarding not only the age, but even the relative age at which the different hymns of the *R'igveda* were composed, and setting aside the fallacy which therefore attaches to speaking of this Veda as a contemporaneous whole, it is necessary to observe that the only passage which has been adduced in proof of this important discovery does not bear it out. It is the 32d verse of the hymn I. 164, and, according to the translation of Professor Wilson (vol. ii. pp. 137, 138), runs as follows: 'He who has made (this state of things) does not comprehend it: he who has beheld it, has it also verily hidden (from him); he, whilst yet enveloped in his mother's womb, is *subject to many births*, and has entered upon evil.' But the word of the text, *bahuprajâh'*, rendered by Wilson, according to the commentator, 'is subject to many births,' may, according to the same commentator, also mean, 'has many offsprings,' or 'has many children;' and as the latter sense is the more literal and usual sense of the word, whereas the former is artificial, no conclusion whatever regarding the doctrine of transmigration can safely be founded on it.

The Buddhistic belief in transmigration is derived from that of the Brahmanic Hindus; it agrees with

the latter in principle, though it differs from it in the imaginary detail in which it was worked out.

Like the Brahmanic Hindus, the Buddhists believe that all souls have existed from the beginning; like them, they believe in the unreality and sinfulness of the world, in the necessity of the soul's freeing itself from the bondage of this world, and in the casual connection between the actions of man in this, and his conditions in a subsequent life. Like the Brahmanic Hindus, they hold, therefore, that sin is the cause of transmigration, and that by a total expiation of sin, the soul ceases to be reborn, and attains its final resting-place. But since this resting-place is to the Buddhists Nirvâna (q. v.), or Non-entity, whereas to Brahmanism it is Brahman, or the principle of Entity; since they reject the institution of caste, which is the social foundation of Brahmanic life; since they do not acknowledge the authority of the Vedas, and the codes based on it, and therefore consider as morally wrong much that the Brahmanic 'Sâstras enjoin as morally right, the standard according to which the life of a Buddhist is regulated must differ in many respects from that which governs the conduct of a Brahmanic Hindu; and his ideas of reward and punishment, therefore, as reflected by his ideas of the mode of transmigration, likewise differ from those of the Brahmanic believer. To enlarge here on this difference is not necessary, for, after the illustrations already afforded from Manu, it is easy to conceive that the *detail* of the Buddhistic doctrine of transmigration is as fanciful as that of the Brahmanic doctrine; that it is therefore partly devoid of interest, and partly intelligible only if taken in connection with the detail of Buddhistic religion and literature (see BUDDHISM; also LAMAISM). Yet it is not superfluous to point out one great difference which separates the notions of one class of Buddhists from those of the rest, as well as from those of the Brahmanic Hindus. According to the latter, and the great mass of Buddhists, it is always the same soul which ever from its first birth reappears in its subsequent births, until it is finally liberated from transmigration. But among the southern Buddhists, another idea has also taken root. In their belief, the succession of existences of a being is also a succession of souls; and each such soul, though the result of its predecessor, is not identical with it. According to this view, the body dies, and with it the soul, too, is 'extinguished,' leaving behind only the good and bad acts which it has performed during its life. The result of these acts now becomes the seed of a new life, and the soul of this new life is therefore the necessary product of the soul of the former life. Thus all the succeeding souls have to labour at the solution of the same problem, which began when their first ancestor entered this world, but no succeeding birth is animated by the same soul. This dogma is illustrated in their works by various similes. One lamp, they say, for instance, is kindled at another; the light of the former is not identical with that of the latter, but nevertheless, without this, the other light could not have originated. Or, a tree produces fruit; from the fruit, another tree arises, and so on; the last tree is therefore not the same as the first, though the fruit is the necessary cause of the last.

In Greece, the doctrine of transmigration—or, as it is there called, *metempsychosis*—did not become the belief of the people, but was confined to the teaching of the mysteries and the tenets of philosophers, who probably derived it, either directly or indirectly, from Egypt or India. According to some, Thales (q. v.) was the first Greek philosopher who propounded it; according to others, Pherecydes (q. v.), the teacher of Pythagoras (q. v.); but its importance in Greek philosophy it first obtained through the system of Pythagoras, who, it seems, became acquainted with it through Egyptian sources. After him, it was Plato (q. v.) who assigned to it a prominent place in his philosophy; and he probably was indebted to Hindu writers for his views on metempsychosis, as explained in his dialogues, especially in *Phædros*. Plato's doctrine was refuted by Aristotle, but revived, though in a modified shape, by the Neo-Platonists.

Since a belief that the consequences of the acts of man must follow their inevitable course, and can neither be averted nor stopped by the intercession of a divine power, is incompatible with a belief in divine grace, the doctrine of transmigration or metempsychosis could never gain a firm ground in the religion of the Jews and Christians. It deserves notice, however, that in both these religions it found adherents as well in ancient as modern times. Amongst the Jews, the doctrine of transmigration—the *Gilgul Neshamoth*—was taught in the mystical system of the *Kabbala*, which pretends to divulge the secrets of creation and those of the nature of the divine and human soul. 'All the souls,' the *Sohar*, or the book of 'light,' the spiritual code of this system, says, 'are subject to the trials of transmigration; and men do not know which are the ways of the Most High in their regard. They do not know how they are judged in all times, as well before they come to this world as after they leave it. They do not know how many transformations and mysterious trials they must undergo: how many souls and spirits come to this world without returning to the palace of the divine king.' The principle, in short, of the Kabbala is the same as that of Brahmanism. The souls, like all other existences of this world, it teaches, must re-enter the absolute substance whence they have emerged. But to accomplish this end, they must develop all the perfections the germ of which is planted in them; and if they have not fulfilled this condition during one life, they must commence another, a third, and so forth, until they have acquired the condition which fits them for their re-union with God. On the ground of this doctrine, which was shared in by Rabbis of the highest renown, it was held, for instance, that the soul of Adam migrated into David, and will come into the Messiah; that the soul of Japhet is the same as that of Simeon, and the soul of Teran migrated into Job. Generally, it was supposed by writers of this school, the souls of men are reborn in men, and those of women in women; but also the reverse takes place, as in the case of Thamar, who had the soul of a man, and in that of Judah, whose soul was in part that of a woman. And because Ruth had the soul of Thamar, she could not bear children until God imparted to her sparks of a female soul. If the soul of a man, however, is reborn in a woman, such a migration is held by some to be a punishment for the committal of great sins, as when a man refuses to give alms, or to communicate to others his wisdom. And it is by way of punishment, too, that the soul of a Jew is reborn in a heathen, or in an animal—a clean or unclean beast, a bird, a fish—or even in an inanimate object. Of all these transmigrations, biblical instances are adduced—according to their mode of interpretation—in the writings of Rabbi Manasse ben Israel, Rabbi Naphtali, Rabbi Meyer ben Gabbai, Rabbi Ruben, in the Jalkut Khadash, and other works of a similar character. Modern Kabbalists—for instance, Isaac Loria—have imagined that divine grace sometimes assists a soul in

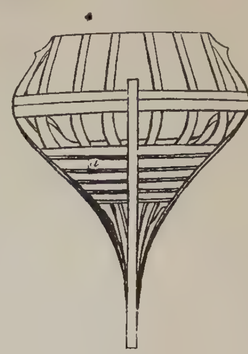
its career of expiation by allowing it to occupy the same body together with another soul, when both are to supplement each other, like the blind and the lame. Sometimes only one of these two souls requires a supplement of virtue, which it obtains from the other soul, better provided than its partner. The latter soul then becomes, as it were, the mother of the other soul, and bears it under her heart like a pregnant woman. Hence the name of gestation or impregnation is given to this strange association of two souls. That all these wild fancies have for their main object the explanation of obscure or mystical passages of the Bible, and the reconciliation of such as are or may seem contradictory, requires no remark; the philosopher, however, must look to their basis, which is purely ethical.

Among the early Christians, St Jerome relates the doctrine of transmigration was taught as a traditional and esoteric one, which was only communicated to a selected few; and Origenes, like the Kabbalists, considers it as the only means of explaining some biblical traditions, as that of the struggle of Jacob and Esau before their birth, or the selection of Jeremiah when he was not yet born, and many more events which would throw discredit on divine justice, unless they were justified by good or bad acts done in a former life. Of Christian sects, the Manichæans (q. v.) especially adhered to this belief, but the church always rejected it as a heresy.

In concluding, at least one great philosopher of modern times may here be named, as one whose views of the progress of mankind are based on the same doctrine; it is the celebrated German critic, G. E. Lessing, who endeavoured to establish it on metaphysical grounds. His arguments are briefly these: The soul is a simple being, capable of infinite conceptions. But being a finite being, it is not capable of such infinite conceptions at the same time; it must obtain them gradually in an infinite succession of time. If, however, it obtain them gradually, there must be an order in which, and a degree to which, these conceptions are acquired. This order and this measure are the senses. At present, the soul has of such senses five; but neither is there any ground to assume that it has commenced with having five senses, nor that it will stop there. For, since nature never takes a leap, the soul must have gone through all the lower stages before it arrived at that which it occupies now . . . . and since nature contains many substances and powers which are not accessible to those senses with which it is now endued, it must be assumed that there will be future stages, at which the soul will have as many senses as correspond with the powers of nature. And 'this my system,' he concludes his little but important essay, *Dass mehr als fünf Sinne für den Menschen sein können*—in a fragmentary note discovered after his death—'this my system is certainly the oldest of all philosophical systems; for it is in reality no other than the system of the pre-existence of the soul and metempsychosis, which did not only occupy the speculation of Pythagoras and Plato, but also before them of Egyptians, Chaldeans, and Persians—in short, of all the sages of the East; and this circumstance alone ought to work a good prejudice in its favour; for the first and oldest opinion is, in matters of speculation, always the most probable, because common sense immediately hit upon it.'

TRA'NSOM, a horizontal mullion or bar in a window, door, &c., chiefly used in late Gothic and Elizabethan architecture.

TRANSOMS, in Artillery, the bars or bolts by which the two sides—technically called 'cheeks'—of a gun-carriage are held together.—In a Ship, beams across the sternpost, at right angles to that timber



a, Transom.

fastened in the same way as the floors upon the keel.

TRA'NSPADANE REPUBLIC. See CISALPINE REPUBLIC.

TRANSPLA'NTING—the removal of a growing plant from one situation to another—is much practised with many kinds of cultivated plants, which are reared in a nursery, and *planted out*. Many flowers and culinary plants are generally treated in this way, as well as ornamental shrubs, and fruit and forest trees. It is desirable to have a ball of earth attached to the roots in every case, although this is often neglected. It is also desirable to shade the plant and water it for a few days after transplanting, when possible. Young plants are easily transplanted, as their roots, not having spread far, are raised from the ground without much injury, and this is the thing of first importance in the operation. At a more advanced age, transplanting becomes difficult, great part of the difficulty, however, being mechanical. No plant can be transplanted with safety when in flower or fruit; the plant may live, but the flowers or fruit will almost certainly perish. In like manner, leaves often wither; and transplanting ought, if possible, to be performed in winter, when vegetation is least active.

The transplanting of large trees, in order to immediate effect in the neighbourhood of a mansion, has been practised for many years with success. Notwithstanding all the care that can be taken, the trees are *thrown back* for two or three years; but this, in general, is all the injury which they sustain, unless removed from a situation very different from that in which they are placed. It is of great importance, in transplanting trees, that they should be placed in their new situation in the same direction to the prevailing wind as in their former situation. This is often disregarded, and many failures are the consequence. It ought also to be borne in mind, that trees taken from a thick wood, and planted in a lawn, or along the sides of an avenue, cannot be expected to succeed there. They have neither roots nor branches adapted to their new situation, and suffer from unaccustomed exposure to wind and weather. Trees of quick growth, such as limes and poplars, succeed most readily when transplanted; oaks are particularly difficult. In every case, however, there is much hazard, because the roots of trees generally spread far from the stem, and when the operation is unskilfully performed, the principal roots are often cut off, and the

smaller ones torn by the violence used, whilst all are injured by being laid bare. Trees thus treated seldom ever again assume a healthy appearance. The method is therefore now generally adopted of preparing the tree for transplanting by digging a trench around it, at least two years beforehand, at such distance as is thought expedient, cutting the roots all round, except two or three which are left to hold the tree fast, and then filling up the trench with fresh soil of the best quality that can be procured, into which a vast number of young roots are speedily thrown out. When the tree is to be removed, a new trench is made immediately on the outside of the former trench, and young roots sufficient for the nourishment of the tree are thus preserved. The ball of earth being generally too heavy for removal, is reduced in size by a very careful picking away of earth, so that the rootlets shall be as little as possible injured or even laid bare. The tree is generally transported to its new situation by attaching it firmly to a pole fixed upon an axle with a pair of wheels, the ball resting upon the axle. Good soil is put into the pit dug for it, and the roots are spread out. The tree is stayed by sticks and ropes till it is well established, and heavy stones are also laid on the top of the ball, or large beams of wood are laid across it, and firmly fastened to the ground at both ends. An improvement on this method has been effected by the use of a compost of vegetable mould, decayed leaves, &c. in preparing the tree for transplanting, not only in the trench dug around it, but on the top of the ball itself, so that the tree is encouraged to send out many new rootlets. A still greater improvement consists in the use of a machine by which a large ball of earth can be removed along with the tree, so that it is no longer necessary to pick away any part of the soil or to lay bare the young roots; whilst the tree being carried in a vertical instead of a horizontal position, all possibility of damage in this process is avoided. The machine used for this purpose consists of two pair of wheels, about 15 feet apart, each pair on a strong axle; the first pair smallest, and in a very large machine about 5½ feet in diameter; the second pair 7 feet. A strong frame rests on each axle to raise the horizontal bearers to a sufficient height. The front frame turns on a horizontal wheel, as in a carriage, for easy turning of the whole machine. Resting on the two frames are two strong horizontal beams of wood, above which are two short cross beams, with jack screws and strong chains for raising the tree. Beneath the roots and ball of earth, when the tree is raised from the ground, strong planks are placed, supported by chains from the beams. In order to raise the tree from its place, a sloped cutting is made, and the tree is drawn gradually up the inclined plane.

Transplanting Apparatus.

TRA'NSPORT, MILITARY AND NAVAL. Without a powerful system of transport, an army is helpless. To cross a sea, a large fleet of vessels properly fitted for men and horses, is requisite. When the English army, of about 30,000 men, crossed, in 1854, from Varna to the Crimea, it took 600 vessels to carry them, without any reserves of stores or food.

Not less important to the army moving by land is its transport. On entering battle, infantry and cavalry usually carry three days' rations with them, and 60 rounds of ammunition. The moment these are exhausted, they become dependent on the transport department for their replenishment. The first reserves are immediately in rear. To bring up supplies from these, and to keep these reserves themselves supplied, is the duty of the Military Train (q. v.) as regards food, and of the field-train in respect of ammunition. Between the grand dépôt and the base, the operation is generally intrusted to the wagons and beasts of the country, driven by natives, of course under proper military control. The amount of transport required by an army seems almost fabulous. The lowest computation must put one animal to four fighting-men. In addition to the transport of food and ammunition, the wounded and sick have to be carried, both from the field to the hospitals and during a march.

In the British army, the direction of the transport rests with the quartermaster-general: in the French army, it is under the *Intendant*, who is over all the administrative departments.

TRANSPORTA'TION, from the Latin for carrying across, means the removing of persons from one territory to another; and is thus distinguished from banishment, which is the mere driving of persons out of the country in which they live. Transportation, in this country, means a removal beyond seas, and has been in use to express the punishment of crime in that manner. The practice was known to the Romans; and transportation to Sicily will be found referred to in Cicero's charges against Verres. When the English monarchs had possessions on the continent, there was much jealousy about their carrying off troublesome persons to these dominions, and thus bringing them under irresponsible power. The legal transportation of criminals from the British dominions began early in the 17th c., when they were removed to the Plantations in America, and treated as slaves. This practice continued, under modifications, until it was stopped by the American revolution. Its unfitness as a punishment is obvious. The amount of infliction would depend, not on the extent of the criminal's guilt, but of his master's humanity. There were even worse evils; for young lads were kidnapped in Britain, and sold to the planters, and these victims were often unable to prove, even when they had an opportunity, that they were not legally transported for offences. When this method of getting rid of convicts ceased, there was great alarm that Britain would be overrun with crime, and it was hailed as a deliverance when the government resolved to establish a penal colony in Australia. The first convicts were conveyed thither in 1787. Such was the beginning of the famous colony of Sydney, or Botany Bay. Between the years 1820 and 1830, the system was at its full perfection; but though thousands were annually removed, crime did not appear to decrease. It was forgotten, that the predatory and fraudulent offences, which are by far the greater number in this country, are trade as well as crime; and that where there is a large

portion of the population, as there unfortunately is, prepared to have recourse to crime whenever it pays, the place of those removed is immediately supplied. When the criminals were sent to the antipodes, the mistake was made of supposing that they took the crime of the country with them, and that there was so much less need for precautionary measures at home. During twenty years, however, the greater proportion of the class of criminals who used to be transported, have been retained in this country, and liberated in it at the end of their punishment. This practice has been accompanied with two classes of precautionary measures—an improved police, and the reformation of juvenile delinquents. To these influences have been added free trade, and the consequence of all is, that crime is diminished to the extent of between a third and a half of what it was 20 years ago. In 1838, a committee of the House of Commons issued a celebrated Report on the effect of transportation. It was shewn to be still an extremely unequal punishment—in some instances giving rogues an opportunity of making their fortune, in other cases subjecting men less depraved, but more infirm in temper, to punishments of the most frightful kind. It was found to be accompanied by the prevalence of crimes which cannot be mentioned, and with a vast amount of general demoralisation in the convict settlements. Yet it was found not to have much terror for the criminal classes, who heard more about the success than the hardships of transportees. In 1840, transportation to New South Wales came to an end; and by a succession of statutes, sentences to penal servitude were substituted for sentences to transportation. Penal serfs can be transported, and a small colony of them is still continued in Western Australia. The practice of transportation cannot, it will be easily understood, be carried out by governments which have no colonies, though Russia manages it by possession of the desolate region of Siberia. It is a curious circumstance that the practice began in France just as Great Britain was abandoning it.—See CONVICT, PENAL SERVITUDE, PRISON DISCIPLINE, TICKET OF LEAVE.

TRANSPO'SE, in Music, is to change a piece of music in performance from the key in which it is written to another key. To play at sight an accompaniment for such an instrument as the pianoforte or organ, transposed from one key to another, requires considerable artistic skill. To the singer, transposal presents no difficulties.

TRANSUBSTANTIA'TION (Lat. *transubstantiatio*, change of substance, from *trans*, over, and *substantia*, a substance), a word used by the scholastic writers of the Roman Catholic Church to designate the change which is believed by Roman Catholics to take place in the Eucharistic elements of bread and wine, in virtue of the consecration. Under the head REAL PRESENCE (q. v.), which is often loosely comprehended under the larger name of transubstantiation, the doctrine of Catholics as to the presence of the body and blood of Christ in the Eucharist, after consecration, has been fully explained. There remains, however, beyond this doctrine as to the presence of Christ, a further inquiry concerning the elements of bread and wine which had existed in their natural condition before the consecration. For Sacramentarians (q. v.), this question is easily resolved. But those Protestants who hold in common with Catholics the reality of Christ's presence, differ from them as to the co-presence of the substance of bread and wine after consecration. Some Anglican divines, who hold the real presence of the body and blood, would appear to content themselves with remaining silent as to the mode of the presence. Dr Pusey goes so far as to say, that the dispute between Anglicans and Romanists is 'probably a dispute about words' (*Eirenicon*, p. 229). The Lutheran views as to the mode of the presence have been explained under the heads IMPANATION, REAL PRESENCE (q. v.). According to the Catholic doctrine, which has been explicitly defined as an article of faith (Council of Trent, Sess. xiii. Can. 2), 'the whole substance of the bread is changed into the body of Christ, and the whole substance of the wine into His blood, the species alone remaining.' What is the precise philosophical meaning of the word 'species,' called also 'accidents,' in this definition, is not declared; but in popular language it may be described as simply meaning the appearances, that is to say, those qualities or conditions of bread and wine which produce upon the senses the impression of the presence of bread and wine. It is not taught, however, that in the change called transubstantiation, the body and blood of Christ are formed out of the substance of the bread and wine, but that, in virtue of the Eucharistic consecration, the substance of bread and wine cease to exist, and that the body and blood of Christ take their place; nor that the body and blood of Christ become what the schoolmen call the 'subject' of the 'accidents' of the bread and wine, but merely that, by a miraculous suspension of the ordinary law, the senses still continue to receive from the Eucharistic elements all the same impressions which they had previously received from the bread and wine; viz., of colour, taste, smell, solidity, extension, figure, &c.

The history of the controversy regarding transubstantiation is sketched in the article LORD'S SUPPER. The objections to the doctrine have been chiefly drawn from the philosophical difficulties which are involved in it; and the defenders of it have, for the most part, contented themselves with resting on the proofs which they profess to draw from Scripture and tradition, and a general demonstration that the doctrine, although mysterious, does not involve any philosophical repugnance or impossibility, and that the philosophical arguments against it are at the least not conclusive. Some Catholic philosophers have even undertaken to demonstrate the possibility of transubstantiation by philosophical arguments; and it is especially remarkable that the celebrated Leibnitz (q. v.) has not only entered at great length, and in several portions of his works, into this philosophical discussion, but professes to prove, by strict philosophical principles—by the consideration of the properties of matter, of substance, of space, extension, and the like—that the essential principle of the body 'may exist in many places at the same time, nay, under far-distant and distinct species.'—Leibnitz's *Deutsche Schriften*, i. pp. 283, 284.

TRANSVAAL (*i. e.* 'across the Vaal'), until 1877 a republic of South Africa, but now a part of Cape Colony, includes the country north of the Vaal River, and on both slopes of the Cashan Mountains, into which the emigrant Boers retired after the annexation of the Orange River Free State, in 1848, to the British crown, and declared their independence in 1852. Its limits lie between lat. 22°—27° S. and long. 27°—31° E. The N. boundary is formed by the Oori or Limpopo River, here running nearly from west to east; its E. boundary by the continuation of the Drachenberg Mountains, separating it from the coast-region, inhabited by the Zulu Kaffirs; on the S., it has the Vaal River from its source, dividing it from the Free State Republic; while on the W., an undefined line separates it from the Betjuana tribes, still independent, living along the edge of the desert

region of the Kalihari. Thus, an area of not less than 70,000 sq. m. is more or less under the control of the emigrant Boers, who are not very scrupulous in their dealings with the poor native tribes who lived, or live still, in the country they now occupy. This region may be described in general terms as a vast plateau, sloping to the north, supported by the coast-line of mountains, which, presenting a bold mural buttress, or escarpment, to the low country at their feet, stretch away on their western flank into vast undulating plains. At right angles to the coast-range, another belt of very high lands, called the Magaliesberg, runs east and west forming a watershed between the river-system of the Vaal or Orange and Limpopo rivers. The southern face of this range also presents long and undulating plains, generally well watered and wooded, and abounding with large game. To the north, as we approach the basin of the Limpopo, many high parallel chains of hills are met with, through narrow *poorts* or openings in which flow the many streams which form, further to the north-west, the Limpopo or Oori River, which is supposed to enter the ocean as the Sabia, in lat. 20° 43′ S., long. 34° 30′ E. This point, however, is still one in dispute with African geographers. See SOFALA. The rivers of the Transvaal region are more generally applicable for irrigating purposes than those of the Free State or Cape Colony in general, their channels not lying so deep below the general surface of the country.

The average height of the plateau inhabited by the emigrant farmers of European descent is from 4000 to 5000 feet. Many of the peaks of the mountain-range traversing the plateau attain an elevation of 9000 or 10,000 feet, and are covered with snow some months in the year. The altitude of the coast-line of mountains is considered at from 6000 to 7000 feet above the low region at their feet.

The principal towns are—Mooiriverdorp, or Potscherfstroem, favourably situated on the Mooi River, about 20 miles north of the Vaal River, the seat of the local government; Rustenberg, a few miles north of the Magaliesberg and Zoutpansberg, the most remote village inhabited by men of European descent in South Africa, about 40 miles south of the Limpopo River.

The population consists of emigrant farmers, and a mixture of deserters and foreign refugees from the Cape Colony and Natal. Their number, as far as can be ascertained, is about 30.000 souls. Scattered through the country are numerous kraals of Betjuans, who live in a kind of servitude, if not actual slavery, amongst their white masters, to whom they have to supply labour whenever required. Education is at a very low ebb, and the majority of the Boers are prejudiced and narrow-minded to a lamentable degree; and to the want of proper educational and religious advantages must be attributed their treatment of Livingstone, and many other European missionaries and travellers in those regions; but they still preserve a strong religious feeling of a high Calvinistic tendency, and although otherwise illiterate, there are but few Boers who cannot read their Bible and hymn-book.

The system of government is republican, and resembles that of the Orange River Free State (q. v.). The president is elected by the people, and holds office for five years. The government is administered by two bodies—the executive council, of which the president is chairman, and the legislative council, which consists of three members, chosen from each of the twelve districts into which the country is divided. In 1873 the public debt was £60,000. The budget for the year ending 31st January, 1874, gives the revenue at £49,318, and the expenditure at £45,481.

The climate is generally healthy, although north of the Magaliesberg its tropical nature begins to manifest itself. Hot winds and violent thunderstorms prevail in the summer months. The fly *Tsetse*, whose bite is death to the bovine and equine species, abounds in many parts, and renders travelling with oxen and horses difficult. A considerable trade is carried on with Natal; and parties of Boers occasionally, in the winter season, venture as far as the Portuguese factories at Sofala, Inhambane, and Delagoa Bay, to barter ivory and bees-wax, sawn timber, &c., for gunpowder, lead, coffee, &c.

When Captain Harris visited this region about 1835, the number of the larger mammalia found by him was enormous; and even Gordon Cumming, who hunted over part of it many years subsequently, found them still numerous. But the elephant, rhinoceros, and giraffe have been of late years slowly receding into the densely-wooded country near the sea-coast; and the larger antelopes are fast migrating into the Kalihari and country to the north-west. Crocodiles are numerous in the rivers, and a large species of boa is found. The geology appears to present the same features as in a large portion of the Cape Colony and Natal, table-topped mountains, and the peculiarly sharp peaked hills called Spitzkoppen are numerous. In May 1870 the Vaal valley was the scene of great activity, thousands being attracted thereto by the extraordinary diamond-fields discovered on the banks of the Vaal.

Mooiriverdorp is by land 960 miles north-east of Cape Town, and Zoutpansberg is 1300, and about 250 miles north-west of Delagoa Bay.

TRANSYLVA'NIA (called by the Hungarians *Erdély-Orszag*—Walach, *Arjal*—'the woody and mountainous country;' by the Germans *Siebenbürgen*, 'seven castles,' from the seven forts built by the Saxons on their establishment in the country, and which forts became nuclei of the walled cities of Hermannstadt, Klausenburg, Kronstadt, Bistritz, Mediasch, Mühlenbach, and Schäsburg and by the Romans *Transylvania*, from its position *beyond* the forest range which stretches southwards from the Carpathians, and forms its western boundary) is the most easterly crownland of Austria, and is bounded on the N. by Hungary and Galicia, E. by Bukovina and Moldavia, S. by Wallachia, and W. by the Military Frontier, the Banat, and Hungary. It contains 21,107 Eng. sq. m., with a pop. (1869) of 2,109,107, of whom 1,200,400 were Wallachs and Eastern Roumains, 573,000 Magyars and Szeklers, 235,000 Germans, the rest being Sclaves, gipsies, Armenians, Jews, Italians, &c. Classed according to their religious professions, in 1857, 623,055 were Non-united Greeks, 551,994 Greek-Catholics and Armenians, 461,837 Protestants, 228,095 Roman Catholics, and 14,152 Jews. T. is an elevated plateau (its lowest parts being 530 feet above sea-level) of an irregular form, somewhat resembling a triangle of which the upper part has been irregularly removed, and is bounded partially on the north, and wholly on the east and south, by a high range of mountains—a continuation of the Carpathians—which sends out innumerable lateral ridges towards the centre of the country, and along the western frontier, so that T. is an almost perfect natural fortress. There are no plains except where a river-basin widens out; but the valleys are numerous and exceedingly picturesque. Almost the whole country is drained westwards into the Danube, by the Theiss and its feeders in the north, and by the Maros, a tributary of the Theiss, and its feeders, in the centre and south; the south-eastern corner is drained by the Aluta, or Alt, which, after a winding course, breaks through the southern bounding range near Hermannstadt; while a number of streamlets

worm their way through the eastern range, and join the Sereth. The climate is more healthy and temperate than that of Hungary, the mountain-chain along the southern frontier keeping off the hot winds. The soil is extremely fertile; but much arable land is still uncultivated. The valleys and hill-sides supply abundant pasturage for numerous herds of cattle and droves of horses; the cultivated districts yield good crops of maize, rye, barley, oats, all sorts of leguminous plants, tobacco, saffron, madder, hemp, and lint. The culture of fruits is extensively practised, and immense quantities of apricots, peaches, plums, apples, pears, and walnuts, are annually produced. The extensive forests, which cover nearly 5,300,000 acres of ground, contribute largely to the wealth of the country. The vine is extensively cultivated, and, in spite of the defective mode of preparation, the produce is excellent in quality. The mineral wealth of T. is great; gold is found more abundantly than silver, and silver than copper; yet there are few gold mines regularly worked, and a thorough investigation of the extent to which this valuable metal exists in the country, seems never to have been made. Iron is found in abundance at Torockzo, copper at Balan, lead at Rodna; the other minerals are mercury, manganese, antimony, sulphur, arsenic, vitriol, alum, marble, &c. Coal is not absent; but firewood is so abundant and cheap, that no other combustible has been sought for; and even the extensive tracts of peat have been allowed to lie undisturbed. Rock-salt is abundant. T. has almost no manufactures, and the commerce, owing to the isolation of the country, the want of enterprise of its inhabitants, and the absence of good roads, is far from bearing a fair proportion to the amount of the country's produce.

Of the various races which now inhabit T., the Wallachs, the earliest possessors, though by far most numerous, were till recently subordinated to the other races of T., but since the revolution of 1848—1849, have acquired a position in the country which, by all means, honest or dishonest, they are striving to improve; the Magyars entered as conquerors in the 10th c., and still constitute the nobility and gentry of the land; the Saxons were introduced in 1143 and 1247 from the Rhenish provinces of Lower Saxony, by Kings Geysa II. and Bela IV. of Hungary, and received special privileges and immunities to induce them to settle in the country, and improve the cultivation of the soil; and the Szeklers, or Szekhelyi, are believed to be the descendants of the once formidable Huns. The last three are the dominant races of T., and live apart from each other—the Magyars occupying the west and centre, the Saxons the south and north-east, and the Szeklers the south-east. The Magyars, Bulgarians, and Armenians speak the Magyar language as used in Hungary; the Saxons employ Low-German in speaking, and High-German in writing, but with a considerable mixture of Magyar in both; the Szeklers speak a Turanian dialect; and the Wallachs use their own language intermixed with corrupt Latin. T. is little noticed in history till the Christian era, when part of it was occupied by the warlike Dacians, soon after whom the Sarmatian tribes of the Jazyges and Carpi settled in it. The conquest of the Dacians by Trajan, however, did not include that of the other two peoples, who proved very troublesome to the Roman settlers along the Danube, till they were conquered by Diocletian, and the Carpi carried away to Pannonia and other districts. In the middle of the 4th c., the Goths overran the country, defeating the Sarmatians in a great battle on the Maros, in which the monarch and the chief of his nobility perished; and they in their turn were forced, in 375, to retire before the Huns and their confederates. The Gepidæ next took possession of T. till their almost complete extirpation, in 566, by the Lombards and Avars. It was conquered by the Hungarians about 1000, and was governed by Woivodes till 1526, when the death of the Hungarian monarch at Mohacs prepared the way for the union of the two countries under the Woivode, John Zapolya; but the war which thence arose with the Austrians caused their complete severance, and Zapolya's sway was, in 1535, confined to T., of which he became sovereign lord, under the protection of the Turks. T., on its conquest by the Hungarians, was only partially settled; the eastern part constituted a grazing-ground for wandering tribes who had migrated thither. The Saxons were summoned by the Hungarian monarchs to act as a counterpoise to the increasing power of the nobles; and from similar motives the Burzen land was given to the Teutonic Knights, but the arrogant bearing of those soldiers of the cross soon offended their titular lord, and they were forced to leave the country. The 'golden charter' of King Andrew II. (1224) secured a perfectly free political system to the Saxons, whose 'comes' or chief was, like the head of a clan, both judge and leader, and from whom the only appeal was to the king in person. The firm protection and generous treatment accorded to the Saxons by the Hungarian monarchs were rewarded by steadfast loyalty, and succour in men and money whenever required. During the rest of the 16th c., the country was distracted by the bitter strife between the Catholic party, who were supported by Austria, and the Protestant party, who were allied with the Turks; the latter party, headed successively by princes of the houses of Zapolya and Bathory, generally maintaining the superiority. The next chief of the Protestant party was the celebrated Botskay, whose successes against Austria extorted from the emperor an acknowledgment of the independence of T. in 1606. To him succeeded Bethlem Gabor, the determined foe of Catholicism and Austria, who did important service during the Thirty Years' War. Between his son and successor, Stephen, and Ragotski arose a contest for the crown, in which the latter prevailed; but on Ragotski's death, the civil war was resumed, till the complete rout of the Austrians by the Turks, under Kiupruli, placed the sceptre in the hands of Michael Abaffi, who reigned, till his death in 1690, as a vassal of the Porte. The Austrians now again possessed themselves of T., despite the heroic resistance of Ragotski; and though Tekeli (q. v.) succeeded for a brief period in rolling back the invaders, the peace of Carlovitz, in 1699, again put them in possession; and after the death of Michael Abaffi II., in 1713, T. was completely incorporated with Hungary. It was erected into a grand principality in 1765. During the insurrection in 1848, the Hungarians and Szeklers joined the insurgents, and forced T. to reunite with Hungary, despite the opposition of the Saxons; and the Wallachs, still little better than a horde of savages, were let loose over the land to burn, plunder, and murder indiscriminately; the prostration of the country being completed in the following year during the bloody conflicts which took place here between Bem and the Russian troops. In the same year, T. was again separated from its turbulent neighbour, and made a crown land; the portions of it which had, in 1835, been annexed to Hungary being restored, as well as the Transylvanian Military Frontier, in 1851.—For an interesting sketch of the social life, character, mental characteristics, and present condition of the various races of T., see *Transylvania, its Products and its People*, by Charles Boner (Lond. 1865).

TRAP or TRA'PPEAN ROCKS, an important section of the Igneous Rocks (q. v.), associated with Primary and Secondary strata, so called from the Swedish *trappa*, a stair, because these rocks, having resisted, from their greater hardness, the abrading influences which have destroyed the softer sedimentary strata, stand out like huge steps on the faces of the hills and mountains in some places where they occur. Unlike granite, the Trap Rocks are free from silica crystallising as a separate constituent of the rock; from the modern volcanic rocks the structural difference is very slight, consisting only of the manner in which the silicate of magnesia and lime, common to both, is crystallised—in the older rocks appearing as hornblende, while in the newer it exists as augite.

Trap Rocks are composed of felspar and hornblende, and the different varieties founded on the chemical composition of the mass depend on the relative proportion of these two minerals. When the felspar predominates, the rock belongs to the felspathic trap or felstone series; and when the hornblende is abundant, it is a hornblendic trap or greenstone. This latter series contains the best known Trappean Rocks. The dark hornblende preponderates, and gives to the rock a dull green colour, from which it derives its well-known name greenstone, a translation of the German *grünstein*. It has, however, been shewn by Delesse that many Trappean Rocks owe their colour to a dark variety of felspar which exists in them, and such rocks belong rather to the felspathic than to the hornblendic series. Some greenstones are very light green, others are so dark as to appear black, and all intermediate shades of colour occur. These rocks vary also very greatly in texture: in some, the crystals are sufficiently large to be detected with the naked eye; while others are so fine-grained and compact that it is difficult to resolve the separate crystals even with the help of a lens. Experiments have shewn that the size of the crystal in an igneous rock increases in proportion to the length of time during which the mass remains fluid, and so permits the continued crystalline segregation of its various ingredients. The vitreous trap and obsidian would accordingly represent a speedily cooled flow of liquid rock. In fine-grained basalt, the crystalline force has been slightly developed; while greenstones of different textures exhibit its more continued operations in proportion to the coarseness of their texture. The principal varieties of hornblendic trap are greenstone, whinstone, or trap proper. When the crystals are extremely minute, and there is a tendency in the rock to become columnar, it is a basalt. If the felspar is a soda-felspar, either albite or oligoclase, it is diorite. Euphotide, diallage rock, or gabbro, is a compound of Labrador felspar and diallage, a variety of hornblende; it is a coarse, or sometimes fine-grained rock, with a granitic or porphyritic aspect. Hypersthene rock, or hyperite, is made up of Labrador felspar and hypersthene, another variety of hornblende; it is also a granitic-looking rock, very tough, and of a grayish or greenish-black colour: it is very abundant in the Isle of Skye. Different varieties of hornblendic trap are based upon the structure of the rock, as well as upon its chemical composition. Trappean obsidian is not a common rock, but it is occasionally found. Porphyritic trap is more abundant; a very black variety has received the name of metaphyre. Amygdaloid is a trap with round or almond-shaped cavities, filled with agate, calcite, or other minerals, scattered through it. Trap tuff consists of fragments of scoriæ, volcanic dust, and pieces of other rocks, forming a coarse irregular mass, sometimes bound together by a calcareous cement.

The characteristic rock of the felspathic series is felstone, compact felspar, or petrosilex. It is a light-coloured, greenish, or bluish, very compact, homogeneous, and translucent rock, with a flinty-looking appearance. It forms a large proportion of the contemporary intruded Trap Rocks in the Silurian measures of Wales. Clinkstone, or phonolite, is a variety found in layers or slabs which give a metallic ring when struck with the hammer. Aphanite, or cornean, scarcely differs from true felstone, except that it is a more compact and tougher rock. Pitchstone, or retinite, is a vitreous felstone, less glassy than obsidian, and of a green colour and resinous lustre: a dyke thirty feet wide occurs on the eastern shores of the island of Arran, cutting through the sandstone rocks. When distinct crystals of one or more minerals are scattered through an earthy or compact base of felstone, a felspathic porphyry is formed. The ancient red porphyry of Egypt, known as *rosso antico*, belongs to this set of rocks; it consists of a red felspathic base, in which are disseminated rose-coloured crystals of oligoclase, with some plates of blackish hornblende and grains of oxidised iron-ore.

As true igneous rocks come up from below, there is always a connection of some kind between the ejected mass and the inferior source of supply, except when the ejected materials have been subsequently arranged by atmospheric or aqueous agency. Pipes and dykes form such connections, and they are generally associated with tabular masses which have either spread themselves over the surface, or inserted themselves between the beds of the sedimentary strata. When the materials have been mechanically arranged, the igneous rocks are contemporaneous with the deposits in which they occur; but in all cases where strata are cut through by dykes or pipes, or are covered by flows of liquid rock, the igneous rocks are newer than the sedimentary strata with which they are associated.

TRA'PA, a genus of plants, of the natural order *Haloragiaceæ* (q. v.), having a 4-parted calyx, a 4-petallous corolla, and a nut on which the altered calyx appears in the form of spines; the cotyledons very unequal in size. All the species are aquatic plants, with floating habit. *T. natans*, the WATER CALTROPS, is the only European species. It is found in ditches and ponds in the south of Europe, and is grown in ponds in Holland. The floating leaves are rhomboidal, toothed, and smooth; those under water are cut into capillary segments. The fruit has four spines; the kernels are large and almond-like. They are good to eat, either raw or roasted, and somewhat resemble chestnuts in taste. They are often used in soups. The French name is *Marron d'Eau* (Water Chestnut).—*T. bispinosa*, the SINGHARA NUT, affords a great part of the food of the inhabitants of Cashmere, and a tax laid upon it by Runjeet Singh yielded a large sum annually. —*T. bicornis* is much cultivated in China, where the cultivation of aquatic plants is carried on to a degree unknown in other parts of the world, and its fruit is much used for food. In both these species, the nut has only two spines.

TRAPA'NI (anc. *Drepanum*), one of the principal seaports of Sicily, on Cape Trapani, in the north-west of the island; capital of the province of that name, 40 miles west of Palermo. Pop. (1861) 26,334. The town is walled, and defended by a fortress. The streets are wide, and well paved with flagstones. There is a natural harbour, capable of admitting vessels of about 300 tons; a handsome town-house; a tower built by the Saracens; a cathedral; and many churches, some of which contain fine paintings. The inhabitants are engaged in the tunny,

anchovy, and coral fisheries. The coral is brought from the coast of Barbary to T. to be cut and polished for exportation. T. is a busy town, and exports sumach, salt, soda, coral, alabaster, wine, tunny, and anchovies.

Ancient *Drepanum* was probably founded by the Carthaginians, under whom it became an important stronghold. Here took place a celebrated naval engagement between the Romans, under P. Claudius, and the Carthaginians, under Adherbal, 249 B. C., in which the former were completely beaten. In Roman history, the name scarcely appears, but it seems to have flourished in obscurity both then and during the middle ages.

TRAPE'ZIUM (Gr. *trapezion*, a little table) is the general term for a four-sided plane figure, and is synonymous with 'quadrilateral.' But since all four-sided figures which have parallel sides possess distinctive appellations, the term trapezium is frequently restricted to quadrilaterals whose sides are not parallel. The trapezium, in the restricted sense (exclusive of parallelograms), has some remarkable properties: thus, if its sides be bisected, and the adjacent points of bisection joined, the resulting four-sided figure is a parallelogram; the sum of the squares of its diagonals is equal to the sum of the squares of the sides, together with four times the square of the line joining the middle points of the diagonals; if it can be inscribed in a circle (i. e., if its four corners are in the circumference of any circle), the one pair of opposite angles is equal to the other pair, and the sum of the rectangles by each pair of opposite sides is equal to the rectangle by the diagonals; if it can be described about a circle (i. e., if a circle can be made to touch on the interior, each of the four sides), the one pair of opposite sides is equal to the other pair.

TRA'PEZOID, a plane quadrilateral which has two of its sides parallel, and the other two not.

TRA'PPIST ORDER, THE, celebrated among the religious orders of the Roman Catholic Church for its extraordinary austerities, is so called from La Trappe, an abbey of the Cistercian order, founded in the middle of the 12th century. The discipline of this monastery, in common with many others of the more wealthy monastic bodies, especially of those which, by one of the corruptions of the period, were held *in commendam*, had become very much relaxed; and in the 17th c. but little trace of the ancient religious observance remained. In the first half of that century, the abbey of La Trappe fell, with other ecclesiastical preferments, to the celebrated Armand Jean le Bouthelier de Rancé. The circumstances which led this remarkable man to undertake a reform of his monastery, and in the end the establishment of what was equivalent to a new religious order, have been already detailed in the article Rancé (q. v.). It was in the year 1662 that he entered in earnest upon his duties, and commenced his reforms. At first, he encountered decided, and even violent opposition from the brethren; but his firmness and vigour overcame it all. He himself, as an evidence of a complete change of life, entered upon a fresh novitiate in the year 1663; and in the following year, made anew the solemn profession, and was reinstalled as abbot. From this time may be dated the introduction of the new austerities which have characterized the order. The monks were forbidden the use of meat, fish, wine, and eggs. All intercourse with externs was cut off, and the old monastic habit of manual labour was revived. The reform of De Rancé is founded on the principle of perpetual prayer and entire self-abnegation. By the Trappist rule, the monks are obliged to rise at two o'clock A. M. for matins in the church, which lasts till half-past three; and after an interval occupied in private devotion, they go at half-past five to the office of prime, which is followed by a lecture. At seven, they engage in their several daily tasks, indoors or out, according to the weather. At half after nine, they return to the choir, for the successive offices of terce, sext, and none; at the close of which they dine on vegetables dressed without butter or oil, and a little fruit. This meal is succeeded by manual labour for two hours, after which each monk occupies an hour in private prayer or reading in his own cell until four o'clock, when they again assemble in the choir for vespers. The supper consists of bread and water, and after a short interval of repose, is followed by a lecture. At six o'clock they recite complin in choir, and at the end, spend half an hour in meditation, retiring to rest at eight o'clock. The bed is a hard straw mattress, with a coarse coverlet; and the Trappist never lays aside his habit, even in case of sickness, unless it should prove extreme. Perpetual silence is prescribed, unless in cases of necessity. The minor practices and observances are devised so as to remind the monk at every turn of the shortness of life and the rigour of judgment; and the last scene of life is made signal in its austerity by the dying man being laid during his death-agony upon a few handfuls of straw, that he may, as it were, lay aside upon the very brink of the grave even the last fragment of earthly comfort to which the necessities of nature had till then compelled him to cling.

The reformed order of La Trappe scarcely extended beyond France in the first period of its institution. The inmates of La Trappe shared, at the Revolution, the common fate of all the religious houses of France: they were compelled to quit their monastery; but a considerable number of them found a shelter at Valsainte, in the canton of Freiburg in Switzerland. In the vicissitudes of the revolutionary war, they were driven from this house; and a community numbering about 250, together with a large number of nuns, who had been established for purposes of education, found refuge at Constance, at Augsburg, at Munich, and eventually, under the Czar Paul, in Lithuania and White Russia. Later in the course of the war, small communities obtained a certain footing in Italy, Spain, America, England, and, notwithstanding the prohibitory law, even in France, at Mont Genevre. After the Restoration, they resumed, by purchase, possession of their old home at La Trappe, which continues up to the present time to be the head monastery of the order, and numbers nearly 200 members. During the course of the last 45 years, they have formed many establishments in France; a few in Germany; a very considerable one at Mount Melleray, near Cappoquin, in the county of Waterford, Ireland; and others with still more extensive territory annexed in Kentucky, Illinois, and other states of North America. A modification of the T. O., called 'Trappist Preachers,' was established about 25 years since, at Pierre-qui-Bire, near Avallon.—See Gaillardin's *Trappistes; ou l'Ordre de Citeaux au* 19 *Siècle* (Paris, 1844).

TRASH. See SUGAR.

TRASIME'NUS LACUS, the ancient name of an Italian lake (*Lago Trasimeno*, or *Lago di Perugia*) lying between the towns of Cortona and Perugia. It is about ten miles in length by 8 in breadth; the greatest depth is not above 30 feet. The lake has no apparent outlet, and the margins are flat and overgrown with reeds. It is surrounded on all sides by hills, those on the north side, extending

from Cortona to the lake, being known as the Gualandro Hills—the *Montes Cortonenses* of Livy—covered at the present day with oak, vine, and olive plantations. The lake contains three islands. T. L. is memorable chiefly for the great victory obtained by Hannibal in 217 B.C. during the Second Punic War, over the Romans, under their consul, C. Flaminius. Hannibal leaving Fæsulæ, passed close by the camp of Flaminius at Arretium, laying waste the country as he proceeded in the direction of Rome. This, as the Carthaginian general intended, induced the consul to break up his encampment, and follow in pursuit, Hannibal in the meantime taking up a strong position on the hills on the north side of the lake, along which he was passing. The consul, coming up early next morning, when the whole place was enveloped in mist, saw only the troops in front on the hill of *Tuoro*, with whom he was preparing to engage, when he found himself surrounded and attacked on all sides. The Carthaginians thus had the Romans completely in their power, and took such advantage of the opportunity, that 16,000 Roman troops are said to have been either massacred or drowned in the lake, Flaminius himself being among the first who fell: 6000 troops who had forced their way through the enemy, surrendered next day to Maharbal. It is said both by Livy and Pliny that the fury on both sides was so great as to render the combatants unconscious of the shock of an earthquake which occurred during the battle.

TRAS-OS-MO'NTÉS (Beyond the Mountains), a province of Portugal, forming the north-east corner of the country, is bounded on the N. and E. by Spain, on the S. by the river Douro, and on the W. by the Portuguese province of Minho. Area, 3980 sq. m.; pop. (1878) 410,461. It is in the main a cold plateau, with bare mountain masses, broken through by deep romantic ravines; but the port-wine district, known as the *Alto-Douro*, is very pleasant. Considerable quantities of wheat and rye are raised, but the chief products are wine and oil. In several places, the silkworm cultivation is prosecuted with success. Fruits, especially oranges, are produced abundantly in the valleys, and sumach on the mountains, which are also rich in unutilised metallic wealth.

TRASS, a tufaceous deposit of the extinct volcanoes of the Eifel, near Coblenz, resembling the Puzzolana of Naples. Its base consists almost entirely of pumice, in which are embedded fragments of basalt, burnt shale, slate, sandstone, &c., and even numerous trunks and branches of trees. Its formation is accounted for by supposing an eruption to have taken place, with copious evolution of gases, in a lake-basin, and a flood of the mud thus formed to have swept away whatever came before it. Large areas are covered by the T., which has choked up valleys, now partially re-excavated.

TRAVANCO'RE, a protected state in the extreme south of India, bounded on the E. by the states of Tinnevelli and Madura, and on the W. by the Indian Ocean. Area, 4722 sq. m.; pop. 1,011,824. At the southern extremity of the state is Cape Comorin (properly, Kumarin). On the elevations, the soil is light and gravelly; in the valleys, it is in general a deep black mould. Rice, the sago-palm, and vegetables are the principal products. Formerly, the capital was Travancore, a decayed and unimportant town; the present capital is the small town Trivanderam.

TRAVELLERS, LAW AS TO. In the United Kingdom, entire freedom of travelling is one of the rights of the subject. The rights of travellers in regard to the use of roads are stated under the head of Highway (q. v.). Other rights are noticed in connection with Inn (q. v.). With regard to travellers by conveyances, whether by land or sea, if the party conveying is a public carrier, then the following are his liabilities. A public carrier having a stage-coach (and railway companies are on the same footing) does not engage or warrant to convey a traveller with absolute safety, as is the case with respect to goods, but merely to convey without negligence on his part; hence, if the conveyance meets with some accident, resulting in injury to the traveller, the right of the latter to recover damages depends on whether the carrier or railway company has been guilty of negligence. Considering that, in case of a dispute, it is always left to a jury to say whether there was negligence or not, it is a safe maxim, that there is scarcely anything in the form of an accident which is not resolvable by a jury into negligence on the part of the carrier or company; and an injured traveller has seldom much difficulty in throwing the burden on the carrier of proving that there was no negligence on his part, and this proof, for the reasons stated, is seldom successful, at least where the accident arose from a defect in guiding the carriage. In case of accidents not fatal, the party injured has almost always a remedy against the carrier, the chief dispute being as to the amount of damages, the amount legally demandable varying according to the position in life and injury to business caused by the accident. In case of death caused by blamable accident in travelling, there was formerly no remedy available to the executors or relatives, and there is none at the present day; but if the deceased party leave a wife, husband, parent, or child, then these, but no other relations, can sue for damages. In the case of a traveller's proceeding a great distance over several lines of railway, his remedy is entirely against the company with whom he contracted—that is to say, to whom he paid the lump sum, and from whom he obtained his ticket. A carrier may contract not merely to carry a traveller a certain distance by his own conveyance, but to carry him to any part of the world, using for that purpose various other intermediate railways or steamers for the rest of the journey; and in all such cases the only person with whom the traveller contracts is the carrier to whom he paid his fare, who is liable for any accident or negligence, whether occurring on his own part of the line, or on any other part.—As to travellers' luggage, see LUGGAGE.

TRAVELLER'S TREE, or RAVENALA (*Urania speciosa*, or *Ravenala Madagascariensis*), a remarkable plant of the natural order *Musaceæ*, a native of Madagascar, and forming a characteristic feature of the scenery of many parts of that island. The stem resembles that of the plantain, but sends out leaves only on two opposite sides, like a great expanded fan. The lower leaves drop off as the stem grows, and in an old tree the lowest leaves are sometimes thirty feet from the ground. A tree often has twenty or twenty-four leaves, the stalk of each leaf being six or eight feet long, and the blade four or six feet more. The blade of the leaf is oblong, bright green, and shining. The fruit is not succulent, but is filled with a fine silky fibre of the most brilliant blue or purple colour, amongst which are about thirty or forty seeds. Forty or fifty fruits grow in a bunch, and three or four bunches may be seen at once on the tree. The leaves are much used for thatch, and for many other purposes; and the leaf-stalks for the partitions, and often even for the walls of houses. The leaf-stalks always contain water, even in the driest

weather, more than a quart being readily obtained by piercing the thick part of the base of a leaf-

Traveller's Tree (*Urania speciosa*).

stalk, and this water is pure and pleasant. Hence the name *Traveller's Tree.*

TRA'VEMÜNDE. See LÜBECK.

TRA'VERSE, in Fortification, mounds of earth, above the height of a man, and 18 feet thick, placed at frequent intervals on a rampart, to stop shot which may enfilade the face of such rampart. A fire of this nature, in the absence of traverses, would dismount the guns, and prove altogether ruinous. The traverses also give means of disputing the progress of an assailant who has gained a footing on the wall, for each traverse becomes a defensible parapet, only to be taken by storm.

TRAVERSE, in the Law of England, means the denial of fact given by one party in an action to the pleading of his adversary.

TRAVERSING PLATFORM, an arrangement for the more rapid and easy movement of cannon in battery. The gun is either mounted on an ordinary truck-carriage, or on rollers under its trunnions. The truck or rollers work in and out on two parallel iron rails, which rails are mounted on the traversing carriage, and are 16 feet or more in length. Wheels at each end of this platform, or more frequently if the weight of the gun be very great, are placed at right angles to the direction of the rails, and run on circular tramways, which have their centre in the embrasure through which the gun is fired. The rails incline upwards towards the rear, to moderate the gun's recoil. The advantages are, that the leverage for turning the gun is increased by the platform's length, while the circular rails diminish the resistance; that the gun is easily run out for firing on the upper rails; that by its own recoil it runs itself in again for loading; and that a much smaller embrasure is required to give a good compass to the muzzle.

TRA'VERTIN, the Italian name for limestone formed by springs holding lime in solution.

TRA'VESTY (Fr. *travestir*, to disguise, particularly through the effect of *contrast;* e. g., to dress in another sex's or person's clothes; Ital. *travestire*) is a term applied in literature to denote a burlesque representation of something previously executed in a serious and lofty manner. It differs from Parody (q. v.) in this respect, that while the latter changes the subject-matter and the *dramatis personæ*, but mockingly imitates the style of the original, the former leaves the subject-matter partially, and the *dramatis personæ* wholly, unaltered; producing a purely comic effect by the substitution of the mean, the frivolous, and the grotesque in action or speech, for the serious, the noble, or the heroic.

TRAVNI'K, a town of European Turkey, capital of the province of Bosnia, on the Lasva River, 45 miles west-north-west of Bosna-Serai. Its numerous mosques and the castle, which dates from the middle ages, are the principal edifices. It contains 12,000 inhabitants, almost all Mohammedans. The principal branch of industry is the manufacture of sword-blades.

TRAW'LING, a mode of fishing by a net dragged along the bottom of the sea, behind a boat. It is much employed in deep-sea fishing on the coast of England, and by far the greater part of the fresh fish brought to the London market, herring and mackerel excepted, is now obtained by trawling. Trawling has long been practised on some parts of the south coast of England, but of late years this mode of fishing has been adopted much more extensively than before, and has been introduced where it was formerly unknown, particularly on the east coast of England, not without great opposition on the part of line-fishers and others, who have loudly complained of injury done by it to the fisheries by destruction of spawn, and otherwise. The Report of the Commissioners on the Sea-fisheries of the United Kingdom, 1866, sets aside all complaints against it, however, as unfounded; whilst its great productiveness recommends it as advantageous to the public interest. The *Trawl*, or *Beam-trawl*, as

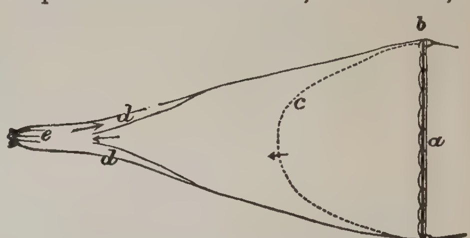


Fig. 1.—Beam-trawl Net:
a, beam; *b*, *b*, trawl-heads; *c*, outline of the ground rope; *d*, *d*, the pockets; *e*, the cod or small end of the net.

it is often called, is a triangular purse-shaped net, about 70 feet long, usually having a breadth of about 40 feet at the mouth, and gradually diminishing to 4 or 5 feet at the commencement of the *cod*, or smaller end of the net, which is about 10 feet long, and of nearly uniform breadth. The upper part of the mouth is secured to a wooden beam about 40 feet long, which keeps the net open; this beam is supported on two upright iron frames, known as the *trawl-heads* or *irons*. The under side of the net corresponds with the upper, except that instead of being fastened to a beam, it is made with a deeply-curved margin attached to the *ground-rope*, the whole length of it in contact with the ground. A trawl has also generally two *pockets*, one on each side, made by lacing together the upper and under parts, so that fish turning back from the cod may be caught in them. The meshes vary in size from four inches square at the mouth, to an inch and a quarter square in the cod. Two stout ropes, of about 15 fathoms each, are fastened, one to the front

of each of the trawl-heads, the other ends united to form a bridle, to which is shackled a warp 150 fathoms long. By this warp the trawl is towed, the quantity of rope paid out depending on depth of water, weather, and other conditions. Trawling is generally in the direction of the tide, sometimes across it, but never against it. The rate of progress is usually only from half a mile to two miles an hour faster than that of the stream. The trawl can only be used with advantage on a sandy bottom or other smooth ground. On rough ground, the net would be torn in pieces. The vessels employed in trawling on the Dogger Bank and elsewhere near the English coast vary in size from 35 to 60 tons. Many of these trawlers, however, stay out at sea for six weeks at a time in all seasons of the year; their fish being packed in ice collected by fast-sailing cutters, and so conveyed to market. Cod, haddock, and other *white-fish* are caught in great numbers by trawling; and some kinds of flat-fish, as soles, are scarcely to be obtained by any other means. Smaller trawl-nets than those above described are used in bays and estuaries. A kind of trawl called the *pole-trawl* was formerly in use

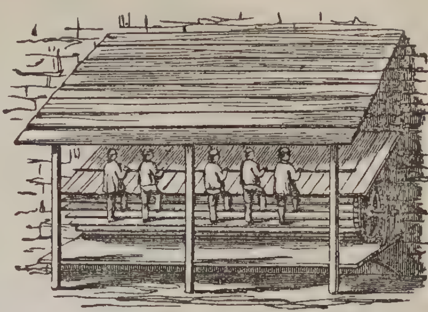
Fig. 2.—Pole-trawl Net.

in some parts of England, but is now used only in the south of Ireland. It is much less effective than the beam-trawl. Instead of a beam, two poles of 25—30 feet long are used, rigged out on the sides of the vessel, to keep the mouth of the net open.

The term trawling is commonly, although incorrectly, employed in Scotland to designate a particular mode of herring-fishing, which, however, is only seine-net fishing (see NETS) on the principle of encircling shoals of fish, as has been practised in pilchard-fishing on the south coast of England from time immemorial. It is of recent introduction in Scotland, and has been opposed by the drift-net herring-fishers, from interested motives, in the same way that beam-trawling has been opposed on many parts of the English coast. The legislature too hastily accepted the views of its opponents; but a Royal Commission having been appointed to inquire into the subject, made a report decidedly favourable to it in 1863; and the judgment of that Commission is sustained by the Report of the Sea-fisheries Commission of the United Kingdom in 1866.

TREACLE. See SUGAR.

TREAD-MILL, an appliance of prison discipline, much in use some years ago in the prisons of Great Britain, the invention of Sir William Cubit, of Ipswich. It consists of a wheel in the form of a long cylinder, furnished with 24 steps round its circumference, and turned on its axis by the tread of prisoners, each of whom may be made to tread in a separate compartment, so boarded off that he can have no intercourse with the rest. The prisoners are assisted and supported by a hand-rail, and cause the wheel to revolve about twice in the minute. The tread-mill has sometimes been made productive by being used to grind corn or turn machinery. It has been found an objection to its use, that it does not admit of being modified to meet the varying strength of individual prisoners; and as an instrument of prison discipline, it has been generally supplanted by the *Crank*, a small flaked wheel, like the paddle-wheel of a steamer, which, on the prisoner turning a handle outside, revolves within a box partially filled with gravel. The amount of strength necessary to each revolution can be regulated by the quantity of



Tread-mill.

gravel used, and a register placed outside the prisoner's cell records the number of revolutions made. The crank is only used when hard-labour is part of the prisoner's sentence.

TREASON (Fr. *trahison*, Lat. *traditio*, from *tradere*, to give up or betray), in the Law of the United Kingdom, is the highest civil crime which a member of the community can commit, being treachery against the sovereign. By the ancient common law of England, there was great latitude as to what was held by the judges to be treason, whereby, says Blackstone (b. iv. c. vi.), the creatures of tyrannical princes had opportunity to create abundance of constructive treasons, that is, to raise, by forced and arbitrary constructions, offences into the crime and punishment of treason, which never were suspected to be such. Thus, the accroaching, or attempting to exercise royal power—a very uncertain charge—has been treated as treason; and killing the king's father or brother, or even his messenger, has also been so treated. The inconvenience of these constructive treasons led to the passing of the statute of 25 Ed. III. c. 2, which attempted to define treason, and it was defined in five forms. 1. When a man compasses or imagines the death of the king, queen, or their eldest son and heir. Under this clause it was held that the husband of a queen-regnant was not included; but it includes a king *de facto*, without regard to his title. The phrase 'compassing and imagining the death of a king,' has given rise to much discussion, but it has been taken to mean the mere purpose or design, as distinguished from the carrying such design into effect; nevertheless, the purpose can only be proved by some overt acts, such as providing weapons or ammunition for the purpose of killing the king, assembling and consulting on the means to kill the king, &c. The law has often, however, been strained, and in arbitrary reigns, even a sermon unpreached was held to convict Peachum; and a paper found in a closet, to convict Algernon Sidney, though merely speculative in its character. 2. Another form of treason is the violating of the king's companion (i. e., wife), or his eldest daughter unmarried, or the wife of the king's eldest son and heir. 3. Another form is that of levying war against the king in his realm, either by taking arms to dethrone the king, or under pretence to reform religion or the laws; by resisting the king's forces; by joining an insurrection, with an avowed design to pull down all enclosures, all brothels, and the like; though such a conspiracy, if aimed at a particular house, would be only a riot. 4. It is also treason to adhere to the king's enemies in the realm by giving them aid and comfort, as by sending

intelligence or provisions, or selling arms. 5. Lastly, it is treason to slay the chancellor, treasurer, or the king's justices of the bench, or in assize, while in their places administering justice. Besides these specific forms of treason, the statute of Edward III. enacted that, if there should be other cases not above specified, the judge should tarry without going to judgment, till the king and parliament should judge it treason or other felony—which was a safeguard against the judges indulging too much in refinements about constructive treason. At a later period, between the reigns of Henry IV. and Queen Mary, the courts returned to the system of inventing constructive treasons, and actually included as such the clipping of money, burning houses to extort money, refusing to abjure the pope, &c. These and other new-fangled treasons were totally abolished by a statute of 1 Ed. VI. c. 12. By a subsequent statute of 1 Anne c. 17, whoever endeavours to hinder the next in the succession under the Act of Settlement, from succeeding to the crown, is to be held guilty of treason; and whoever maliciously affirms another to have right to the crown, otherwise than according to the Act of Settlement, commits treason. Moreover, by 36 Geo. III. c. 7, whoever compasses or intends death or bodily harm to the person of the king, is to be adjudged a traitor. The prisoner is entitled to a copy of the indictment, a list of the witnesses, and counsel for his defense. This right, which prisoners accused of other crimes have not in English law, was conferred by a statute of Will. III.

The punishment of treason is severe and even revolting. The traitor is to be drawn on a hurdle to the place of execution, hanged by the neck, his head then severed from the body, the body divided into four quarters; and the head and quarters to be at the disposal of the crown. But the king may, after sentence, by warrant, change the sentence into beheading. In the case of women, they are only to be hanged. The consequence of a conviction of treason is forfeiture and corruption of blood. The forfeiture affects all the lands and freehold estates, and relates back to the time of the treason committed. The corruption of blood which also ensues has this effect, that an attainted person can neither inherit lands from his ancestor, nor transmit them by descent to any heir, but they escheat to the lord of the fee, subject to the crown's superior right of forfeiture. Not only are the lands forfeited, but the goods and chattels also of the prisoner.

There are certain minor offences which are called misprision of treason, being those closely bordering on treason. Such are offences which consist in the bare knowledge and concealment of treason, without any degree of assent thereto, for any assent makes the party a principal traitor. If a person, knowing of the treason, do not forthwith reveal it to some judge of assize or justice of the peace, this is the crime of misprision of treason. The punishment of misprision of treason is loss of goods and lands during life. Another offence closely related to treason is the wilfully pointing a gun at, or attempting to strike, the person of the sovereign, with intent to injure him (or her); the offence being recently reduced, by statute 5 and 6 Vict. c. 51, to one punishable with three years' imprisonment. There is also a cognate offence created by 11 and 12 Vict. c. 12—that of intending to depose the queen, or levying war against her in order to intimidate her or the Houses of Parliament. The offence of Præmunire (q. v.) was originally the introducing a foreign power into the country, and the name was extended to similar offences. The law of treason in England and Scotland is the same.

The Constitution of the United States defines treason to consist only in levying war against them, in adhering to their enemies, giving them aid or comfort, and is punished with death. No person can be convicted of treason except on the testimony of two witnesses to the same overt act, or on confession in open court.

TREA'SURER, Lord High, the name given to the third great officer of the crown in England, who, in former times, was sole head of the king's exchequer. In the reign of William I. a separate board and court for matters of revenue was appointed after the model of the Exchequer of Normandy, and a treasurer and other officers were appointed for transacting business relating to the royal revenue. Odo, Earl of Kent, was the earliest holder of this office; but the early treasurers were for the most part churchmen. The functions of the treasurer were often discharged by the Chief Justiciary, and the offices of Justiciary and Treasurer seem not to have been completely separated till the reign of Stephen. The office of Lord High Treasurer was for the first time put into commission by James I. in 1612; and from the accession of George I. down to the present time, it has been the practice to vest the office in a Board of Lords Commissioners of the Treasury. See Treasury. In Scotland, a similar office existed prior to the Union; and there were also Lords High Treasurers appointed in Ireland. In 1816, by statute 56 Geo. III. c. 98, on the consolidation of the same offices in England and Ireland, he was constituted the Lord High Treasurer of the United Kingdom.

TREASURER OF THE UNITED STATES is an officer in the Treasury Department, who receives and keeps the moneys of the United States in his office and that of the depositaries, and pays out the same on warrants drawn by the Secretary of the Treasury, countersigned by the First Comptroller, and upon warrants drawn by the Postmaster-General, and countersigned by the Sixth Auditor, and recorded by the Register. He also holds public moneys advanced by warrant to disbursing officers, and pays out the same upon their checks.

TREASURE-TROVE is the finding of hidden treasure in the earth; the word treasure meaning coin, gold or silver plate, or bullion. By the law of England, he who finds such things hidden in the earth is not entitled to them, but they belong to the crown. This is an exception to the general rule, that he who first finds a thing, whose owner is unknown, is entitled to keep it; and accordingly the exception is construed strictly, so that if the coin, &c., is not hidden in and covered by the earth, the finder, and not the crown, is entitled to it. If it is treasure-trove in the strict sense above described, then it is the duty of the finder to give notice to the crown; and to conceal it or appropriate it is an indictable offence, punishable by fine and imprisonment.—In Scotland, the rule is the same, and the finder is bound to inform the sheriff of the finding. It is not so generally known as it ought to be that the crown is in the practice of paying to the finder the value of the property, on its being delivered up; from misapprehension of this matter it is believed that many curious relics are lost by their finders consigning them to the melting-pot.

TREASURY, that department of the executive of the government of the United Kingdom which has the control of the revenue and expenditure of the country. The head of the Treasury was in former times an officer called the Lord High Treasurer (see Treasurer, Lord High), but his office has ever since the accession of George I. been executed by Lords Commissioners, who have become his permanent representatives. The Treasury Board

now consists of the Prime Minister (generally styled First Lord of the Treasury), the Chancellor of the Exchequer, and three junior Lords of the Treasury, who have usually seats in parliament, as have also the two joint-secretaries of the Treasury. The First Lord being the head of the administration, his duties are not limited to the Treasury, which is chiefly conducted by the other members of the Board. The Chancellor of the Exchequer, who holds under a distinct patent the office of Under-treasurer, is the effective head of the Treasury, exercising the most responsible control over the expenditure of the different branches of the service, as also over all works demanding unusual outlay in the naval, military, and civil departments, either at home or in the colonies. He prepares an annual estimate of the expenses of the country, and of the ways and means by which they are proposed to be met; and this statement, known as the Budget, is submitted by him to the House of Commons. The Prime Minister, when a member of the House of Commons, has occasionally held at the same time the office of Chancellor of the Exchequer. The duties of the junior Lords are in a great measure formal: the heaviest portion of the executive functions of the Treasury devolves on the Secretaries.

The function of payment has ever since the Restoration been completely separated from the custody of the public revenue, the former only being vested in the Treasury, while the latter belongs to the Exchequer. By an arrangement effected by 4 and 5 Will. IV. c. 15, the revenue flowing into the Treasury is paid into the Bank of England, to the credit of the Comptroller-general of the Exchequer, and all payments on the public account are made pursuant to a warrant or order of the Treasury. No moneys voted by parliament can be drawn from the Exchequer without the warrant of the Treasury Board, nor can any payment be made from the civil list without its authority.

The duties of the Treasury Board are numerous. The supplies for the army, navy, and civil service are issued under its authority. In virtue of various statutes, it has the regulation of the salaries of newly created officers in other departments, and of the number of officers in the establishments for new branches of the public service. The duties of the Treasury also comprise the examination of the expenses of legal establishments, sheriffs, county courts, and criminal prosecutions. All payments for civil salaries, allowances, and incidental charges payable in England, and all payments for the army, navy, and ordnance, are made upon the special authority of the Treasury by the Paymaster-general. The Boards of Customs and Inland Revenue, and the Post-office, are subject to its general authority. The office of Woods and Forests now discharges many of the duties which formerly devolved on the Treasury, but is subject to its regulations. The establishments of colonial and other offices are also subject to the control of the Treasury with regard to their expenses. The Treasury may be appealed to against the decisions of subordinate departments in all cases connected with the receipt of revenue. The Treasury possesses the patronage of the departments immediately subordinate to it. The church patronage of the crown—except that which belongs to the Lord Chancellor—is usually disposed of on the advice of the First Lord of the Treasury; and the Foreign and Colonial Secretaries, in all important appointments falling under their patronage, are in the practice of consulting the First Lord of the Treasury.

TREATY, in Public Law, an agreement of friendship, alliance, commerce, or navigation, entered into between two or more independent states. Treaties have been divided by publicists into *personal* and *real*, the difference being that the former relate exclusively to the persons of the contracting parties, for example, treaties guaranteeing the throne to a particular sovereign and his family, and the latter are treaties for national objects, independent of the rulers of the state. While personal treaties expire with the death of the sovereign, or the extinction of his family, real treaties bind the contracting parties independently of any change in the sovereignty of the states. The constitution of each particular state must be looked to, to determine in whom the power of negotiating and contracting treaties with foreign powers resides. In monarchies, whether absolute or constitutional, it is usually vested in the sovereign. By the constitution of Great Britain, the exercise of this power is subject to parliamentary censure: ministers who advise the conclusion of any treaty which shall afterwards be judged derogatory to the honour, or disadvantageous to the welfare of the nation, being liable to impeachment, a proceeding of which English history affords numerous instances; as the impeachment of De la Pole, Earl of Suffolk, in 1451, for making a convention of peace without the assent of the privy council; of Wolsey, in 1529, by the House of Lords, for making treaties without the king's knowledge; and of the Earl of Orford by the Commons, in 1701, for advising treaties for dividing the dominions of Spain. In republics, the chief magistrate, senate, or executive council is intrusted with the exercise of this sovereign power. The constitution of the United States of America (art. ii. sec. 2) vests it in the president, with the advice and consent of the senate. No special form of words is necessary for the validity of a treaty; but modern usage requires that an agreement which has originally been verbal, should as soon as possible be committed to writing. There are certain compacts between nations which are included in the exercise of a general implied power confided to certain public agents as incidental to their official position. Such are the acts of generals or admirals limiting hostilities by truces, capitulations, or cartels for the exchange of prisoners, which do not require the ratification of the supreme authority, unless there be a reservation making that necessary. In other cases, however, a public minister or other diplomatic agent is not entitled to conclude or sign a treaty with the foreign power to which he is accredited, without a full power independent of his general letter of credence. Even in the case of a treaty concluded with full powers, it is often considered expedient to have a special ratification by the sovereign, or other proper authority of the state contracting.

A treaty is considered to be extinguished when one of the contracting powers loses its existence as an independent state, when the internal constitution of either state is changed so as to make it inapplicable; and in case of war between the contracting parties, unless the stipulations of the treaty have been expressly with a view to the rupture. As there is often a difficulty in distinguishing stipulations perpetual in their nature, from those that are extinguished by war, it is common to insert clauses in treaties of peace reviving and confirming the treaties formerly subsisting between the contracting parties.

A Treaty of Guaranty is an engagement by which one state promises to aid another when it is disturbed, or threatened to be disturbed, in the peaceable enjoyment of its rights by a third power.

Treaties of alliance may be offensive or defensive; in the former, the ally engages generally to co-operate in hostilities against a specified power, or against

any power with which the other may be at war; in the latter, the engagements of the ally extend only to a war of aggression commenced against the other contracting party.

The execution of a treaty is occasionally secured by hostages; as at the peace of Aix-la-Chapelle, in 1748, when several peers were sent to Paris as hostages for the restoration of Cape Breton by Great Britain to France.

TRE'BBIA, a small but famous stream of Italy, rises in the Ligurian Apennines, near Montebruno, flows northward through a mountain valley for the greater part of its course, and joins the Po, two miles west of Piacenza. Its entire length is about 50 miles. Here Hannibal decisively defeated the Roman consul Sempronius, 218 B.C.

TRE'BIZOND, or TREBISOND (in Turkish, *Tarabezûn*), is a Turkish eyalet in the north-east of Asia Minor, stretching along the south-east shore of the Black Sea for 70 miles, with an estimated pop. of 250,000. The surface is mostly mountainous, the slopes towards the sea being thickly wooded. The eastern portion of the eyalet is known as Lazistan, from its inhabitants, the Lazi, a savage vindictive race, distinguished among their neighbours for their barbarous manners, predatory habits, and intense hatred of Russia, whose frontier forms the eastern boundary of their country. The chief places of T. are Tchuruksû, Batum, Khopah, Atina, Rizeh, and Surmeneh. The chief town of the eyalet is TREBIZOND, a flourishing seaport city, on the Black Sea coast, about 110 miles northwest of Erzerum. It is surrounded by walls of great extent, which enclose numerous gardens as well as the town itself, and is inhabited by a pop. of 20,000—30,000, chiefly Moslems. Outside the walls are various suburbs, where most of the Christian inhabitants reside, and in which the principal bazaars and khans have been established. The city is defended by several forts along the walls, and by a fortified citadel perched upon a high rock on one side of the town. It possesses an excellent harbour, which, however, is only considered safe during the summer months, the roadstead of Platena, seven miles to the west, being employed for the rest of the year. There are numerous mosques and 'medresses,' ten churches for Greek Christians, copper foundries, dye-works, &c. The geographical position of T. is, in a commercial point of view, rivalled only by that of Alexandria, and has made it the great entrepôt of the commerce between Eastern Europe and Central Asia, and the second commercial city of the Turkish Empire. European goods are brought hither, since 1836, by regular services of steamers from Constantinople and the mouths of the Danube; and those of Asia by caravans from Erzerum, Tabriz, and Syria. In 1859, the imports amounted to £3,729,730; and the exports to £3,898,052; but in 1867 the imports had declined to £1,876,812, and the exports to £1,519,811. The arrivals and departures declined from 626 to 386 vessels. The goods brought overland embrace silk, wool, tobacco, wax, gall-nuts, oil, opium, drugs of various kinds, honey, timber, carpets, and shawls; and those arriving by sea are principally cotton cloths, glass, cutlery, firearms, as well as grain, iron, tin, spices, &c. T. is the ancient *Trapezus*, and was founded by a colony from Sinope; it was a flourishing town when Xenophon arrived there in his famous retreat from Persia, and was at that time under the dominion of the Colchians. Conquered from Mithridates by the Romans, it rapidly rose in importance, became a free city, was made by Trajan the capital of Pontus Cappadocicus; and, by the same enlightened ruler, was provided with a larger and better harbour. On the capture of Constantinople by the Crusaders in 1204, and the expulsion of the Comnenian emperors, one of the imperial family, Alexis, established himself at T., where he had previously exercised the functions of governor, and founded a state known as the *Empire of Trebizond*, which stretched from the Phasis to the Halys, and maintained its independence against the Turks till 1462, when the last emperor was defeated and captured by Sultan Mohammed II.

TREBLE, the highest part in harmonised music, which in general contains the melody, and is sung by a Soprano (q. v.) voice. The treble or G clef

is placed on the second line of the staff, indicating that the note G occupies the line encircled by its lower curve. It is one of the two clefs in use in music for keyed instruments.

TRE'DEGAR, a market-town on the north-west border of Monmouthshire, 18 miles north-west of Newport. It stands in the midst of a district with extensive iron-works and coal-mines, which give employment to the great mass of the inhabitants. Pop. about 15,000.

TREDGOLD, THOMAS, a celebrated English authority on architecture and engineering, was born at Brandon, a small village 2½ miles south-west of Durham, 22d August 1788. At the age of 14 he was apprenticed for six years to a cabinetmaker; but devoted his leisure time to the study of the principles of architecture, and kindred subjects. In 1808, he went to Scotland, where he worked as a journeyman carpenter for five years; then removed to London to his relative Mr Atkinson, the architect to the Ordnance Board, with whom he laboured till 1823, by which period his private business had increased so much that he commenced business on his own account as a civil engineer. During the ten years of T.'s residence with Mr Atkinson, he studied with redoubled zeal, and obtained a thorough acquaintance with mathematics, chemistry, mineralogy, and geology. He died from pure exhaustion of nature, 28th January 1829, at the early age of 40. T.'s scientific contributions to periodicals range over a wide field; but his great and valuable works are *The Elementary Principles of Carpentry, a Treatise on the Pressure of Beams and Timber Frames, the Resistance of Timber, the Construction of Floors, Roofs, Centres, and Bridges* (4to, 1820; 2d ed., 1828); and the *Strength of Cast Iron* (1821; 2d ed., 1824; 3d ed., 1831). His other works, the *Principles of Warming and Ventilating Public Buildings*, &c. (1824); *Practical Treatise on Railroads and Carriages* (1825); a pamphlet entitled *Remarks on Steam-navigation*, &c. (1825); and *The Steam-engine* (1827), were also received with special favour, and of the first and last of them new editions were speedily required.

TREE, the name given to those plants which live for many years, and have woody stems and branches, the stem being generally single, and bearing a head of branches and twigs; whereas Shrubs (q. v.) have generally a number of stems springing from one root. The terms tree and shrub are not, however, of very exactly defined signification; and many shrubs, under certain circumstances, assume the form of trees, either naturally or by the help of art; whilst trees are, in other circumstances, converted into shrubs. The common hawthorn, for example, is very often a mere shrub, but sometimes appears as a tree, with stem and head as perfect as the greatest monarch of the forest. The gooseberry bush is usually trained in our gardens in a tree-like

habit, notwithstanding its small size, and the shortness of its stem; this, however, is entirely artificial, its natural habit being that of a shrub, to which, but for the gardener's knife, it would almost certainly relapse in a single year. The greater number of trees are exogenous. Palms are almost the only endogenous plants to which this name can be given. Very different from the ordinary exogenous trees are the Gymnogens (q. v.) of Lindley—firs, pines, yews, &c. Trees are found in all climates except the coldest, but the number of species, as well as the luxuriance of the forests, is greatest in the tropics. As we advance towards the polar regions, or ascend high mountains, trees disappear before other forms of vegetation. The different characters of trees affect very much the landscape of the countries in which they grow; some countries, and particularly in northern parts of the world, being covered with sombre pine forests, whilst others abound in ash, beech, and similar trees of verdant foliage. Every kind of tree has its peculiar character, not only in its foliage, but in its general form and its mode of branching. An ash is as easily distinguished from an elm, by a practised eye, in winter, when destitute of leaves, as in the full foliage of summer. Some trees attain a very great age, but the ordinary duration of life is very different in different species. There are trees in England which are supposed to be more than a thousand years old, and are still healthful and flourishing. Oaks and yews are amongst the trees of longest life. The Baobab of Africa is also regarded as a very long-lived tree.

No acotyledonous plant assumes the character of a tree, except a few ferns, known as Tree Ferns.

TREE FERNS are ferns with tree-like woody stem, and a head of fronds resembling the leaves of palms. They are found only in tropical and subtropical countries, many of which, however, are quite destitute of them. One species, *Alsophila*

Tree Fern.

giganlea, which has a thick black trunk surmounted by a feathery crown, is found in the Himalaya, at an elevation of 7000 feet, and might be introduced with some probability of success into Britain. The soft central part of the stem of *Cyathea medullaris* an article of food in New Zealand. Tree Ferns are a characteristic feature of the vegetation of New Zealand.

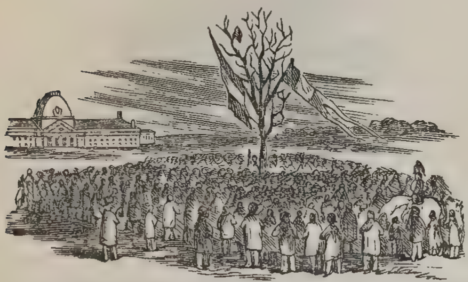
TREE-FROGS (*Hyladæ*), a family of tailless *Batrachia* (q. v.), of the suborder *Arcifera*, separated from the true frogs (*Raniformia*) by the presence of arched cartilages on the sternum. They generally possess dilated discs or suckers at the tips of the toes

Tree-frog (*Hyla viridis*).

which are covered with a viscid secretion, and enable the animals to climb trees. Most of them are arboreal; they are of various sizes, more elegant in form than the true frogs, of brighter colours, and more active habits. They feed on insects, which they pursue on the branches and among the leaves of trees or shrubs, stealing towards them, and suddenly springing upon them. They deposit their spawn in water, like other batrachians—some of them on the edges of leaves hanging over water—and hybernate in mud. Their croaking is louder than that of true frogs, and the traveller is sometimes amused by hearing it from the tops of high trees. No species of Tree-frog is found in Britain; one occurs in the middle and south of Europe; it is also found in Asia and the north of Africa; in the warmer regions of the Old World they are replaced by Ranoid genera adapted for tree-life. They are found more abundantly in America, and occur in Australia, their true home being in these continents. The TREE-FROG of Europe (*Hyla arborea*) —*Rainette* of the French—is found chiefly in moist woods, and in hedges near water. Although a small creature—one of the smallest of European frogs—it can make a spring of more than a yard in height to seize an insect. It becomes very noisy on the approach of rain, and is often kept in confinement, to serve as a weather indicator. Very similar to it is the COMMON TREE-FROG of North America (*H. versicolor*), which is abundant in the middle and northern parts of the United States as far west as the Mississippi, but is replaced in the south by the GREEN TREE-FROG (*H. viridis*), whilst other species are found in different parts of the country.

TREES OF LIBERTY. The custom, peculiar to almost all the nations of Europe, of celebrating the beginning of spring and various national and ecclesiastical festivals by setting up green boughs, led, during the war of independence in the United States, to the habit of planting poplars and other trees as the symbol of growing freedom. This example was imitated during the French Revolution. The Jacobins in Paris are said to have planted the first tree of liberty in 1790; and the custom spread rapidly through the whole of France. These trees,

crowned with the cap of liberty, were soon to be found in every village, while the people danced round them, singing revolutionary songs, and regarded them as the rendezvous of the patriots. Poplars were at first employed, but afterwards oaks, were substituted in their place. This custom was regulated by a decree of the Convention, and diffused over foreign countries by the republican armies. During the Reign of Terror, thousands lost their lives under the pretext of having injured a tree of liberty. During the Empire, this custom, like all others that had originated during the Republic, was completely suppressed. In the July revolution of 1830, trees of liberty were again set up, particularly at Paris; but the populace took no interest in the matter. During the February revolution of 1848, trees of liberty once more came into



M. Ledru Rollin addressing the people under the Tree of Liberty in the Champ de Mars, 1848.

vogue at Paris and other places where the inhabitants held republican principles. They were generally hung with tri-coloured ribbons, circles, and triangles, the symbols of unity and equality, and surmounted with the cap of liberty. In Paris, on the occasion of erecting a tree of liberty, a priest was frequently conveyed to the spot for the purpose of consecrating it. After most of the trees of liberty had fallen during the conflicts in the streets of Paris in June 1848, government issued an order for their removal from all places where they impeded traffic. Before the end of the year, they had entirely disappeared. Numerous trees of liberty were likewise erected in Italy during the revolution of 1848 and 1849, but fell again as the different insurrections were quelled. A very learned and interesting treatise has been written on this subject by the Abbé Grégoire.

TRE'FOIL, a name given to many herbaceous plants with leaves of three leaflets, as Clover (q. v.), Lotus (q. v.), Medick (q. v.), Buckbean (q. v.), &c.

TREFOIL, in Heraldry, is a frequent charge, representing the clover-leaf, and is always depicted as *slipped*, i. e., furnished with a stalk.

Trefoil in Heraldry.

Trefoil in Architecture.

TREFOIL, in Architecture, a three-lobed aperture in tracery, &c.

TRE'LLIS, an open grating or lattice-work, formed in wood, iron, &c.

TREMATO'DA, or **TREMATODE WORMS**, constitute, according to Dr Cobbold's system, the second order of the sub-class *Sterelmintha*, of the class *Helmintha*. This order, as the Greek word *Trēmatōdes* indicates, is characterised by the possession of certain pores or openings. All the animals included in it have soft, roundish, or flat bodies, and their visceral organs are lodged in the parenchyma of the body. They have a mouth and an intestine, which usually soon bifurcates, the two primary digestive tubes usually running parallel to one another, until they reach the caudal extremity, giving off in their course branches, which like themselves, terminate in blind sacs. Most of the T are hermaphrodites. They seldom attain to a large size, but are usually visible to the naked eye; the largest species vary from one to five inches in length, while the former forms scarcely exceed the $\frac{1}{100}$th of an inch at their longest diameter.

The Trematoda, or flukes, as they are popularly called, from their resemblance in form to small flukes or flounders, are not parasitic during the whole period of their existence; 'for while passing through the cycle of their life-development, they frequently change their residence, at times inhabiting either open waters, or the dewy moisture of low pasture-grounds. They perform active and passive migrations from parasitic to non-parasitic abodes; and during their larval wanderings in search of a final resting-place which should prove suitable to their adult condition, they provisionally occupy the bodies of different kinds of invertebrata.' —Cobbold's *Entozoa*, 1864, p. 15. In his *Synopsis of the Distomidæ* (published in 1861), Dr Cobbold recognises 344 species of flukes, of which 126 belong to fishes, 47 to reptiles, 108 to birds, 58 to mammals, and 5 to the invertebrata. He now believes that, at the very lowest possible estimate, we must assume the order to contain 400 species, which may be divided into the five families of *Monostomidæ*, *Distomidæ*, *Tristomidæ*, *Polystomidæ*, and *Gyrodactylæ*—names which are based, except in the last case, on the number of their pores or oval suckers.

Van Beneden arranges these families into (*a*) *Monogenea* and (*b*) *Digenea*, the development in the former being simple, while in the latter there is an alternation of generation, the nurses and larvæ living chiefly in molluscs, while the adult animals chiefly live in the bodies of vertebrate animals. The *Monostomidæ* and *Distomidæ* belong to the latter, and the others to the former group. The family of *Distomidæ* embraces the principal and best-known genera of the order *Trematoda*, and its members are at once recognised by the presence of two pores or suckers; one, the anterior, being connected with the mouth; and the other, termed the acetabulum, being usually placed on the ventral surface, in the middle lines.

The following members of this order are of special interest, as very liable to infest man. *Fasciola hepatica*, described and figured in the article FLUKE, is not only common in all varieties of grazing-cattle, and especially the sheep, but has been found in the horse and ass, in the hare and rabbit, in the squirrel, beaver, kangaroo, &c., and is occasionally met with in man, not only in the liver and gall-bladder, but beneath the skin in various parts, as, for example, in the sole of the foot, behind the ear, and in the scalp. For an excellent account of the anatomy and development of this parasite, the reader is referred to Cobbold, *op. cit.*, pp. 147—169. See ROT. *Distoma lanceolatum* is a species which is by no means uncommon in the sheep and ox, and has been found on at least three occasions in the human subject. *Distoma ophthalmobium* has been occasionally found in the lens of the human eye. *Distoma hæmatobium*, or *Bilharzia hæmatobia*, as Dr Cobbold

terms it, is the only known trematode which is not hermaphroditic.

The male is a cylindrical worm, measuring only

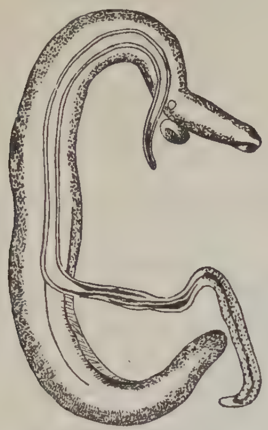


Fig. 1.—*Bilharzia hæmatobia*, male and female: Considerably magnified.

about half an inch in length; while the female is filiform, longer, and much narrower than the male, being about ¾ths of an inch in length. The first specimens were found by Bilharz of Cairo in the portal system, and the worm has since been found in the veins of the mesentery, bladder, and other parts. This parasite is common not only along the borders of the Nile, but in South Africa and the Mauritius. It is so common in Egypt, that in 363 examinations of the body after death, Griesinger found it no less than 117 times.

The principal feature of the disease caused by this worm consists in a general disturbance of the uropoietic function. Diarrhœa and hæmaturia occur in advanced stages of the complaint, being also frequently associated with the so-called Egyptian chlorosis, colicky pains, anæmia, and great prostration of the vital powers. The true source of the disorder, however, is easily overlooked, unless

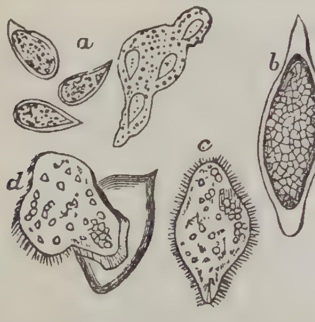

Fig. 2.—Eggs and Embryos of *Bilharzia hæmatobia*: *a*, three ova (× 50 diam.) and a portion of mucous membrane with eggs attached (× 25 diam.); *b*, egg with segmented yelk; *c*, free embryo; *d*, ruptured egg with embryo escaping (× 150 diam.).—From Dr John Harley.

a careful microscopical examination be made of the urine and other evacuations. If blood be mixed with these, and there also be a large escape of mucus, a minute inspection of the excreta will scarcely fail to reveal the presence of the characteristic ova of *Bilharzia*.—Cobbold, *op. cit.*, p. 202. Dr J. Harley has published several excellent papers 'On the Hæmaturia of the Cape of Good Hope, produced by a Distoma,' which is undoubtedly the *Bilharzia*.

Several other trematodes occasionally occur in the human subject.

TREME'LLA, a genus of Fungi, of the division *Hymenomycetes*, soft and gelatinous, of no very determinate form, mostly growing on decaying wood. Several species are found in Britain. In some places, they receive such popular names as Witches' Meat and Witches' Butter. Superstitious notions have been connected with them, and a medicinal value altogether imaginary has been ascribed to them.

TRE'MOLITE, a mineral regarded as a variety of Hornblende (q. v.). It is composed of silica, magnesia, lime, and a very little fluoric acid.

TRE'MOLO, TREMA'NDO (Ital. trembling), in Music, an expression indicating that a note or a chord is to be reiterated with great rapidity for an indefinite number of times, so as to produce a tremulous sort of effect. In singing, *tremolo* effects may on rare occasions be introduced with advantage, but are often resorted to by inferior singers as an artifice to conceal defects of tone and style.

TRE'NAILS, pieces of wood which are used as nails in ship-building. They are usually about 15 or 18 inches in length, and when completed, at least 1 inch in thickness. They are made chiefly of locust-wood (*Robinia pseudo-acacia*), or of oak; the former are imported from North America, the latter from Northern Europe. Great Britain imports of these small pieces of wood as much as £5000 worth annually.

TRENCH. See SIEGE.

TRENCH, RICHARD CHENEVIX, Archbishop of Dublin, divine and scholar of the Church of England, belongs to an Anglo-Irish family of Galway, the Trenches of Woodlawn, and was born at Dublin, 9th September 1807. He was educated at Harrow and Trinity College, Cambridge, where he graduated in 1829. After travelling for a few years, he became a country curate; and in 1837 or 1838, published two volumes of poetry, which had at least the merit of imitating Wordsworth, and were favourably received. One of the poems, the *Story of Justin Martyr*, is even yet faintly remembered. In 1845, T. was presented to the rectory of Itchin Stoke; in 1847, he became Theological Professor and Examiner in King's College, London; in 1856, Dean of Westminster; and in 1864, on the death of Whately, Archbishop of Dublin. T. has written extensively and well. He has a quick, keen understanding; his scholarship is varied and choice, though not sufficiently precise or scientific for philological purposes; his fancy, sometimes poetic, and always picturesque, enables him to invest the dry discussion of words with a peculiar fascination; and if the results of his etymological inquiries are not always sure, the processes are invariably pleasant. As a literary critic, T. is both acute and elegant. His principal works are: *Notes on the Miracles* (1846), *Notes on the Parables* (1841), *The Lessons in Proverbs* (1853), from all of which his professional brethren have borrowed liberally for the work of the pulpit; *The Sermon on the Mount illustrated from St Augustine* (1844), *Sacred Latin Poetry* (1849), *St Augustine as an Interpreter of Scripture* (1851), *Synonymes of the New Testament* (1854), *The Epistles to the Seven Churches of Asia Minor*, *An Essay on the Life and Genius of Calderon*, *Deficiencies in our English Dictionaries*, *Glossary of English Words used in*

different Senses (1859), *The Study of Words* (1851), and finally, the *Remains of Mrs Richard Trench* (1862), his mother. In 1832 he married his cousin, the Hon. Frances Mary Trench, sister of Lord Ashtown. [Died in 1886.]

TRENCK, FRANZ and FREDERICK VON DER, were German barons and soldiers, whose adventures, recorded in autobiographies, have secured for them a world-wide fame. They were cousins, descended from an ancient house of East Prussia, and although placed from infancy under circumstances altogether different, exhibited a striking similarity of character. Both were braggarts, both were subject to fits of uncontrollable passion, and both told premeditated lies.

BARON FRANZ was born in Reggio, in Calabria, on 1st January 1711, when his father was an Austrian general. When 17, he received a commission as a cavalry officer, fought duels, and cut off the head of a man who refused to lend him money. He had to flee in consequence, and he went to Russia, where he was made a captain of hussars. He was then a formidable young giant of 6 feet 3 inches; and it is highly probable that he knocked down his commanding officer, as he says he did, for rebuking him. He adds that he was placed under arrest while an engagement was going on; that Marshal Münnich happening to pass, he called out that if set free and pardoned he would bring back three Turks' heads in an hour; that he was set free, and brought back four Turks' heads suspended from his saddle. This story may or may not be true; but certain it is that he was cashiered not long afterwards, and returned to settle on his estates in Croatia. There it is we first meet with the T. of history. The Turkish frontier was overrun with banditti. T. armed and drilled 1000 of his tenants, whom he called Pandours, and by their means succeeded in restoring order. He then offered the services of his regiment to Maria Theresa, and his aid was accepted. In 1740, he took part in the Silesian war at the head of his men, and perpetrated the most atrocious deeds of rapine and cruelty. There had been no such monster, says Mr Carlyle, since Attila and Genghis. On the 7th of September 1742, he attacked Cham, a fine trading town in neutral territory, this act being, of course, in defiance of all law and discipline; and he completely annihilated it. After the battle of Sohr, in September 1745, he offered to capture Frederick the Great, and bring him a prisoner to the Austrian camp. He failed in the enterprise, with great loss of men, but he secured the king's tent and much valuable booty. Suspicions were, however, entertained of his being in communication with the enemy, and he was tried by court-martial. He was imprisoned at Vienna, but made his escape with the assistance of the Baroness Lestock, who bribed the jailers to allow him to be conveyed in a coffin as if dead beyond the city walls, was again captured at Bruges, and reimprisoned at Grätz, where he took poison, and died on 4th October 1747. —See Carlyle's *Life of Frederick the Great;* and *Mémoires du Baron Franz de Trenck* (Par. 1787), written by himself.

FREDERICK VON DER T. was born at Königsberg, in 1726, and was the son of a major-general in the Prussian service. He distinguished himself at the university. At 16, he became a cornet in the guards; and two years afterwards, the Princess Amalie, who saw him at a ball, we are told, conceived a violent passion for him. To this he attributed the antipathy the king afterwards entertained towards him. There was, however, a much better reason: he was detected in a correspondence with his Austrian cousin, not long before the attempt to capture the king, and arrested. Mr Carlyle shews that the baron had been in prison three months, and was there when the battle of Sohr took place, although he vividly describes his own adventures in the fight. He was accused of this lie in his own time, and admitted that he must have made a mistake! 'He had nothing but his poor agitated memory to trust to.' He was released on 24th December 1763, and afterwards settled at Aix-la-Chapelle, where he married the burgomaster's daughter, and went into business as a wine-merchant. He published his Memoirs in 1787. The book was translated into all languages, and T. became the most famous personage of his time. The ladies at Paris, Berlin, and Vienna wore bonnets, dresses, and rings *à la Trenck;* and no less than seven plays, founded on his adventures, were brought out on the French stage. In 1792, he went to Paris, and became a zealous adherent of the Mountain party. He was, however, suspected, and thrown into prison. Soon after rumours in circulation among the prisoners, that the Prussians were advancing on Paris, and carrying all before them, were traced to T., who was in consequence condemned. He was guillotined near the Barrière du Trône, July 26, 1794. On the scaffold, although 69 years of age, he manifested the ungovernable passion which had characterised him through life. He harangued the mob; and at length the executioner had by force to hold his head by the gray hair on the block, to meet the fatal stroke. —See Chambers's *Book of Days,* vol. i. p. 261; Carlyle's *Frederick the Great,* vol. iv.; *Friedrich Trencks Werkwürdige Lebensgeschichte von ihm selbst beschrieben* (2 vols., Berl. 1787); and *Leben und Thäten der Trenke,* by Watermann (2 vols., Leip. 1837).

TRENT, a river of the midland counties of England, rises on the north-west border of Staffordshire, about 10 miles north of Burslem, and at a height of about 600 feet above sea-level. It flows first south-east to the border of Derbyshire, and afterwards in a general north-east direction through the counties of Derby, Nottingham, and Lincoln, to a point about 8 miles east of the town of Goole, where it unites with the Ouse (q. v.) to form the Humber (q. v.). It receives the Derwent, Idle, and Tarn from the west, and the Soar from the south; its length is 170 miles, for 120 miles of which, from its mouth up to Burton-on-Trent, it is navigable for barges.

TRENT (Ital. *Trento,* Ger. *Trient,* Lat. *Tridentum*), a walled town of Austria, in the southern part of the Tyrol, capital of the circle of the same name, is situated on the left bank of the Adige (here spanned by a wooden bridge 146 feet long), in a beautiful and fertile valley, surrounded by high limestone hills, 46 miles north of Verona. In its general aspect, as well as its architecture, T. is quite an Italian town; and with its spires and towers, ruined castles and ancient embattled walls, it presents an imposing appearance from a distance. The *Piazza Grande,* near the Cathedral, is adorned with a splendid fountain of red marble, surmounted by a colossal statue of Neptune with his trident. The cathedral, begun in 1212, is a beautiful specimen of the Romanesque style of Lombardy, with a few features suggestive of the contemporary German style; united to it is a fragment of the episcopal palace of the 12th century. The Church of Santa Maria Maggiore is built on the site of the council-chamber in which the famous 'Council of Trent' held its sittings. Among other public buildings are the Church of the Jesuits, ornamented with the richest foreign marble; the New Theatre (holding 1400 people; the town-hall; and the Palazzo Buonconsiglio adjoining the town, a noble specimen of the feudal architecture of North Italy, now

occupied as a barrack. Its benevolent and educational establishments are numerous. T. carries on considerable manufactures of silks, wine, tobacco, and sugar, and has a large transit-trade. Pop. 17,000.

The ancient *Tridentum*, or *Tridente*, derived its name from the *Tridentini*, an Alpine tribe, whose capital it was, and has, in all probability, no connection whatever with the *trident* of Neptune (as is commonly supposed). Conrad the Salic bestowed on the prince-bishops of T. the temporal rule of the valley of the Adige, and under them T. rose to great prosperity and importance. It is still the see of a prince-bishop.

TRENT, Council of, the last in order of the assemblies regarded by the Roman Catholic Church as ecumenical or general, and the great repository of all the doctrinal judgments of that communion on the chief points at issue with the reformers of the 16th century. Very early in his conflict with Pope Leo X., Luther had appealed from the pope to a general council; and after the failure of the first attempts at an adjustment of the controversies, a general desire grew up in the church for the convocation of a general council, in which the true sense of the church upon the controversies which had been raised might be finally and decretorially settled. Another, and, to many, a still more pressing motive for desiring a council, was the wish to bring about the reform of the alleged abuses as well of the court of Rome as of the domestic discipline and government of local churches, to which the movement of the reformers was in part at least ascribed. But the measures for convoking a council were long delayed, owing partly, it has been alleged, to the intrigues of the party who were interested in the maintenance of those profitable abuses, and especially of the officials of the Roman court, including the cardinals, and even the popes themselves; but partly also to the jealousies, and even the actual conflicts, which took place between Charles V. and the king of France, whose joint action was absolutely indispensable to the success of any ecclesiastical assembly. It was not till the pontificate of Paul III. (1534—1549) that the design assumed a practical character. One of the great difficulties regarded the place of meeting. In these discussions, much time was lost; and without entering into detail, it will suffice to say that the assembly did not actually meet till December 13, 1545, when 4 archbishops, 22 bishops, 5 generals of orders, and the representatives of the emperor and the king of the Romans, assembled at Trent, a city of the Tyrol. The number of prelates afterwards increased. The pope was represented by three legates, who presided in his name—Cardinals del Monte, Cervino, and Pole. The first three sessions were devoted to preliminaries. It was not till the fourth session (April 1546) that the really important work of the council began. It was decided, after much disputation, that the doctrinal questions and the questions of reformation should both be proceeded with simultaneously. Accordingly, the discussions on both subjects were continued through the fourth, fifth, sixth, and seventh sessions, in all which matters of great moment were decided; when a division between the pope and the emperor, who, by the victory of Mühlberg, had become all-powerful in the empire, made the former desirous to transfer the council to some place beyond the reach of Charles's arbitrary dictation. The appearance of the plague at Trent furnished a ground for removal, and in the eighth session a decree was passed (March 11, 1547) transferring the council to Bologna.

This translation was opposed by the bishops who were in the imperial interest, and the division which ensued had the effect of suspending all practical action. Meanwhile, Paul III. died. Julius III., who had, as Cardinal del Monte, presided as legate in the council, took measures for its resumption at Trent, where it again assembled, May 1, 1551. The sessions 9—12, held partly at Bologna, partly at Trent, were spent in discussions regarding the suspension and removal; but in the 13th session the real work of the assembly was renewed, and was continued, slowly, but with great care, till the 16th session, when, on account of the apprehended insecurity of Trent, the passes of the Tyrol having fallen into the hands of Maurice of Saxony, the sittings were again suspended for two years.

But the suspension was destined to continue for no less than nine years. Julius III. died in 1555, and was followed rapidly to the grave by his successor (who had also been his fellow-legate in the Council as Cardinal Cervino), Marcellus II. The pontificate of Paul IV. (1555—1559) was a very troubled one, as well on account of internal difficulties as owing to the abdication of Charles V.; nor was it till the accession of Pius IV. (1559—1565) that the Fathers were again brought together to the number of 102, under the presidency of Cardinal Gonzaga, re-opening their deliberations with the 17th session. All the succeeding sessions were devoted to matters of the highest importance —communion under one kind; the sacrifice of the mass; the sacrament of orders, and the nature and origin of the grades of the hierarchy; marriage, and the many questions connected therewith. These grave discussions occupied the sessions 17—24, and lasted till November 11, 1563. Much anxiety was expressed on the part of many bishops to draw the council to a conclusion, in order that they might be enabled to return to their sees in a time so critical; and accordingly, as the preliminary discussions regarding most of the remaining questions had already taken place, decrees were prepared in special congregations comprising almost all the remaining subjects of controversy, as purgatory, invocation of saints, images, relics, and indulgences. Several other matters, rather of detail than of doctrinal principle, were referred to the pope, to be by him examined and arranged; and on the 3d and 4th of December 1563, these important decrees were finally read, approved, and subscribed by the members of the assembly, consisting of 4 cardinal legates, 2 other cardinals, 25 archbishops, 168 bishops, 7 abbots, 7 generals of orders, and 39 proxies of bishops—making in all 252.

These decrees were confirmed, January 10, 1564, by Pius IV., who had drawn up, based upon them in conjunction with the creeds previously in use, a profession of faith known under his name. See Roman Catholic Church. The doctrinal decrees of the council were received at once throughout the Western Church, a fact which it is necessary to note, as the question as to the reception of the decrees of doctrine has sometimes been confounded with that regarding the decrees of reformation or discipline. As to the latter, delays and reservations took place. The first country to receive the decrees of the council as a whole was the Republic of Venice. France accepted the disciplinary decrees only piecemeal and at intervals.

It would be out of place here to enter into the question as to the merits of this unquestionably great and momentous assembly, which may be said to have practically decided the religious destinies of the Western Church. It is viewed with directly opposite impressions by opposing critics, and it is commonly even said that in the Catholic Church itself the Council of Trent has met its worst adversary in the person of one of the priests of its own creed, the Servite monk, Fra Paolo Sarpi.

It must be confessed, however, that the most candid of modern inquirers have shewn that Sarpi cannot fairly be regarded as a Roman Catholic. His sympathies are all strongly anti-Roman, and there are abundant indications in his work of a rationalising tendency, which plainly ought to rank him among the partisans of that free inquiry which it has been the object of Trent to repress by judgment, pronounced once for all, and excluding all controversy. See SARPI. And although there are perhaps equal exceptions against the impartiality of his rival historian and antagonist, Pallavicino, the latter is admitted by Ranke, Raumer, and others to be far more reliable in the use of documents than his Servite adversary.

The canons and decrees of the Council of Trent were issued in Latin, and have been reprinted innumerable times. They have also been translated into almost every modern language; the most approved English translation being that of the Rev. Jeremiah O'Donovan. One of the supplementary works assigned to the pope by the council at its breaking up was the completion of a catechism for the use of parish priests and preachers. This work has not all the authority of the council, but it is of the very highest credit, and is extensively used, having, like the canons and decrees, been very generally translated. Another similar work was the publication of an authentic edition of the Vulgate version of the Bible, as well as of the Missal and Breviary. All these have been accomplished at intervals; and there is besides at Rome a permanent tribunal, a congregation of cardinals, styled Congregatio Interpres Concilii Tridentini, to which belongs the duty of dealing with all questions which arise as to the meaning, the authority, or the effect of the canons and decrees of this celebrated council. See SARPI, PIUS IV., PALLAVICINO.

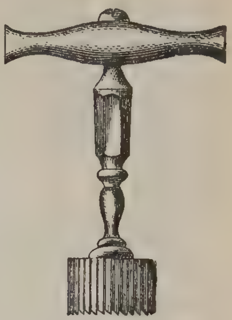
TRE'NTON, the capital city of New Jersey, U. S., on the left bank of the Delaware River, at the confluence of Assunpink Creek, and head of steam-navigation, 30 miles north-east of Philadelphia, and 57 south-west of New York; a well-built and handsome city, with a fine view of the river. It contains the state Capitol; state lunatic asylum, for 325 patients; state normal school; penitentiary, with 317 inmates; state library, of 8000 vols.; 22 churches; 5 newspapers; extensive railway connections; and manufactories of locomotives, machinery, cannon, rifles, wire, wire-cordage, crockery, terracotta, cotton, woollen, paper, &c. In the war of the Revolution, T. was the scene (December 25, 1776) of a night-attack by Washington upon the British troops, whom he surprised by crossing the Delaware, when the floating ice was supposed to have rendered it impassable. Pop. (1870) 22,874; (1880) 29,910.

TRENTON FALLS, a village of New York, U. S., on West Canada Creek, 15 miles north-west of Utica, celebrated for its beautiful cascades (6 in number), with an aggregate fall of 312 feet, in a deep ravine, 2 miles long, with walls of rock in places 150 feet high.

TREPA'N. See TREPHINE.

TREPA'NG. See BÊCHE-DE-MER.

TREPHI'NE AND TREPHINING. (The instrument in its original form was called a *trepan*, from Gr. *trupao*, allied to Lat. *tereo*, to bore; the now usual form is called a *trephine*.) The operation of trephining consists in the perforation of a bone by means of a trephine, which is a small cylindrical or circular saw, with a centre-pin on which it works. It is practised on the skull in cases of fracture: '1st, when a portion of the bone is depressed, and encroaches on the cavity of the skull, producing compression of the brain, and the fragment cannot otherwise be raised; 2dly, for punctured fractures by which the inner table is splintered, separated from the outer table, and lying loose on the dura mater; and 3dly, for effusion of blood, or of inflammatory products, between the bones and membranes, or between the latter and the brain, when it is presumed that the effused fluid may be evacuated by the opening.'—Holmes's *System of Surgery*, vol. iv. p. 1044. It has likewise been employed in epilepsy, with the view of removing an assumed local cause of disturbance; but it is not likely to be ever again used in that disease, as it is now an established axiom, that as the operation itself may destroy life, its application is not justifiable, except as the last resource of surgery in extreme cases.



Trephine.

Attempts have been made by various surgical-instrument makers to regulate the action of the trephine by means of a movable collar, so as to prevent the brain from being injured after the skull has been perforated. For the method of applying the instrument, we may refer to any work on Operative Surgery.

TRE'SPASS as a legal term, in the Law of England, means any wrong or injury committed upon either the person or property of an individual, not amounting to a crime. As regards a trespass to the person, the more familiar term is an assault or imprisonment; but trespass as to goods and chattels is more commonly known under the names of the remedies applied, as, for example, actions of Trover (q. v.), Detinue (q. v.). Trespass is the technical as well as popular name for that kind of injury which is done to a man's land or house by intruding into it against his will. In English law, the maxim is well known, that every man's house is his castle, and he is entitled to treat as an enemy any person who attempts to enter without his leave. There are, however, a few exceptions to this rule of the inviolability of a man's house, for it is no protection against the officers of the law when executing criminal process—for example, coming to apprehend a person charged with crime. But, as regards mere civil warrants, the officers of the law have no right to break open a man's outer door in order to effect an arrest for debt; and no civil court can give the bailiff such a power. The consequence is, that the bailiff can only wait outside, or endeavour by some stratagem to get inside the house in a peaceable manner; and if once inside the outer door, he can then break his way through the house, in order to find his debtor. Such is the law as to intruding into a man's house armed with the authority of the law.

It is a general rule applicable to a man's house as well as land, that if a stranger enter without leave, and do not quit at the request of the owner (who is not bound to state any reason for his request), the owner may by force eject the intruder. In doing so, however, he must not use more force than is necessary to overcome the resistance offered. If the intruder enter with force, the owner may turn him out without even first requesting him to depart; but if the intruder enter quietly, he must first be requested to leave before hands can be put upon him. If, in turning a stranger out, the stranger assault the owner, then the latter may defend

himself; but a policeman cannot interfere, or rather it is not compulsory upon him to interfere, unless he sees an assault committed by the intruder. Sometimes it is erroneously believed that a person is entitled to go to another's house on lawful business, and insist on admission, and even to remain till he get an answer—such as a creditor to demand his money; but this is not so. A creditor may be ordered away, and has no more right to intrude than any stranger. It is also sometimes erroneously supposed that any member of the public is entitled to enter into certain public places, such as a shop or a theatre; but this is not so. Any shopkeeper can turn any person he pleases, at any moment, out of his shop, and is not bound to deal with any person except he chooses. So with a keeper of a theatre or other place commonly described as public places. There is an exception, however, as to an Innkeeper (q. v.), who is bound, if he have accommodation and the means, to admit a traveller requiring refreshment. As to all other places, the general rule is, that whoever is the occupier of a house, or of land, is exclusively entitled to possession, and can extrude any person who refuses on request to leave; or if he prefer to resort to his legal remedy, he can sue such intruder in an action of damages. The amount of damages recovered will depend greatly on the circumstances attending the trespass, and whether insult or outrage was an accompaniment.

It is often erroneously believed by the public, as well as by some landlords or occupiers, and it is probably a wholesome delusion, that it is a criminal offence for a stranger to trespass upon lands, and that such stranger can be given into custody for doing so; and to keep up this impression, it is common for landlords or occupiers to stick up a notice with the words: 'Trespassers will be prosecuted.' But the fact of such a notice, or of there being a fence to the land, does not make any difference with regard to the trespasser, who is just as much liable to an action of damages, but to nothing else, for the trespass, whether he knew or not of such notice; and in neither case can he be given into custody, as if for a criminal offence. If, however, a trespasser were to break the trees, or do wilful damage (other than mere walking or riding) he may be liable to be apprehended; and if he is at the time trespassing with intent to catch or kill game, he may in some cases be apprehended and given into custody. See GAME, POACHING. It is a defect in the law that owners of land have no summary remedy except physical force to turn out or keep off trespassers, and that justices of the peace have no power to impose a moderate fine upon trespassers for repeating acts of trespass after notice that the owner or occupier dislikes them.

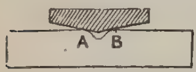
Not only human beings are trespassers, but the word is also by analogy applied to the trespasses of dogs, cats, and other animals. The trespasses of cattle are often of importance, in consequence of the damage done by them. The rule of law which governs the rights of occupiers of land on that subject is the following. An owner is not bound to fence his land, and whether fenced or unfenced, a neighbour is bound neither to trespass himself nor allow his cattle to trespass. If, therefore, A's cattle trespass on B's land, B can impound them; that is, he can lock them up, and keep possession till the owner pay for the damage done; or, if he prefer it, he can bring an action to recover the damages; or, he may drive them off, and also bring the action, until by one or or other remedy he is satisfied. With regard to dogs, cats, and similar domesticated animals, the rule is, that the owner is merely responsible for such mischief as they commit by reason of some negligence on his part. If, for example, he knows of some bad propensity they have to stray and attack or damage third persons, then it becomes his duty to take such means as will prevent their doing the mischief; but he cannot be held responsible unless and until the animals have on a former occasion done the mischief—in other words, it is only for a second and not a first offence that he can be made liable. There is one exception only to this rule, recently created by statute, viz., where dogs trespass and worry sheep; in that case, by a recent change made in the law of the United Kingdom, the owner of the dog is to pay for the damage, though he was not aware of any propensity in the dog to do such mischief.

In order to guard against trespass both of men and animals, the owners of land have sometimes resorted to spring-guns and man-traps, planted in their grounds. This practice was carried to a great height in England, as well as Scotland, about forty years ago. It was decided by the courts in England that there was nothing to prevent an owner from so protecting his land; but to put a limit to it, a statute was passed which restricted such right to dwelling-houses and gardens; so that now in England, it is illegal to place man-traps and spring-guns in open fields. As regards, however, traps to catch dogs, cats, or other animals, an owner of land is entitled to place these in his lands, and even to allure the animals with bait, so as to invite them to their doom; but this must not be done so close to a highway as to tempt a dog aside which is lawfully passing along the highway, for the owner of a dog being entitled to the use of the highway for the dog as well as himself, is entitled to have no danger placed in its way, such as a strong-smelling bait, which should operate irresistibly on its animal instincts. It is, therefore, only in the open fields or woods not adjoining the highway, that these dog or cat traps can be lawfully placed for protection of game or otherwise.—In Scotland, the law is substantially the same as regards trespass as it is in England or Ireland; but it was held illegal at common law in Scotland to put man-traps in lands by way of protection: and it is still illegal to do so. In Scotland, also, there is a more summary remedy against trespassers than exists in England, for an interdict may be obtained to prevent mere trespassers, irrespective of the game or fishery laws; and even justices of the peace may deal summarily with mere trespassers.

TRE′SSURE, in Heraldry, a subordinary, generally said to be half the breadth of the orle, and usually borne double, and flowered and counter-flowered with fleurs-de-lis. It forms part of the royal insignia of Scotland, which are: or, a lion rampant gules, armed and langued azure, within a double tressure flory counterflory of the second. The origin of the tressure in the arms of Scotland has been traced by the older heralds to the 9th c., when they relate that it was granted by Charlemagne to King Achaius of Scotland, in token of an ancient alliance between France and Scotland, and with the view of indicating that the French lilies would in time coming be a defence to the Scottish lion. Chalmers insinuates that these two monarchs were probably not aware of each other's existence; and, in point of fact, the double tressure is not known to have been borne earlier than the time of Alexander III., on whose seal it appears. The tressure is, however, held in great honour in Scottish heraldry, and Lyon King-of-Arms has not been permitted to grant it to any subject without a royal warrant; as a mark of especial favour, it has, however, occasionally been accorded by the sovereign to the representatives of important

families directly descended by a maternal ancestor from royalty, or who had deserved well of their king and country.

TREVELYAN EXPERIMENT (so called from the person who first carefully studied the phenomenon). When a block of iron or copper is considerably heated and laid on a block of cold lead, a sound of some intensity, and more or less musical, is often heard. Trevelyan, after many trials, adopted for the 'rocker,' as it is called, a form somewhat resembling a fire-shovel, with a thickish block of metal instead of the blade. This is poised delicately on the lead block, so as to bear with nearly equal pressure on two points separated by a groove; and the rounded end of the handle is also supported. The annexed fig. shews a section of the head of the rocker and of the lead block. The rocker being heated, suppose it poised so as to touch the lead at A only. It heats the lead at A, and therefore suddenly expands it near that point, since lead is a bad conductor of heat. Thus, the lead, as it were, swells up at A, and tilts the rocker over to B. There the same process takes place, and so on; and as the rocker thus moves alternately from A to B, the successive impacts, occurring at nearly equal intervals, form a musical sound. This can be altered at pleasure by loading the rocker, or by altering its moment of inertia. By proper care, almost any conducting body may be made thus to rock upon another, though, in the majority of combinations, the effect is very slight. The explanation of the phenomenon, as given above, is due to Faraday.



TRÈVES (Ger. *Trier*, Lat. *Augusta Trevirorum*), a town of Rhenish Prussia, with a population (1880) of 24,141, capital of the circle of the same name, lies on the right bank of the Moselle, in a lovely valley, between vine-covered hills, about 65 miles south-west of Coblenz. The river is here crossed by a bridge of 8 arches, 710 feet long, and 25 broad. T. is a decayed place, and covers an area large in proportion to its population, owing to the number and size of the open spaces where houses once stood. The cathedral of St Peter and St Helen is a very interesting structure of various antiquity, principally of the early German Romanesque style of the 11th c., but retaining considerable remains in the interior of a previously existing Roman church of the age of Constantine. It has beautiful altars and tombs; rich old chasubles and missals; famous relics, among others the 'Holy Coat' (q. v.). Adjoining the cathedral is the *Liebfrauen-kirche*, a very graceful specimen of Early German Gothic architecture, finished in 1243. The only other ecclesiastical buildings of interest now remaining, are the chapel of the Benedictine convent of St Mathias outside the town, and the church of the Jesuits. T. contains some beautiful old dwelling-houses of Romanesque architecture. No place in Germany is so rich in remains of the Roman period. Among these are the *Porta Nigra*, a colossal gateway, probably one of the five gates by which T. was entered in Constantine's time, the so-called Roman baths (more probably part of an imperial palace), and a basilica built of Roman brick by Constantine for a court of justice, which, after being successively the residence of the Frankish kings and archbishops, was in a great measure demolished to make room for an electoral palace erected in 1614; this has recently been removed, and the basilica restored and fitted up as a Protestant church. Beyond the walls are the ruins of an amphitheatre. The piers of the already mentioned bridge, consisting of enormous blocks of lava, are also of the Roman period.

T. is the seat of a bishop, and of a provincial council, has a chamber of commerce, a priestly seminary, gymnasium, a library of 96,000 vols. and numerous MSS., a museum full of valuable antiquities—including the famous *Codex Aureus*, or MS. of the Gospels in gold letters, presented to the Abbey of St Maximin by Ada, sister of Charlemagne—and various benevolent institutions; and it carries on manufactures of woollens, cottons, and linens, besides a brisk trade in corn, timber, and Moselle wines.

T. derives its name from the *Treviri* or *Treveri*, a Gallic, or, more probably, a Belgic people, who inhabited, in Cæsar's time, a large tract of country between the Meuse and the Rhine. Their capital, *Augusta Trevirorum*, probably became a Roman colony in the time of Augustus, and ultimately became the head-quarters of the Roman commanders on the Rhine, and a frequent residence of the emperors, particularly of Constantine. Under the Franks, into whose hands it fell 463 A.D., it continued to flourish. In 843, it passed to Lorraine; in 870, to Germany; in 895, back to Lorraine; and finally was united to Germany by the Emperor Henry I. The Archbishop of T. was, in virtue of his office of Chancellor of Burgundy, one of the electors of the Empire, a right which seems to have originated in the 12th or 13th c., and continued till the French Revolution. The ambition and talents of some of these episcopal rulers obtained for them great political weight in Germany. Since 1814, T. has belonged to Prussia.—See Haupt, *T.'s Vergangenheit und Gegenwart* (2 vols., Trier, 1822); Steiniger, *Geschichte der Trevirer unter der Herrschaft der Römer* (Trier, 1845); and Braun, *T. und seine Alterthümer* (Trier, 1854).

TREVI'SO, a town of Venetia, capital of the province of the same name, on the river Sile, in a very fertile country, 17 miles north of Venice. It is the seat of a bishop, and has a handsome though still unfinished Duomo, with five cupolas, and having an altarpiece of the Annunciation by Titian; and among the other buildings are the old Gothic church of San Nicolo, with a number of excellent pictures, and the public library (30,000 vols.). The town is surrounded by a wall of from 24 to 38 feet in height, and strengthened by numerous bastions. Manufactures of hardware are carried on; there are also a sugar-refinery, a bell-foundry, and a number of paper-mills. Population, 20,000.

TREVOR, SIR JOHN, Knight, born in 1633. In the parliament of James II. which met on 19th May 1685, he was elected Speaker of the House of Commons. 'Trevor,' says Macaulay, 'had been bred half a pettifogger, and half a gambler, had brought to political life sentiments and principles worthy of both his callings, had become a parasite of the Chief Justice' (Jeffreys), 'and could on occasion imitate not unsuccessfully the vituperative style of his patron. The minion of Jeffreys was, as might have been expected, preferred by James, was proposed by Middleton, and was chosen without opposition.'—*History of England*, vol. i. p. 508 (ed. 1849). In the same year, he was made Master of the Rolls. He contrived to maintain his political and judicial position after the revolution of 1688, and was again elected Speaker on the meeting of parliament on 20th March 1690, on an understanding with the government that he was to take the management of what may fairly be called the bribery department. At the same time, he acted as first commissioner of the Court of Chancery, in which

position his integrity seems from the first to have been greatly suspected; and though he was deficient neither in learning nor in parts, his judgments were both long in being given, and contemptible when they were pronounced. For some years, he maintained both his power and position; but his greed and venality at length became so notorious that respectable gentlemen of all shades of political opinion were ashamed to see him in the chair. In March 1695, a Committee of the House of Commons was appointed to investigate into the truth of certain charges of bribery brought against their Speaker. Within a week, the Committee reported, that in the preceding session, Sir John T. had received 1000 guineas from the city of London for expediting a local bill. As soon as the report had been read in the House, it was moved that the Speaker had been guilty of a high crime and misdemeanour. He had himself to stand up and put the question. There was a loud cry of 'Aye.' He called on the 'Noes.' Scarcely a voice was heard. He was forced to declare that the 'Ayes' had it. Even his 'callous heart and brazen forehead' were unable to stand the unspeakable ignominy of his position. Had he returned to the House on the following day, he would have had to put the question on a motion for his own expulsion; he pleaded illness, and shut himself up in his bedroom. A few days afterwards, he was formally expelled. He still, however, retained the Mastership of the Rolls, 'to the great encouragement,' says North, 'of prudent bribery for ever after.' 'His profligacy and insolence united,' says Macaulay, 'had been too much even for the angelic temper of Tillotson, who had been heard to mutter something about a knave as the Speaker passed him.' There are anecdotes of him in Noble's continuation of Granger's *Biographical History*, vol. i. p. 172. He died 20th May 1717, and was buried in the Rolls' Chapel.

TRI'ADS (in Chemistry). Until recently, the terms *equivalent number* and *atomic weight* were usually regarded by chemists as synonymous. Many recent writers, amongst whom Laurent (see his *Chemical Method*, translated by the Cavendish Society) stands pre-eminent, have, however, shewn that there is an essential difference between them; and this difference is fully recognised by Professor Miller, who, in the latest edition of his *Chemical Physics*, 1863, thus defines it: 'The equivalent or combining proportion is an experimental constant which is independent of theoretical considerations; but the relative atomic weight is necessarily a matter of inference, and may be a number, often a multiple of the equivalent, and selected by the chemist from theoretical considerations, which, being based partly upon the law of gaseous volumes, partly on chemical grounds, partly on the phenomena of specific heat, seem to require that the atomic weights of a large number of the elements, if compared with the atomic weight of hydrogen, should be double of those commonly given.'—P. 22. Most chemists of the modern school now agree in arranging the elementary bodies in four groups; namely, 1. *Monad* or *Uniequivalent* Elements (or *Monads*), one atom of which in combination is equivalent to H_1, or one atom of hydrogen. In these, the atomic and equivalent numbers are identical. They are twelve in number, and include hydrogen, chlorine, bromine, iodine, silver, &c. 2. *Dyad*, or *Biequivalent* Elements (or *Dyads*), each atom of which, in combining with other bodies, is equivalent to H_2, or two atoms of hydrogen. In these, the atomic number is double the equivalent number. This group embraces twenty-five elements, including oxygen, sulphur, selenium, iron, zinc, &c. 3 *Triad* or *Terequivalent* Equivalents (or *Triads*), each atom of which, in combining with other bodies, is equivalent to H_3, or three atoms of hydrogen. In this group, which embraces nine elements, including nitrogen, phosphorus, arsenic, &c., the atomic and equivalent numbers are regarded as identical, except in the case of aluminum and rhodium, when the atomic number is doubled. 4. *Tetrad* or *Quadrequivalent* Elements (*Tetrads*), each of which, in combining with other bodies, represents H_4, or four atoms of hydrogen. Their atomic number is double the equivalent number They are eight in number, including carbon, silicon, tin, &c.

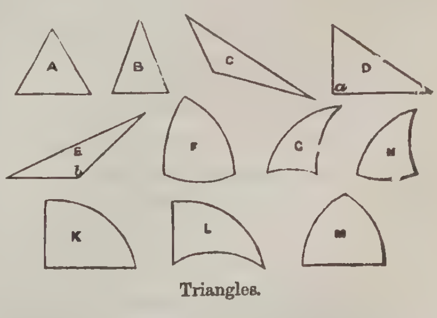
This arrangement of the chemical elements, which is being adopted in all the most recent text-books, has led to the insertion of what are termed *dashed symbols*, in which the number of dashes which are attached to the symbol for the atom of an element indicates its equivalency or interchangeable value for hydrogen. Thus, Ag is marked with a single dash, to show that silver is a monad, or, in other words, that the atom of silver may be substituted for an atom of hydrogen, so as to combine with an atom of chlorine, the resulting compound being $Ag'Cl$ (chloride of silver); Cu is marked with two, Bi with three, and Si with four dashes, to indicate that they are dyads, triads, and tetrads respectively, or that the atoms of copper, bismuth, and silicon may be substituted for two, three, and four atoms respectively of hydrogen, so as to combine with two, three, and four atoms of chlorine, forming $Cu''Cl_2$ (chloride of copper), $Bi'''Cl_3$ (chloride of bismuth), and $Si''''\ Cl_4$, or $Si^{(iv)}Cl_4$ (chloride of silicon). The terms mono-, di-, tri-, and tetratomic are also employed.

TRIAL, as a Legal term, applies most frequently to trial by Jury (q.v.), whether in a civil or criminal matter. See PROSECUTOR.

TRIAL AT BAR is a jury trial which takes place before the full court of four judges, instead of one judge only. It is seldom resorted to, and leave must be given in each case on special grounds.

TRI'ANGLE (*tres*, three, *angulus*, a corner), the most simple of geometrical figures, is a figure having three angles; but, oddly enough, it is generally defined by geometers as a figure of three sides, and its property of being three-angled is put in the subordinate position of a necessary consequence. It may be that this arises from Euclid's use of the word *tripleuron* (three-sided) in the definitions *prefixed* to his *Elements*; while *trigōnon* (three-angled) is employed in the work itself.

In plane geometry, a triangle is bounded by three straight lines; and triangles are classed according to the relative length of their sides, into *equilateral* (A),



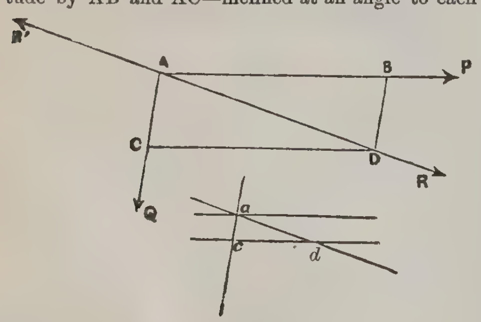
Triangles.

or equal-sided; *isosceles* (B), or having two sides equal; and *scalene* (C), or unequal-sided, the equality or inequality of the sides carrying with it the equality or similar inequality (of *greater* or *less*) of the angles respectively opposite to these sides, though the *ratio* of inequality of the sides by no means corre-

sponds to that of the angles. Considered with reference to the size of its angles, a triangle is *right-angled* (D) when one of its angles (a) is a right angle (90°); *obtuse-angled* (E), when it has one angle (b) greater than a right angle; and *acute-angled* (A or B), when it has no angle so great as a right angle; the well-known property, that the sum of the angles of a triangle is equal to two right angles, preventing the possibility of more than one of them being as great as a right angle. For the relations between the sides and angles of a triangle, see TRIGONOMETRY. The triangle being the fundamental figure of plane geometry, through which the properties of all other figures have been arrived at, the investigation of its properties has always been held to be of primary importance. Of the immense number of results obtained by investigation, we can notice only two or three in this place. The lines joining the angles of a triangle with the points of bisection of the opposite sides, intersect at the same point, as also do the perpendiculars from the angles on the opposite sides, the lines bisecting the angles, and the perpendiculars from the middle points of the sides. The point of intersection of the first series of lines is the centre of gravity of the triangle; those of the third and fourth series are the centres of two circles, the former of which touches the sides internally, and the latter passes through its three angular points. Another remarkable property of triangles, known as Napoleon's problem, is as follows: if on any triangle three equilateral triangles be described, and the centres of gravity of these three be joined, the triangle thus formed is equilateral, and has its centre of gravity coincident with that of the original triangle. See also TRIGONOMETRY and HYPOTHENUSE. The area of a triangle is half of that of a parallelogram which has the same base and altitude, and is thus equal to half the product of the base into the altitude; it may also be expressed by the formula $\sqrt{S(S-a)(S-b)(S-c)}$, where a, b, c, are the lengths of the sides, and S is half their sum.

In the geometry of the sphere, a triangle is a figure bounded by three arcs of circles (as F, G, H, K, L, and M).

TRIANGLE OF FORCES, in Mechanics, is the name given to a proposition which is merely a formal modification of the *Parallelogram of Forces* (q. v.), and as generally stated, is its converse. The parallelogram of forces enunciates that, if two forces, P and Q (fig.)—represented in direction and magnitude by AB and AC—inclined at an angle to each



other, act on a point A, their resultant, R, is represented in direction and magnitude by the diagonal, AD, of the parallelogram formed on the two lines AB and AC. Now, as the resultant, R, is equivalent to the combined action of P and Q, it would exactly counterbalance them if acting in the opposite direction AR′, but would still be fully represented by the diagonal line AD, taken as from D to A. Also, instead of AB, CD may be taken to represent P. Hence as the sides of the triangle ACD completely represent the three forces, we have the proposition, *that if three forces in the same plane be in equilibrium on a particle, and if in that plane any three mutually intersecting lines be drawn parallel to the directions of the forces, the lengths of the sides of the triangle thus formed will be proportional to the magnitudes of the forces.* Its proof rests upon the previously ascertained fact, that R′, P, and Q, three equilibrating forces at A, are proportional to AD, CD, AC, and on the geometrical theorem, that a triangle whose sides are respectively parallel to those of another triangle, has its sides proportional to those of the latter; and consequently, the ratio and relative direction of the forces R, P, and Q, are fully represented by *ad*, *cd*, and *ac*, the sides of the triangle *acd*. Again, as the sides of a triangle are to one another as the sines of the opposite angles, so also are the forces which the sides represent. Hence

P : Q : R′ : : CD : AC : AD
: : sin. CAD : sin. ADC : sin. ACD

(and substituting the sines of the supplementary angles) : : sin. QAR′ : sin. PAR′ : sin. PAQ; that is, each force is proportional to the sine of the angle between the directions of the other two.

TRIA′NGULAR NUMBERS. See FIGURATE NUMBERS.

TRIANGULA′TION is the operation of dividing any portion of the earth's surface into triangles of as large a size as possible, which may be called primary, and which must be afterwards subdivided into triangles of a smaller size, forming a great network of secondary or subsidiary triangles, which serve as a means of working down from great to less, and finally completing, by a system of scientific checks, an accurate map or delineation of the region covered by such triangles, forming the geodesical process called a trigonometrical survey. See TRIGONOMETRICAL SURVEY, ORDNANCE SURVEY. The same operation is used in the measurement of an arc of the meridian, for the purpose of ascertaining the length of a degree of latitude or longitude on any part of the earth's surface; but in this case, only primary triangles are necessary, as no topographical detail is required, and the positions of the apexes of the triangles are astronomically fixed in the most careful manner, which is not always done in the triangles of a trigonometrical survey.

In carrying out a system of triangulation, much judgment and an accurate local knowledge of a country are necessary; and it very often happens that a more extensive range of angles can be obtained from a comparatively low station, than from the tops of the highest mountains. The angles of each triangle should be as near equal as possible, and unless local circumstances render it unavoidable, very acute or obtuse angles should not be used. The sides of the primary triangles should be as long as can be conveniently observed, but in practice they vary from 80* miles or more to 4 miles, or even less. The angles are generally determined by a large theodolite, of as simple and strong a construction as possible, which is fixed on the most elevated points of mountain-ranges, &c. When the apexes of the triangles are very distant, heliostats, or mirrors reflecting the sun's rays, are often used, and in dark or cloudy weather the Drummond light has been employed. The primary triangles being fixed on the spherical surface of the earth, certain formulæ, according to the rules of spherical trigonometry,

* In the survey of India, and also in the process of connecting the triangulation of Ireland with that of Great Britain, many of the sides of the triangles greatly exceed this length.

must be applied to reduce them to the simple calculations for ascertaining, from certain known data, the sides and angles of plane triangles. The whole of those calculations are dependent on the accurate measurement of a base or fundamental line. The instruments invented by Captain Drummond, R.E., with which he measured the base line of the Irish survey at Lough Foyle, and which were afterwards employed by Sir T. Maclear in verifying Lacaille's base-line on the plains of Malmesbury, in the Cape triangulation, appear to have been as nearly perfect as possible. The length of base-lines used in modern surveys varies from 3 to 7 miles; General Roy's original base-line of the English survey was 5·19 miles.

At the end of a large triangulation, a second or testing base-line is always measured at a distance from the original one; if the measured length of this agrees with that ascertained by calculation, it may be considered a proof of the accuracy of the work in general. In the survey of Great Britain by Mudge and Colby, bases of verification were measured for at least every 200 miles, except in Scotland, where only one was measured near Aberdeen.

The triangles of the English survey have been extended to and connected with those of France, Russia, &c., as far east as Siberia, and south to Algeria; and it is not at all improbable that the triangles of the Russian survey will eventually be connected at one side with those of the great survey of India, which already has the apexes of many of its triangles on the summits of the Tibetan Himalaya, and to the eastward across Behring's Strait, with those of British America and the United States.—See Yolland's *Account of the Measurement of the Base of Lough Foyle* (Lond., Longmans, 1847); Colonel Portlock's *Life of Colby;* and art. 'Celestial Measurings and Weighings,' by Sir John Herschel, *Good Words* (1864).

TRI'AS, the oldest group of the Secondary strata, formerly associated with the Permian rocks under the name of the New Red Sandstone (q. v.). The term Trias, or the Triple Group, has been given to these beds by German geologists because they are separable into three distinct formations: the Keuper, Muschelkalk, and Bunter-sandstein; and the name has been generally adopted, as the beds are more fully developed in Germany than in England or France.

The typical beds are divided into—1. Keuper (q. v.), with a maximum thickness of 1000 feet; 2. Muschelkalk (q. v.), with a maximum thickness of 600 feet; 3. Bunter Sandstein (q. v.), with a maximum thickness of 1500 feet.

In England, the principal Triassic deposit occurs in a great basin of the palæozoic strata in Lancashire, Cheshire, Shropshire, Staffordshire, and Leicestershire. The eastern base of the great central Pennine range of hills is composed of Triassic beds, which, beginning in Leicestershire, run northwards through Nottingham and York to the coast of Durham. From Staffordshire, another series of these beds may be traced along the valley of the Severn, and crossing the Bristol Channel, through Somerset and Devon, to the southern coast.

Triassic beds extend from Massachusetts to South Carolina, and abound in China, India, Australia, &c.

TRIBE (Lat. *tribus*, a division, originally perhaps a third part, in reference to the three cantons whose coalescence formed the germ of Rome, q. v.), an aggregate of stocks—a stock being an aggregate of persons considered to be kindred—or an aggregate of families, forming a community usually under the government of a chief. The chief is possessed of despotic power over the members of the tribe. It is commonly said that he has 'patriarchal' power—such power, that is, as fathers in early times exercised over their children. The tribe has been the earliest form of the community among all the races of men.

In a very large proportion of existing tribes, the tribe is an aggregate of several stocks or distinct bodies of kindred. The persons of whom the tribe consists are included in stocks which are, or are accounted, distinct from each other. This organisation is sustained by two tribal customs—(1) persons of the same stock are forbidden to intermarry; and (2) kinship is reckoned through females only, so that children are accounted of the stock of their mother. Persons of the same stock, too, owe duties to each other, and are to some extent sharers in each other's liabilities. Thus, an injury done by a man is an injury done by his stock, which may be avenged upon any member of it; an injury done to a man is an injury done to his stock, for which every member of it is bound to seek vengeance. In consequence of the customs above mentioned, a husband must be of a different stock from his wife or wives; he must therefore be accounted of a different stock from his children; and when he has wives of different stocks, their respective children are accounted of different stocks. More than one stock is thus represented in every household; and since a man owes duties to his stock—the duties of acknowledged blood-relationship—while to those of his family who are not of his stock, nothing but the accident of birth (only accident) unites him, the family among these tribes has necessarily little cohesion. The tribal customs which have been referred to, ignore the family altogether; they are founded upon the idea of stock. They are the customs of people with whom the conception of stock was a powerful social influence, when that of the family was impotent—of people who must have been divided into stocks at a time when, possibly, they had *no* family system. It is inconceivable that such customs should have arisen in the face of a family system anything like that which prevails among civilised peoples, or even of such an approach to the family as many of those tribes now possess. And it follows that the family has *grown* among these tribes. It is obviously now growing among them. Now, in many cases, the only obstacle to its rapid development is the firm hold which the idea of stock has taken of the tribal life. On the other hand, the prevalence of customs founded upon the idea of stock proves a prior existence of stocks, or bodies of kindred. The separation into stocks must be older than the customs, at least as customs associated with the idea of stock. And keeping this in view, and considering how difficult it is to conceive of several stocks herding together at the early time when every stranger was an enemy, unless there was some natural connection between them—such a connection as the marriage-law and the system of kinship, when they arose, would establish—it may safely be concluded that each stock was originally a separate tribe. Into the tribe conceived of as a single stock, the marriage-law and system of kinship would gradually bring a variety of neighbouring stocks; and thus the tribe would become what it is—an aggregate of stocks. The progress of such tribes appears to have been from the tribe conceived of as a group of kindred to the tribe consisting of several stocks or groups of kindred; and now, though the family is not yet fully developed among them, they seem to be tending to become aggregates of families. The tribes of

Australasia are the most perfect examples of the organisation above described; but it also exists (or it existed) among the tribes of North, and most of those of South America, among a majority of the known tribes of Africa, and a large proportion of the ruder tribes of Asia.

Suppose male kinship (which must come with the growth of the family) introduced among tribes such as have been spoken of, containing different stocks. First, the stocks existing within the tribe would be fixed, stereotyped, within it; second, the growth of the family would be greatly promoted, and the influence of the idea of stock proportionately diminished. The family would in time rise to the importance originally possessed by the stock; and at length the tribe, still divided into stocks, would become, politically, an aggregate of families. The tribe would thus assume the exact shape which it had in the early ages of Greece and Italy, when it was an aggregate of families included in clans or bodies considered kindred (*gentes*); the exact shape which it now has among the most advanced of existing tribes. Since a tribe of the Australian type might thus develop into a tribe of the classical type, is it not probable that the latter really was the result of such a process of development? Regarded as a hypothesis, this view will be found to fulfil all the conditions of a good hypothesis. And if the circumstances of tribes which have what is popularly termed the marriage law of caste—among the greatest of which a division corresponding to the Roman *gens* prevails—can be reconciled with it, or with an extension of it, we shall have got a hypothesis capable of explaining the formation of tribes in general. The tribes above referred to, whether divided into clans or not, consider themselves of a common stock. They restrict marriage to the stock; but they always forbid marriages within certain degrees of relationship; and in numerous cases—among them, those of the most numerous caste peoples — they also forbid marriage within the clan or body considered peculiarly kindred. It will be convenient, for want of a better word, to speak of this marriage law as caste. And by caste tribes, in what follows, are to be understood tribes which have this marriage law.

Seeing that the law forbidding marriage within the tribe, and the law restricting marriage to the tribe, have both been widely prevalent among human races, both must be conventional, produced by circumstances; and if in their origin they are equally ancient, men, at the first, in respect of their circumstances, must long have been divided into two bodies very differently placed. This, however, is very improbable. There is no evidence for it; there is some evidence against it. The circumstances, too, capable of producing caste must have been isolating circumstances. The effect of an isolated position in producing an approach to caste may be seen in the case of the royal houses of Europe. Excepting, perhaps, mere physical isolation, it is difficult to conceive of isolating circumstances which could operate in the earliest times. Those which can be conceived of, and which are also known to have operated among caste peoples—the pride of conquerors, peculiarities of religion, the sentiment of an aristocracy or a priesthood, hereditary occupations—could only exist when society is somewhat advanced. It thus becomes highly probable that caste did not prevail in the earliest times—was not the original law of any tribes. There is strong corroboration of this in the fact, that it is found imperfectly established—in course of being established—among not a few existing tribes; and in the fact, that it became the law of peoples—for example, the Hebrews—whose ancestors, according to tradition, followed a different practice. In connection with these considerations, there is conclusive reason for holding that caste was not an original law, in the law of incest which prevails among the greatest of caste peoples, by which marriage is forbidden, not only within certain degrees of relationship, but also within the clan or body of kindred denoted by a family name. The existence of any law of incest among a caste people requires explanation. But how could a prohibition of marriage within the clan arise among people whose principle it was to marry within the kindred? This can only be referred to circumstances which preceded the origin of caste. Does it not, then, suggest the establishment, through the force of isolating circumstances, of caste—the restriction of marriage to the tribe, or to particular tribes—among tribes divided into stocks which had forbidden marriage within the stock? This would, at any rate, account for the facts. The original prohibition, upon this view, is still represented by the prohibition of marriage within the clan. But as tribes advanced, the family usurped the place of the stock; there sprung up a belief in the common origin of the tribe; and the law of succession to family property gave a new importance to near relationships. The law of incest would naturally tend to follow the practically important limits of relationship; and it might, being still applicable to the stock, be held specially binding within those limits; or it might be confined to them, for in the case of small and simply-constituted bodies, within which the differences of condition and of employment were few and slight, the stocks—pressed, on the one hand, by the growth of the family, on the other, by the growing belief in the common descent of the tribe—would be apt to disappear altogether. The absence of the stock or clan in the case of some of the smaller caste tribes, and the two laws of incest found among caste peoples—one of which, at least, seems otherwise inexplicable—can thus be accounted for consistently with the hypothesis of such peoples having progressed from the organisation of the Australian tribe. And it having been shewn that caste is not an original law, all other circumstances of caste tribes will be found consistent with that hypothesis. The belief which many tribes have had in their descent from one progenitor, is not corroborated in any case. It cannot prove its own truth. In many cases, it can be shewn to be a fiction; it is presumably so in all cases, and it does not afford an argument for or against any theory of the origin of tribes.

The hypothesis of development, as it may be called, is thus capable of connecting together all the varieties of the tribe, the simplest with the most advanced; and it gives us, as the earliest and simplest idea formed of the tribe, that it was a body of persons who conceived themselves to be of a common stock. It is in the favour of this hypothesis that it affords an easy and natural explanation of the peaceable political union and fusion into one people of neighbouring tribes; and of the fact, that a population is divided into a greater or less number of tribes, according as it is less or more advanced. Neighbouring tribes would contain the same stocks; they would thus be really homogeneous, and related; they would be ready for union as soon as their circumstances brought them into close contact, and made a political union desirable.

There are facts and arguments by which this hypothesis may be raised to so high a degree of probability, that its soundness can scarcely be doubted. A single example of them must suffice.

It is the received opinion that among the advanced tribes containing gentes, property was originally vested in the gens, and was only by slow degrees wrested from it by the family. It is involved in this, that at one time the gens was everything, the family nothing, in the organisation of the tribe; that the latter grew, and that as it grew, the former sunk in importance. The tribe, when property was exclusively vested in its gentes, must have been an aggregate of gentes, not an aggregate of families. All this is consistent with, and corroboratory of, the hypothesis of development; in particular, it strongly corroborates the view that the tribe at an early period consisted of several bodies of kindred, accounted distinct from each other, and each of which held property in common. It has never been accounted for upon any other view.

The only other theory which has been formed of the origin of tribes—commonly called the patriarchal theory—is, that a tribe consists in the main of the descendants of a single family, descent being chiefly, if not exclusively, reckoned through males; and that the gentes found within the tribe consist of the descendants of individual sons or grandsons of the common progenitor. It is evident that this theory does not explain the organisation of the numerous class of tribes first considered. It has been formed upon observation of the advanced tribes of the classical type, but it does not consist with the history of property (to test it at a single, but a vital point) even among them. It might account for property being vested in the tribe; it does not account for it being vested in the gentes. It can only do so by the aid of the assumption that, though the sons and grandsons of the original progenitor had the desire for family property, and divided his property, or accumulated property of their own, their descendants suddenly lost that desire, and began to hold in common. But such a supposition is too improbable to be entertained. This theory is also excluded in the case of all polyandrous peoples, for it assumes that society began with monandric marriage, a perfect idea of the family and male kinship—all conditions the very opposite of those which must at one time have prevailed among such peoples. And polyandry can be shewn to have prevailed so widely, that it is probable it has been the earliest practice of every human tribe. However this may be, a theory which is contradicted by a great proportion—much the greatest number—of the cases to be accounted for, and is in important respects not consistent with any class of cases, cannot be a good hypothesis; and therefore the patriarchal theory has no title to be accepted as explaining the normal history of the formation of tribes, or of any class of tribes. Its fundamental assumption, indeed—the segregation of individuals who became progenitors of tribes—seems to be at variance with the nature of man, which all experience has shewn to be social and gregarious, and to be the most averse to separate and independent action, when society is the least advanced. It should also be stated that it fails to do what a sound theory of tribal formation must do—to account for the fusion of neighbouring tribes, independently of conquest, into one people. To account for this, it has been customary to suppose that neighbouring tribes, wishing to unite, adopted one another; but there is no evidence of such adoption having ever been practised, and the supposition seems entirely improbable.

The patriarchal theory was, until recently, the received account of the formation of tribes. The theory which has here been styled the hypothesis of development was first propounded, though without elaboration, in a work published in 1865, *Primitive Marriage*, by J. F. M'Lennan.

TRIBONIA'NUS, a very eminent Roman jurist of the 6th c., of Macedonian parentage, but born in Pamphylia. He held, under the Emperor Justinian, the offices of quæstor, master of the imperial household, and consul. But he is famous chiefly through his labours in connection with the Code (q. v.) of Justinian (q. v.) and the Pandects (q. v.) T. died in 545.

TRI'BUNE. See ROME.

TRI'CHECUS. See MORSE.

TRICHI'ASIS (Gr. *thrix*, gen. *trichos*, of a hair) consists in a growing inwards of the eyelashes; three or four of them (sometimes only one) presenting their points towards the globe of the eye, while all the other hairs retain their natural position. The disease is exceedingly common among the lower classes, and especially the Irish. This affection causes great annoyance, by exciting a pricking sensation, and by the constantly irritable and watery state of the eye which it induces. The treatment consists in plucking out the offending hairs (if they are few in number) from time to time, each hair being removed by hair-forceps with a slow steady pull. If they form a little group, they must be removed by dissecting out the small portion of lid in which they are implanted, and uniting the wound with a suture. In other cases, it may be necessary to remove the entire margin of the lid.

TRI'CHINA SPIRA'LIS is the larva of a nematoid or thread-like parasitic worm recently recognised in its adult state. It was first detected as a pork-parasite by Professor Leidy of Philadelphia. In 1835, Mr Wormald, then Demonstrator of Anatomy at St Bartholomew's, gave to Professor Owen four microscopical specimens of speckled muscle from a subject that was then in the dissecting-rooms; and Mr Paget subsequently investigated the question. Professor Owen, to whom the discovery of the trichina is generally referred, soon afterwards communicated to the Zoological Society his 'Description of a Microscopic Entozoon infesting the Muscles of the Human Body,' in which he describes the speckles as capsules containing a spirally-coiled microscopic worm, to which he gave the generic name trichina (Gr. *thrix*, a hair), and the specific name *spiralis*, from its coiled arrangement. Mr Paget had independently arrived at similar results, with the aid of Robert Brown of the British Museum, and read a paper on the subject to the Abernethian Society a week before Professor Owen's memoir was read to the Zoological Society; so that his name should always be *at least* associated with that of Owen in reference to the discovery of this worm. From the date of this discovery to the present time, the *trichina* has been a fertile source of discussion. In 1845, the idea was mooted by various naturalists that the trichina was the undeveloped or sexless form of some other worm; and in 1855 (after the transformation of the cysticercus into the tapeworm was discovered), various suggestions were made on this subject; but it was not till 1860 that Virchow and Leuckart, by feeding animals on flesh containing trichinæ, arrived independently at the correct conclusion, that the parents of the encysted trichinæ are small nematoid worms, which had never previously been described, Leuckart's experiments being made with human flesh containing these parasites.

The young trichinæ, as they are seen in the human muscle, present the form of spirally-coiled worms, in the interior of small, globular, oval, or lemon-shaped cysts, which appear as minute specks

scarcely visible to the naked eye. These cysts are more or less covered externally with calcareous matter, according to the length of time they have remained in a fixed position, and the degree of degeneration which their walls have undergone. The trichina measures, according to Cobbold, on an average $\frac{1}{78}$th of an inch in length, and $\frac{1}{130}$th of an inch in breadth. The cysts are sometimes altogether absent, and hence they must be regarded as abnormal formations, resulting from local inflammation set up by the presence of the worm, which in this larval condition of existence measures $\frac{1}{25}$th of an inch in length, and $\frac{1}{630}$th of an inch in breadth. These larval worms exhibit a well-marked digestive apparatus, and afford evidence of the presence of reproductive organs, which are often sufficiently developed to enable the observer to determine the sex of the organism. The number of larval trichinæ that may simultaneously exist in the muscles of a single man or animal is enormous. In a cat on which Leuckart experimented, a single ounce of flesh was estimated to contain 325,000 trichinæ; and if all the voluntary muscles of a human body of ordinary size were similarly affected, the number of worms would exceed 1950 millions! Dr Cobbold believes that there can be no doubt that the number in a single 'bearer' (as he terms the sufferer) may *actually* amount to at least 20,000,000.

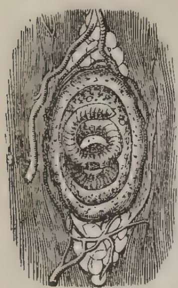


Fig. 1.

The worm lying coiled up in muscle, the outside of the cyst supporting fatty tissue, vessels, &c. (magnified).

We now proceed to the consideration of the mature worms. When an animal is fed with flesh containing the larval worm already described, and is killed a few days afterwards, a large number of minute worms are found mixed with the contents of the small intestines. On closer examination, they are found to be of two kinds—the larger and commoner one being the female, and the smaller and rarer one the male. At the second day after their introduction, these intestinal trichinæ attain their full sexual maturity; and in six days, the females contain perfectly developed and free embryos in their interior.

The female is a slender round worm, varying in length from $\frac{1}{12}$th to $\frac{1}{5}$th of an inch. The anterior end presents a bead-like appearance, from which the intestinal canal proceeds. The posterior three-fourths are mainly occupied by the reproductive organ, which is filled partly with free embryos, and partly with eggs in various stages of maturity. When these embryos have attained their full size within the uterus of the parent, they pass out at the genital aperture, and commence life on their own account. The accompanying diagram shews these embryos (highly magnified) in various stages of development. They are little worms with rounded ends, and presenting no indications of any internal organs. Before entering into the history of their migrations, we may mention that the male worm is seldom more than two-thirds the length of the female. It presents the same bead-like arrangements as the female, and a reproductive organ whose aperture apparently coincides with the anus; while the female sexual aperture is comparatively near the head-end of the worm. The body terminates with two hooks (of which only one is seen in the figure), which are doubtless subsidiary to the reproductive process. The males are less numerous and shorter lived than the females, and probably die after having discharged their natural function. The females continue bringing forth young for a period of two or three weeks. The embryos, according to Leuckart, Cobbold, and all our best helminthologists, penetrate the walls of the intestine, and pass directly into the muscles of their 'bearers' or 'hosts,' where, if the conditions are otherwise favourable, they are developed into the form originally observed by Owen and Paget. In this way, by proceeding along the course of the intermuscular connective tissue, some of them reach the muscles of the extremities and other distant parts; but the majority of the wandering embryos (according to Virchow) 'remain in those sheathed muscular groups which are nearest to the cavity of the body (abdomen and thorax), especially in those which are smaller and most supplied with connective tissue.' These embryos penetrate into the interior of the separate muscular bundles, and in the course of 14 days acquire the size and organisation of *Trichina spiralis*. The surrounding tissues soon become disorganised, and the spot inhabited by the coiled-up worm is converted into a spindle-shaped widening, within which the previously described cyst is formed by a hardening and calcification of the exterior. A point of great importance in relation to the distribution of this parasite, and as having a practical bearing upon the disease known as *Trichiniasis* (q. v.)

has been established by the experiments of Davaine —viz., that while in the adult condition, trichinæ perish in cold water in about an hour, and cannot survive the decease of their host for more than six hours, the larvæ remain alive in water for a month, and will live for a long time in flesh which has become putrid. In this way, 'a carcass near a marsh or rivulet may communicate the parasites to the ruminants that drink the water, or to pigs.'

In the same year (1860) in which Virchow and Leuckart proved, that by feeding an animal on flesh containing the *Trichina spiralis*, intestinal trichinæ were produced, and watched the transformation of the young of the latter into muscular trichinæ, a very important corroborative medical case was observed, and recorded by Zenker. In this case (which occurred in the Dresden Hospital in January 1860), the patient was a servant-girl, aged 20, and the principal symptoms were loss of appetite, prostration, violent pains and contraction of the limbs, and finally œdema, which, with a certain amount of pneumonia, terminated fatally in the course of a month. After death, numerous larval trichinæ were found in her muscles, while the intestinal canal contained sexually mature worms. The girl was taken ill on January 12; and three weeks previously, she had assisted in killing pigs and making sausages. It was further ascertained that, a few days before her illness commenced, she had eaten some of the meat in a raw state. On examination, it was found that the pork (both hams and sausages) contained numerous encysted trichinæ. It was, moreover, ascertained that the butcher and several members of the girl's family (to whom she had probably given sausages) were attacked with symptoms similar to those which, in her case, proved fatal. How the pig acquires its trichinæ is unknown. Beet-root, earthworms, moles, and rats have been suggested as their infectors; but on this subject see the advice given by the French commissioners in the next article. Nothing definite is known as to how widely trichinæ are diffused through the animal creation. The adult trichina is liable to infest the intestinal canal of all animals in which the larvæ have been found in the muscles. In this category must be placed man, the dog, cat, rabbit, rat, mouse, mole, hedgehog, and badger. Whether birds ever contain trichinæ is doubtful, and reptiles and fishes are quite free from this parasite.

TRICHINIASIS is the name of the diseased condition which is induced by the ingestion of food containing *Trichina spiralis* in large quantity. The first recorded case, as occurring in the human subject, is that of Zenker, which has been already noticed in the article TRICHINA; but there can be no doubt that the disease has long existed, although its origin was previously unsuspected.

The first symptoms of this disease, as it occurs in the human subject, are loss of appetite, followed by nausea and a sense of fatigue, prostration, and general indisposition. This stage lasts about a week. Pain and stiffness of the limbs, accompanied by swelling of the face, and fever of a peculiar type, characterised by a very frequent pulse, moderate thirst, and copious perspirations, now shew themselves; the commencement of the second stage of the disease being thus synchronous with the migration of the trichina-brood into the muscles. During this stage, pressure, or any attempt to move the parts under the control of the swollen muscles, is intensely painful, and even the normal respiratory movements cause such constant pain as to render sleep impossible. In severe cases, the patient lies on his back like a paralysed person. The tongue presents much the same appearance as in ordinary gastric fever. The bowels are most commonly constipated, but in some of the worst cases, there is continuous diarrhœa. The swelling which began in the face now disappears, and is replaced by swelling of the feet, which gradually rises to the trunk. In about the fourth week of the disease, the trichinæ may be regarded as permanently settled, and as having completed their destructive action on the muscles. This is the beginning of the third stage, which is mainly characterised by extreme weakness. The gastric symptoms abate, the appetite returns, and, in favourable cases, the muscular pains and swelling gradually diminish, while, in severe cases, this third stage is the most dangerous part of the disease; the diarrhœa being severe, and accompanied with tenesmus, and often with the involuntary discharges of the fæces and urine, while the skin exhibits extreme pallor, and is enormously distended with effused serum. Moreover, pneumonia often supervenes at this period. The fourth and last stage is that of convalescence. This may begin at the fifth week, or later, and may last from three weeks to as many months. In mild cases, it is impossible to draw a definite line between this and the preceding stage. Death may occur at any period. It has been observed as early as the 5th, and as late as the 42d day of the disease. A single trichinous pig, if its flesh is eaten without being previously submitted to such culinary processes as to destroy the vitality of the larval trichinæ, may establish a local epidemic of this disease. The most important of those epidemics have occurred in Germany, and are noticed by a German physician, Dr Thudichum, in 'The Seventh Report of the Medical Officer of the Privy Council,' 1865. Of these, the second or great epidemic at Hettstädt was the most severe. It commenced in the second half of October 1863, and affected 158 persons, of whom 28 died. All these persons were found to have been eating trichinous pork, either perfectly raw, or in the form of smoked or fried sausage, meat-balls, brawn, black-pudding, &c.

As soon as a case of suspected trichiniasis comes under the notice of the physician, attempts should be made to remove the mature worms from the intestine by active purgation. For this purpose, calomel, in scruple doses, is more serviceable than any other purgative. Two or three such doses should be given at intervals of 24 hours. No special directions can be given for the treatment of the fever. If there is any appetite, the diet should be light, and at the same time nourishing. Liebig's Extract of Meat has been found very serviceable in keeping up the strength. The most effectual remedy for the sleeplessness was found to be the cold wet sheet, in which the patient should be wrapped repeatedly during the day. The preparations of opium only aggravate the discomfort. The other symptoms must be treated by the ordinary rules of therapeutics.

Considering the gravity of this disease, it would be of the greatest importance to be able to decide, during its life, whether a pig were trichinous or not. On this point there is some difference of opinion; but Professors Delpech and Reynal, who were charged by the French government to report upon this disease, assert that 'the animal, while living, shews no signs of the presence of trichinæ, nor can they be detected in the meat with an ordinary lens, but a powerful microscope renders them at once visible.' In Hanover, out of 25,000 pigs, 11 were found trichinous; in Brunswick, 16 were affected out of 14,000; while in Blakenburg, 4 were diseased out of 700. The French commissioners assert that a temperature of 167° F. is sufficient to kill the parasites, and that meat thoroughly salted is also perfectly

safe; they advise that smoke-dried sausages, though probably safe, should be well boiled. They further attribute the spread of the disease among pigs to the fact that they are foul feeders, and will eat any offal, such as the dead bodies of rats and other animals, which are known to be liable to the disease. They recommend farmers to be very cautious in feeding their pigs to avoid giving them flesh without first boiling it; to destroy rats and small carnivorous animals, and never to leave human or other excrements in places where pigs can reach them. Finally, they advise all experimenters to burn trichinous flesh when their investigation is completed, and not to throw it away; for a fragment of it might possibly be eaten by a rat, the rat devoured by a pig, and the pig thus become the medium of the disease to man. This utter destruction of the parasites is a point on which Dr Cobbold has long insisted. In 1863, a trichinous pig from Valparaiso, killed on board a merchant-vessel on the high seas, caused the death of two of the crew; and in 1864, there was a slight trichinous epidemic at Cheektowaga, New York. Athough the trichina was discovered in England, and has been noticed in Scotland and Ireland, these countries and France have hitherto been free, not only from any epidemic outbreak, but from any recognised case * of the disease; nor, so far as we know, has any trichinous pig been as yet found in the above-named countries.

TRICHINO'POLY (more correctly, TRICHINAPALLI), the capital of a collectorate of British India of the same name, on the right bank of the Kaveri, 30 miles west of Tanjur. The fort, which includes the old town, stands on the rugged slope of a steep granite rock, 500 feet in height, which from some points resembles Edinburgh Castle. The walls of the fort, recently demolished, had a circuit of two miles, and this area is inhabited by a dense population, dwelling in low, closely-packed huts. The streets are tolerably regular, and are crowded at all hours of the day with multitudes of passengers, bullock-carts, and cattle. Beyond the walls is St John's Church, containing the tomb of Bishop Heber, who was buried here in 1826. The climate, during eight months of the year, is exceedingly hot, nevertheless T. is the head-quarters of the south division of the Madras army; there are several barracks, and the lines for the men and the officers' houses cover a space of ground six miles in circumference. Cheroots are manufactured here in large quantity, from excellent tobacco grown in the vicinity. Manufactures of hardware, cutlery, and jewellery, especially gold chains, harness, and saddlery, in all of which branches the natives of T. have long been famed, are extensively carried on. Pop. 30,000, exclusive of the garrison.

TRICHOCE'PHALUS (derived from the Gr. *thrix*, gen. *trichos*, a hair, and *cephale*, the head) is the name given to a genus of intestinal worms, of which one species, *T. dispar* (described by the older writers, who mistook its head for its tail, as *Trichuris* and *Ascaris trichiura*), infests the human intestinal canal. Dr Cobbold describes it as a small nematoid worm, the male measuring $1\frac{1}{2}$ inches, and the female fully 2 inches in length; it is characterised by an extremely long hair-like head and neck, occupying about two-thirds of the entire length of the body. This parasite is comparatively rare in this country, while, according to M. Davaine, not less than one-half the inhabitants of Paris are infested by it. Its presence is attended with little or no inconvenience. Its development and mode of gaining access into the body are subjects to which much attention has recently been paid, but which are by no means as yet cleared up. Davaine finds that the eggs are not developed within the host's intestines, but are discharged *per anum*, in the immature condition in which they escape from the parent; and it further appears, that after their expulsion, a period of six months must elapse before embryonic formation commences. As in the more common instance of *Ascaris lumbricoides*, it is probable that they complete their development in open water, from which they are transferred to the human stomach.

For further information on the genus *Trichocephalus* generally, we may refer the reader to Part I., chap. v. of Dr Cobbold's *Entozoa;* while the species considered in this article is fully discussed in Davaine's *Traité des Entozoaires.*

TRICHO'PTERA. See CADDICE.

TRICK, a term used in Heraldry to denote a mode of representing arms by sketching them in outline, and appending letters to express the tinctures, and sometimes numerals to indicate the repetition of changes.

TRICLI'NIUM, the apartment in a Roman house in which the meals were eaten.

TRI'COLOUR means literally no more than a flag in three colours, which is the case of almost every national ensign; but the applied sense limits it to flags having three colours in equal masses, and these are ordinarily assumed by nations which profess to have gained their 'liberty.' The present European tricolour ensigns are: France—blue, white, red—divided vertically. Italy—green, white, red—divided vertically. Belgium—black, yellow, red—divided vertically. Holland—red, white, blue—divided horizontally. The tricolour took its rise at the commencement of the French Revolution as the badge of the National Guard. The red and blue were selected as the arms of Paris, and the white was added, as the colour of the army, to shew the intimate union which should subsist between the people and the armed force.

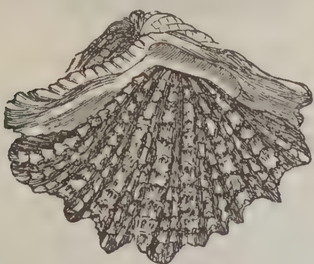
TRICOUPIS, SPIRIDION, a modern Greek statesman and author, son of a primate of Missolonghi, was born in that town in 1791. After completing his studies in France and England, he went to the Ionian Isles, where he aided Lord Guilford in the foundation of the university of Corfu (1820); but on the outbreak of the war of independence in the following year, he hastened to enrol himself among the patriots, and played an important part in the great struggle. From 1821, except during the presidence of Capo d'Istria, he was continually employed in administrative and diplomatic business. During the reign of King Otho, he was thrice sent to London (1835—1838, 1841—1843, and 1850—1855) as envoy-extraordinary; he was Minister of Foreign Affairs and of Public Instruction (1843); vice-president of the Senate (1844—1849); and envoy-extraordinary to Paris (1850) on the occasion of the blockade of the ports of Greece by England. In the grave political vicissitudes of late years, he has had his share, and in 1862 declined to form a ministry on account of ill health.

T. enjoys a great reputation in his own country as an orator and historian. His funeral oration on Lord Byron (whose friend and comrade he had been), delivered in the cathedral of Missolonghi, some days after the poet's death, has been translated into most European languages. Many other orations, partly religious and partly political, spoken

* In 1835, Mr Wood of Bristol published, in the *Medical Gazette*, a case of acute rheumatism, accompanied by pneumonia, in which trichinæ were discovered after death. No one can read the case without being struck by the idea that Wood *all but* anticipated Zenker in discovering a new disease.

by T. in the course of the revolution, have been collected and published (Paris, 1836). Besides these, we must mention a martial poem on the Klephts (*Poiēma Klephtikon*, Par. 1820); but his masterpiece is his History of the Greek Revolution (*Historia tes Hellēnikēs Epanastaseos*, Lond. 1853—1854), a work which is praised for its accuracy, impartiality, and style.—*Dictionnaire des Contemporains.*

TRIDA′CNIDÆ, a family of lamellibranchiate molluscs, having the shell open, the valves equal, the foot small, and furnished with a byssus. *Hippovus maculatus*, the BEAR'S-PAW CLAM (q. v.), is



Tridacna gigas.

prized for its beauty. *Tridacna gigas* is remarkable for its great size, exceeding that of any other bivalve. The shell of a single specimen has been known to weigh more than 500 lbs. The valves are sometimes used in Roman Catholic churches for holy-water vessels. They are also used as an ornament for grottoes and fountains. They are deeply furrowed and beautifully grooved. This great mollusc is a native of the East Indies, and is found in shallow water. It is used for food, and one suffices for a number of persons.

TRI′DENT, in Classic Mythology, is used as the symbol of Neptune's sovereignty over the sea. It consisted of a staff, armed at one end with three short prongs, with double barbs at the points, resembling the *fuscina* used by the Italians in catching large fish, particularly the sword-fish, from which we may perhaps infer that Neptunus was originally the god of fishermen. It was customary among the Grecian states to place the figures of their patron deities, or their appropriate symbols, on coins; hence, we frequently meet with the trident on ancient coins, such as those of Saguntum, &c.; likewise on the Sicilian coins of Hiero, &c.

TRIE′NNIAL PRESCRIPTION, in the Law of Scotland, is a limit of three years imposed on all creditors to bring their actions to recover a certain class of debts and damages—such as actions to recover merchants' accounts, servants' wages, house-rents (where the lease is verbal), debts due to tradesmen, lawyers, and doctors. So actions to recover damages for wrongous imprisonment must be brought within three years.

TRIË′ST, or **TRIË′STÉ** (Slav. *Tērst*), the most important seaport of the Austrian monarchy, and the most considerable trading town on the Adriatic, stands at the head of the Gulf of Triest, an arm of the Gulf of Venice, 90 miles south-west of Laibach, on the Vienna and Triest Railway. It is an imperial free town, and attached and belonging to it is a territory 46 sq. m. in extent, consisting of the slopes of the *Triestiner Karst*, which decline somewhat abruptly toward the Adriatic shore. The city of T., in which the population of the district is almost wholly massed, the other places being only small villages, consists of the old town, the new town, or Theresienstadt, and the two suburbs, Josefstadt and Franzenstadt. The old town, built on the slope of a steep hill, surmounted by a castle, forms about a fourth of the whole city, and is distinguished by its narrow streets and black walls. It contains the cathedral, an early Byzantine edifice of uncertain date, into the walls of which stones bearing Roman inscriptions and carving have been built, and the tower of which is said to rest on the foundation of a temple of Jupiter. The new town, with broad streets built in regular parallelograms and handsome houses, occupies the plain that fronts the sea. Between these two divisions runs the *Corso*, the chief thoroughfare of the city. The *Tergesteum*, in the new town, is a splendid modern edifice, built in 1842, and containing a bazaar, a grand concert and ball room, exchange and reading rooms, and the offices of the Austrian Lloyd's, the largest establishment in Europe for sea-steamers. To the north, on the sea-shore, is the new and magnificent Lazaretto, with a harbour in which 60 vessels can perform quarantine at once. There are numerous churches for Greeks, Jews, Roman Catholics, and Protestants. The population includes Germans, Americans, Italians, Greeks, Jews, Armenians, Dalmatians, &c.; but Italian is the prevailing language. T. is a free port; and the harbour, the entrance to which is uninterrupted by islands or sandbanks, is well protected. The manufactures carried on here are very extensive. There are upwards of 40 establishments for ship-building, 3 great soap-works, and 7 rope-works. Rosoglio, white lead, and leather are manufactured, and wax-bleaching is carried on. Over 15,000 merchantmen and coasting-vessels enter the port annually. The value of the imports is about £5,500,000; that of the exports, £4,500,000. Pop. of the city in 1869 was 70,274; of the city with the surrounding district in 1880, 144,437.

T., the ancient *Tergeste* or *Tergestum*, was of importance under the Romans, and first receives historical mention 51 B. C., when it was overrun and plundered by neighbouring tribes. It was much improved by Augustus; and, in 1382, finally passed into the hands of Austria. It owes its prosperity chiefly to the Emperor Charles VI., who constituted it a free port, and to Maria Theresa. Since the year 1816, T. has borne the tile of 'The most Loyal of Town.'

TRIFLE, a supper-dish at evening entertainments. It consists of two parts. The lower is usually made of sponge-cakes, ratafias, or macaroons, soaked in sherry or Madeira, and placed in the bottom of a proper glass-dish; over these is then poured a mixture of fine boiled custard and of cream, in equal parts; and sometimes another layer of the cakes is laid, well soaked in sherry. A whip, or syllabub, is then made with sugar, cream, white of egg, and sometimes a little white wine and brandy, the froth of which, as it is formed by the whisk, is removed, and placed over the soaked cakes, and forms the second part of light froth of the trifle. Almost every cook has some variation in the manufacture of this dish.

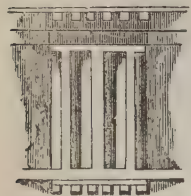
TRIFO′LIUM. See CLOVER.

TRIFO′RIUM, the arcade over the arches of a church between the central and side aisles. It is usually a dark gallery, being the wall-space against which the lean-to roof of the aisles rests. In the later styles, the side-aisles were covered with independent roofs, so as to allow the triforium arches to be filled with glass.

TRIGGER. See LOCK.

TRI′GLA. See GURNARD.

TRI'GLYPH, the ornament in the frieze of the Doric Style (q. v.). It is supposed to represent the ends of the beams in the original wooden temples. It is always divided into channels or flutes, with guttæ or drops below—see illustration.



Triglyph.

TRIGO'NIA, a genus of mollusca, represented at the present day by only three species, natives of Australia, but remarkably abundant in the Secondary rocks. Upwards of 100 species have been described from strata between the Trias and the Chalk inclusive, but not a single species is known from any Tertiary deposit. The shell is trigonal (whence the name), thick, and tuberculated, or ornamented with radiating or concentric ribs. The interior is nacreous. The external ligament is small and prominent, and the huge teeth are large, diverging, and transversely striated. The animal has a long, pointed, and powerful foot, with which it is able to make considerable leaps. The gills are ample, and united behind the body to each other and to the mantle.

TRIGONOCA'RPON, a common fruit in the Coal-measures, occurring in all the strata except the underclays and limestones. Some six or eight species have been established, which differ from each other in size and shape—some being as small as a pea, and others as large as a walnut. They are marked, when preserved in the round, with three longitudinal ridges, and from this character the name was derived. They have never been found attached to any plant. From their shape, and their occurring in such quantities in some localities that they might be gathered by the bushel, it was at first thought that they were palm-fruits; but Dr Hooker, from the examination of several specimens which exhibit structure, has shewn that they are not unlike the structure of *Salisburia*, a drupe-bearing coniferous tree, a native of China and Japan. He found that they were composed of four distinct integuments, and a large internal cavity filled with carbonate of lime, but which, he supposed, originally contained the albumen and embryo. The determination of the affinities of this fruit is the more important, as the existence of conifers in the Coal-measures was known from the occurrence in them of disc-bearing woody-tissue; and the absence of linear leaves and cones makes it the more likely that they belonged to the drupe-bearing division of the order. It is probable that the trunk, to which the generic name *Dadoxylon* has been given, and the casts of the large pith of which is known as *Sternbergia*, had for its leaves the fern-like fossils named *Noggerathia flabellata*, and *Trigonocarpon* for its fruit. Dr Dawson has, however, recently referred some *Trigonocarpa* to *Sigillaria*, and he considers the anomalous organism called *Antholites* to be the bud form of the fruit. He has never found them in contact with *Sigillaria*, and it is much more probable that this was a cryptogamous tree, and consequently had spores, and not seeds, for its fruit.

TRIGONOCE'PHALUS, a genus of extremely venomous serpents, of the family *Crotalidæ*, nearly allied to rattlesnakes, but having the tail terminated with a spine instead of a rattle. The head is covered with plates or shields; the dorsal scales are keeled. *T. rhodostoma* may be mentioned as an example. It is found in Java, and preys chiefly on frogs. *Cenchris*, *Craspedocephalus* and other genera have recently been separated from trigonocephalus. The Mokassin Snake of the southern United States belongs to the genus *Cenchris*. One of the most dangerous serpents of the West Indies is *Craspedocephalus lanceolatus*.

Trigonocephalus rhodostoma.

TRIGONOME'TRICAL SURVEY. Trigonometrical surveying is that higher branch of measurement of the earth's surface in which the use of angular instruments, such as the theodolite, altitude, and azimuth instrument or sextant, is indispensable in forming the network of triangles, on the accuracy of which the correctness of the survey depends. In the article TRIANGULATION, the necessary operations have been briefly adverted to, and in ORDNANCE SURVEY will be found a sketch of the history of the principal modern trigonometrical surveys executed, or now being made.

In the *Aide-Mémoire of Military Sciences*, conducted by officers of the corps of Royal Engineers, a very full and complete article will be found on this subject; and the government blue-books, from time to time issued on the surveys both of Great Britain and India, afford much valuable information on the internal economy and arrangements necessary for carrying on such vast works.

When it is necessary to fix the astronomical position of the stations, of course, the transit, zenith sector, and other instruments used in the observatory, must be transferred to situations very often difficult of access, exposed to strong winds, &c., which adds much to the difficulty of getting correct observations. Meteorological and magnetic observations are often taken simultaneously with the astronomical; and, indeed, are now considered as nearly indispensable in modern operations. See SURVEYING, TRIANGULATION, &c.

TRIGONO'METRY (Gr. *trigōnon*, a triangle, *metria*, measurement), the measurement of triangles. This definition, though expressing correctly enough the scope of trigonometry in its early stages, is now wholly inapplicable, as trigonometry, like geometry, has far exceeded its primitive limits; and though the original name is, for convenience, retained, the science may be more properly defined as the 'consideration of alternating or periodic magnitude.' Trigonometry, within the limits of its earlier definition, is geometrical; its advance beyond these limits is due to the introduction of purely algebraic methods. The quantities with which geometrical trigonometry has to deal are certain lines definitely placed with respect to an angle, and consequently varying with it. These lines generally denominated *trigonometrical functions* of the angle, are the sine, cosine, tanget, cotangent, secant and cosecant; and are represented in the accompanying figure. The angle BAC is placed at the centre of a circle, called the circle of reference; its *sine*, CD, is the perpendicular let fall from the extremity of one radius upon the other; the *cosine*, DA, is that part of the radius between the foot of the sine and the centre; the *tangent*, BE, is drawn

at right angles to one radius to meet the other produced; the *secant*, AE, is the radius produced to meet the extremity of the tangent; the *cotangent*, FG, is drawn from the extremity of a radius at right

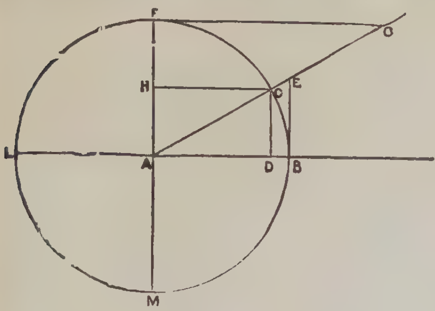


Fig. 1.

angles to one of the former, to meet the other produced; and the *cosecant*, AG, is the radius produced to meet the extremity of the cotangent. Other functions, as the *versed sine*, DB, which is the distance from B to the foot of the sine, and its counterpart, the *coversed sine*, FH, have been occasionally introduced and defined, but they are of no practical use. EAF, the angle which must be added to BAC to make up a right angle, is called the *complement* of BAC; and CAL, the defect of BAC from two right angles, is called its *supplement;* and by inspection of the figure, we can see at once that the sine of BAC, CD, is equal to AH, the cosine of its complement; that the cosine of BAC, AD, is equal to CH, the sine of its complement; and that generally any function of an angle is the co-function of its complement, and *vice versâ;* also, that CD, the sine of CAB, is also the sine of its supplement; AD, the cosine of CAB, is the cosine of its supplement; and that generally the function of an angle is the function of its supplement. If a right angle be added to BAC, then we have the triangles ADC, ABE, shifted so as to be situated in the same relative position to AF as they now are to AB, and each line is consequently at right angles to its former position; hence the sine of BAC is the cosine of (90° + BAC), and similarly of the others. By an extension of this process of investigation, we arrive at the general conclusions, that *if an angle be added to or taken from one or an odd number of right angles, the function of the original angle is the co-function of the one so derived;* and that *if an angle be added to or taken from an even number of right angles, the functions of the original angle are the functions of the derived one.* But since a function of an angle is the same function of its supplement, a knowledge of the function would not enable us to determine to which of the two angles it belonged, unless we possessed some knowledge of more than the mere magnitude of the function. This desideratum is supplied in the following manner: B is taken as the zero-point of reckoning, the radius BA, which is thus supposed to be fixed, is one of the bounding lines of every angle, the other side being supposed to move in the direction BFL, as the angle increases. Let the radius AC be supposed to sweep round the circle in a left-hand direction (viz., towards F), then, as it approaches F, the sine CD increases, till, on reaching F, the sine coincides with the radius; passing F, and moving towards L, the sine diminishes, till, on reaching L, it becomes zero. Continuing its progress round the circle, the angle BAC becomes *re-entrant* (viz., greater than two right angles); and its sine again increases, becoming equal to the radius at M, and diminishing in the fourth quadrant till it becomes zero at B. While the angle increased from B to L, the sine was drawn *downwards;* for the other half of the revolution, it was drawn *upwards;* hence, in the first and second quadrants, the sine is said to be *positive*, and in the third and fourth, *negative*, the position of a function in the first quadrant being adopted as the standard. The following table shews the variation (increase or decrease, and between what limits, as well as the sign affecting it) of each of the functions as the angle increases:

Angle.	Sine.	Cosine.	Tangent.	Secant.	Cotangent.	Cosecant.
0° to 90°	inc. 0 − R, +	dec. R − 0, +	inc. 0 − ∞, +	inc. R − ∞, +	dec. ∞ − 0, +	dec. ∞ − R, +
90° „ 180°	dec. R − 0, +	inc. 0 − R, −	dec. ∞ − 0, −	dec. ∞ − R, −	inc. 0 − ∞, −	inc. R − ∞, +
180° „ 270°	inc. 0 − R, −	dec. R − 0, −	inc. 0 − ∞, +	inc. R − ∞, −	dec. ∞ − 0, +	dec. ∞ − R, −
270° „ 360°	dec. R − 0, −	inc. 0 − R, +	dec. ∞ − 0, −	dec. ∞ − R, +	inc. 0 − ∞, −	inc. R − ∞, −

We here observe that all the functions increase and decrease alternately as the angle of which they are the functions passes from one quadrant to another; also that the sine and cosecant are affected by the same signs, as also are the cosine and secant, and tangent and cotangent.

Again, from fig. 1 we obtain, from the properties of right-angled and of similar triangles, the following relations between the functions: $\text{Sin.}^2 + \text{Cos.}^2 = \text{R}^2$, $\text{Tan.}^2 + \text{R}^2 = \text{Sec.}^2$, $\text{Cot.}^2 + \text{R}^2 = \text{Cosec.}^2$, Tan. : R : : Sin. : Cos., Sec. : R : : R : Cos., Cot. : R : : Cos : Sin., Cosec. : R : : R : Sin., and Cot. : R : : R : Tan. From these eight relations, we can easily obtain any one function in terms of any other, both as regards its magnitude and sign.

The reason why the circle and its radius are employed in the definition of the functions is, that we may obtain some invariable standard by which to estimate them, for while, as the angle increases from 0° to 360°, its functions are in a state of constant change, their standard of reference, the radius, remains the same. For greater simplification, the radius is taken as unity, and the relations become $\text{sin.}^2 + \text{cos.}^2 = 1$, $\text{tan.}^2 + 1 = \text{sec.}^2$, $\text{cot.}^2 + 1 = \text{cosec.}^2$, and (by the reduction from the proportional to the divisional form of the other five relations) $\text{tan.} = \frac{\text{sin.}}{\text{cos.}}$, $\text{sec.} = \frac{1}{\text{cos.}}$, $\text{cot.} = \frac{\text{cos.}}{\text{sin.}}$, $\text{cosec.} = \frac{1}{\text{sin.}}$, $\text{tan.} = \frac{1}{\text{cot.}}$; the various functions being expressed in terms of the assumed unit. Thus, in the right-angled triangle ABC (fig. 2), if AC be radius, BC = sin., and AB = cos., of the angle A; but if the radius be assumed as unity, $\text{sin. A} = \frac{\text{BC}}{\text{AC}}$, $\text{cos. A} = \frac{\text{AB}}{\text{AC}}$, and

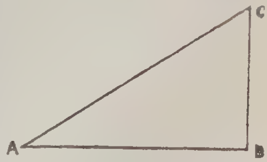

Fig. 2.

similarly from the above relations, $\text{tan.} = \frac{\text{BC}}{\text{AB}}$, $\text{sec.} = \frac{\text{AC}}{\text{AB}}$, $\text{cot.} = \frac{\text{AB}}{\text{BC}}$, and $\text{cosec.} = \frac{\text{AC}}{\text{BC}}$; and in algebraic trigonometry these latter are the definitions of the trigonometrical functions.

The only angular functions which geometry enables us to determine with accuracy are those belonging to the angles of an equilateral triangle (Euc. I. 1), an isosceles right-angled triangle (Euc. II. 9), and an isosceles triangle which has each of the angles at its base double of the third angle (i. e., base angles each 72°, vertical angle, 36°) (Euc. IV. 10); and from these, by means of a proposition (demonstrated in all text-books on the subject) which determines the functions of the angle $(A + B)$ from a knowledge of the functions of A and of those of B; and also, as a corollary to the preceding, the functions of 2A, 4A, 8A, &c., and inversely of $\frac{1}{2}A$, $\frac{1}{4}A$, &c., from a knowledge of those of the angle A, have been obtained and tabulated the functions of all angles from 1′ to 45°, the functions of angles from 45° to 360° being, as is evident from the above remarks respecting complementary and supplementary angles, merely repetitions of these.

The relations between the angles and sides of a triangle (fig. 3) are three in number, and are obtained from simple geometric considerations; they are—(1) $AB : AC :: \sin. C : \sin. B$; (2) $\cos. B = \frac{AB^2 + BC^2 - AC^2}{2 AB . BC}$; (3) $AB + AC : AB - AC :: \tan. \frac{1}{2}(B + C) : \tan. \frac{1}{2}(B - C)$. From these relations, in conjunction with the fact that the three angles of a triangle collectively amount to 180°, it is possible, having given any three (one being always a side) of the six elements (three sides and three angles) of a triangle, to determine the other three. It is this that constitutes trigonometry in its primitive and elementary form. If the triangles be right-angled, only the first relation, and the property of the sides of a right-angled triangle, are necessary for the complete solution. Further information on this subject will be found in any text-book.

Fig. 3.

Algebraic trigonometry is one of the most important branches of analysis, but is too extensive and varied to be even sketched here; suffice it to say, that in it the trigonometrical functions are not considered as geometrical magnitudes, but as numerical quantities having certain relations to each other, and that the circle as well as the angular functions are treated as multiples or sub-multiples of the radius. Many important results, such as the approximate estimation of the circumference of a circle, the completion of the solution of cubic equations, &c. have been obtained by its means; and a thorough knowledge of its modes and results is absolutely necessary to an acquaintance with higher mathematics.

Spherical trigonometry is plane trigonometry applied to spherical triangles. See any text-book.

TRI′KHALA, or TRIKALA, a town of European Turkey. 33 miles west-south-west of Larissa. It is built on the slope of a hill, manufactures cotton and woollen stuffs, and has a large transit-trade with Epirus and Albania. The neighbouring plains, which are watered by the Salembria (anc. *Peneus*), are rich in all sorts of fruits. Pop. about 10,000. T. is the *Trikka* of Homer, and was celebrated in the classic ages for its temple of Æsculapius.

TRILLIA′CEÆ, a small natural order of plants, belonging to the class Dictyogens (q. v.) of Lindley. They are herbaceous plants, with tubers or root-stocks, whorled leaves, hermaphrodite flowers; perianth of six leaves, the three inner leaves sometimes coloured; six, eight, or ten stamens, the filaments extending beyond the anthers in awl-shaped points; the ovary free, 3—5-celled, with numerous ovules; the fruit succulent. The order is characterised by narcotic properties. The genus *Paris* (q. v.) belongs to it.

TRI′LOBITES, an order of fossil crustacea entirely confined to the palæozoic rocks. They are specially abundant in the Silurian period, and disappear in the lower members of the coal-measures.

The body was covered with a chitinous shield, which consisted of a large united cephalic shield, a variable number of body segments, and a tail or pygidium, composed of a number of joints, more or less anchylosed. The eyes were sessile and compound. The lenses are frequently beautifully preserved, and in some species are so large that they can easily be seen with the naked eye. In *Asaphus caudatus*, each eye had at least 400 facets; and in the large *A. tyrannus*, it is estimated that there are no fewer than 6000. In some species, a bifurcated plate has been found in the region of the mouth, which is believed to be a labrum, but no antennæ or limbs have been yet detected in any specimen. They may have been entirely destitute of antennæ, as in some living animals to which they are nearly related these organs are very rudimentary; and their feet were probably soft and leaf-like appendages, bearing the gills, which would speedily perish, and leave no traces in a fossil condition. The sexes are believed to be indicated by variations in the length of the cephalic and caudal spines, and in the prominence of the head lobes. The members of the order varied greatly in size, some species being scarcely larger than a pin's head, while others, like *Asaphus gigas*, attained a length of 18 inches. It is probable that many named species may be only larval or transition forms of others. The minute *Agnosteus* is frequently found in such quantities as to indicate that it lived in shoals, as if it were the larval form of some large trilobite. Lockwood and Packard have shown that they resemble closely certain early immature stages of the *Limulus* of the American coast. Burmeister considers that trilobites have their nearest allies in the minute Phyllopoda, a section of entomostracous crustacea, which are continually swimming, at various depths, on their backs. He consequently supposes that trilobites lived gregariously in shallow water close to shore, moved only by swimming near the surface, and could not creep at the bottom; that they swam in an inverted position, with the belly upwards; that they made use of their power of rolling themselves into a ball as a defence against attacks from above; and that they lived on smaller water-animals.

Asaphus tuberculatus

Above 400 species have been described, and grouped into 50 genera. Of these, 46 are Silurian, 22 Devonian, and 4 Carboniferous.

TRI′LOGY, the name given by the Greeks to a group of three tragedies, either connected by a common subject, or each representing a distinct story. A satyric drama was customarily added as a termination, whence the whole was sometimes termed a *tetralogy*. Every tragic poet that wished to take part in a poetic contest had to produce a trilogy along with a satyric drama at the Dionysiac, Lenæan, and Anthesteriac festivals. We possess

only one perfect specimen of the classic trilogy,—the *Oresteia* of Æschylus, which embraces the *Agamemnon*, the *Chœphoræ*, and the *Eumenides*.—See Welcher, *Die Aeschylische Trilogie* (Darmst. 1824; Franz, *Des Aeschylos Oresteia* (Leip. 1846).

TRIMETHY′LAMINE, or TRIMETHYLIA $C_3H_9N = (CH_3)^3N$), is a very remarkable organic base, with an extremely powerful and disagreeably fishy odour. It is obtained as a colourless gas, readily soluble in water, and having a strong alkaline reaction. With acids, it readily forms soluble salts. It occurs in large quantity in the pickle in which herrings (especially their roes) have been lying, and in the spirit in which old anatomical preparations have been long suspended; and (strange as it may appear) it imparts to the leaves of *Chenopodium olidum* their atrocious odour, and to the flowers of *Cratægus oxyacantha* (the common hawthorn), their agreeable fragrance. It is obtained by distillation from ergot of rye, from guano, the juice of the leaves of red beet-root, and from putrid yeast, and has been detected in small quantity in human urine and in the blood of the calf. It may be formed artificially by the action of iodide of methyl on dimethylamine; but the source from which it may most readily be derived is herring-brine.

TRIMMER, a political term in use in the reigns of Charles II. and William III., originally applied to certain politicians of Charles's time, of whom the chief was Charles Montagu, Earl of Halifax, who held opinions half-way between the extreme Whigs and Tories. Halifax adopted the name Trimmer as a title of honour, maintaining that everything good was a medium between extremes.—The same term was applied more generally by Dryden and other writers of the same period to all who, professing to be friends to monarchy, were at the same time enemies to the Duke of York, and who were equally obnoxious to the court and to the fanatical republicans.

TRIMMER, MRS SARAH, was born at Ipswich on 6th January 1741. Her father was a Mr Joshua Kirby, a man of intelligence and piety, who removed to London about 14 years after, and became tutor to the Prince of Wales, afterwards George III., in the science of perspective, a subject in connection with which he was favourably known by several ingenious works. Among other distinguished persons with whom his daughter had now the advantage of meeting, was the great Dr Johnson, with whom she speedily became a favourite. In 1759, her father was appointed Clerk of the Works at Kew Palace, whither he went to reside; and here Miss Kirby became acquainted with Mr Trimmer, to whom, in 1762, she was married. It was not till the year 1780 that she came before the world as an authoress, by the publication of her *Easy Introduction to the Knowledge of Nature*, intended for the use of young people. The success of this little work encouraged her to further efforts in the same field; and during the next few years, she issued in succession six volumes of *Sacred History, selected from the Scriptures, with Annotations and Reflections adapted to the Comprehension of Young Persons.* Her next work was the *Economy of Charity*, addressed to benevolent people of her own sex, which went through several editions. She edited subsequently in succession *The Family Magazine*, and the *Guardian of Education;* a selection of her contributions to the first of which was issued under the title of *Instructive Tales;* her chief papers to the other being collected in the volume published after her death as *An Essay upon Christian Education.* Besides this, she laboured assiduously in the preparation of school-books for the Society for Promoting Christian Knowledge, intended to supersede the imperfect manuals then in use; and did much miscellaneous work of a somewhat cognate kind. She died quite suddenly on the 15th of December 1810. Her works for the young, though now for the most part superseded, were excellently adapted for their purpose, and for a long time had an extensive popularity.

TRIMÛRTI (from the Sanscrit *tri*, three, and *mûrti*, form) is the name of the Hindu triad, or the gods *Brahman* (masculine), *Vishn'u*, and *S'iva*, when thought of as an inseparable unity, though three in form. The *Padma-Purân'a* (see PURÂN'A), which, being a Purân'a of the Vaishn'ava sect, assigns to Vishn'u the highest rank in the T., defines its character in the following manner: 'In the beginning of creation, the great Vishn'u, desirous of creating the whole world, became threefold: creator, preserver, and destroyer. In order to create this world, the supreme spirit produced from the right side of his body himself as Brahman; then, in order to preserve the world, he produced from the left side of his body Vishn'u; and in order to destroy the world, he produced from the middle of his body the eternal S'iva. Some worship Brahman, others Vishn'u, others S'iva; but Vishn'u, one, yet threefold, creates, preserves, and destroys; therefore, let the pious make no difference between the three.' And the *Matsya-Purân'a*, where speaking of *Mahat*, or the intellectual principle of the Sânkhya philosophy (see SÂNKHYA), says that 'Mahat becomes distinctly known as *three* gods, through the influence of the three qualities, goodness, passion, and sin; being one person and three gods—viz., Brahman, Vishn'u, and S'iva.' Apart, therefore, from sectarian belief, which makes its own god the highest, and gives him the attributes also of the other gods, *Trimûrti* implies the unity of the three principles of creation, preservation, and destruction, and as such belongs more to the philosophical than to the popular belief. When represented, the T. is one body with three heads: in the middle, that of Brahman; at its right, that of Vishn'u; and at its left, that of S'iva. The symbol of the T. is the mystical syllable *om*, when (*o* being equivalent to $a + u$) *a* means Brahman; *u*, Vishn'u; and *m*, S'iva. See OM.

TRINCOMALEE′, a seaport town and magnificent harbour on the north-east coast of Ceylon, in 8° 34′ N., and 81° 12′ E. The town is built on a bold peninsula, which divides the inner and outward harbours. It is a place of great antiquity, but its ancient renown was due more to religious than political or geographical considerations, for it was here that the Malabar invaders of Ceylon built one of their most sacred shrines—the 'Temple of a Thousand Columns,' to which pilgrims flocked from all parts of India. This celebrated shrine was demolished by the Portuguese, who fortified the heights with the materials derived from its destruction, 1622 A.D. It was next held by the Dutch; but in 1672, during the rupture between Louis XIV. and the United Provinces, the French took T., which was abandoned by the Dutch in a panic. In 1782, the French admiral, in the absence of the British commander, took possession of the fort, and the English garrison retired to Madras. It was restored to the Dutch the following year, and they retained it until the capture of Ceylon by the British in 1795. The modern town is in no way remarkable, and, with the exception of the official buildings, makes a poor appearance. There are Hindu temples in barbarous taste, and religious festivals and processions to which a similar epithet may be applied. The Bay of T. is land-

locked, and presents a scene of tranquil beauty; its fine expanse of water is still as an inland lake, and equally sheltered. 'On comparing this magnificent bay,' says Sir J. E. Tennent, 'with the open and unsheltered roadstead of Colombo, and the dangerous and incommodious harbour of Galle, it excites an emotion of surprise and regret that any other than Trincomalee should have been selected as the seat of government and the commercial capital of Ceylon. As a harbour, Trincomalee is renowned for its extent and security; but its peculiar superiority over every other in the Indian seas consists in its perfect accessibility to every description of craft in every variation of weather.' The mean temperature for the year at T. is 81°·4. Pop. about 15,000.

TRINCOMALEE WOOD. See HALMALILLE.

TRI'NGA. See SANDPIPER.

TRINIDA'D, an island belonging to Great Britain, and the most southerly of the West India Islands, being in latitude 10° 30′ north. It is about 50 miles long, varying in breadth from 30 to 60 miles, and the area is about 1754 sq. m. Pop. (1881) 153,128. It is separated from the mainland (Venezuela) by the Gulf of Paria, and the extreme points on the west coast are only 13 and 9 miles respectively from it. The Dragon's Mouth entrance, to the north, is the deepest channel to the harbour; and the southern, or Serpent's Mouth, is shallow, owing to the deposits brought down by the Orinoco. The gulf itself is shoaling up from the same cause. The aspect of the island of T. is different from that of the Caribbean Islands generally: the mountains are not so lofty, and they extend in an east and west direction along the northern coast, clothed with stately forests, and their margins fringed with overhanging mangroves, dipping into the sea. From the double-peaked mountain called Tamana, are seen the lovely and fertile valleys and plains with which the other part of the island abounds. The island has several good harbours, and some tolerably large rivers.

The chief town, Port of Spain, is one of the finest towns in the West Indies. It was originally built of wood, but was burned down in 1808, and the town has since been rebuilt of the good stone procured in the neighbourhood. The streets are long, wide, well paved, clean, and shaded with trees. There is another town called San Fernando, with two or three pretty villages.

A remarkable phenomenon is a pitch lake near the village of La Brea, composed of bituminous matter floating on the surface of fresh water, about 3 miles in circumference, and 80 feet above the sea. The mineralogy of the island is but little known. The soil is very rich and productive. The climate is hot and moist; the thermometer ranges from 75° to 85°, sometimes 90°; and the rain-fall is about 75 inches.

The most important products are cocoa, sugar, rum, molasses, coffee, cotton, arrow-root, cocoa-nut oil, hides, &c. The value of the exports in 1870, £1,277,574; imports, £1,042,678. The increase in the population of the island—being about 25 per cent. from 1861 to 1871, as shown by the census returns of those years —was occasioned principally by the voluntary immigration from the neighbouring colonies and from India. Trinidad is a crown colony, ruled by a governor, an executive council of 3, and a legislative council of 13 members. There are 11 ministers of the Church of England, and 18 of the Church of Rome; there are also ministers of the Wesleyan and other denominations.

T. was first discovered by Columbus in 1498, and thus named by him because three mountain summits were first seen from the mast-head when discovered; but no permanent establishment was founded there until 1532 by the Spaniards. In 1783, it first fell into the hands of the British, who were confirmed in possession of it in 1802.

TRI'NITY, a river of Texas, U. S., formed by the union of two streams, West Fork and Elm Fork, which rise near the northern boundary of the state, and unite 150 miles south-east, the main stream flowing thence 550 miles in the same general direction to Galveston Bay, about 40 miles north of the city of Galveston. It is navigable 300 to 500 miles.

TRINITY, a river of California, rising near the coast-range, and flowing through a country of rich gold-mines, into the Klamath River.

TRINITY, THE DOCTRINE OF THE, is the highest and most mysterious doctrine of the Christian religion. It declares that there are three Persons in the Godhead, or divine nature—the Father, the Son, and the Holy Ghost, and that 'these three are one true, eternal God, the same in substance, equal in power and glory—although distinguished by their personal properties.' The most elaborate statement of the doctrine is to be found in the Athanasian Creed, which asserts that 'the Catholic faith is this: That we worship one God as Trinity, and Trinity in Unity—neither confounding the persons nor dividing the substance—for there is one person of the Father, another of the Son, and another of the Holy Ghost. But the Godhead of the Father, and of the Son, and of the Holy Ghost is all one; the glory equal; the majesty co-eternal.'

It is admitted that the doctrine is not found in its fully-developed form in the Scriptures; but it is supposed to be clearly revealed in its elements in the New Testament, and also to be indicated in many of the statements and revelations of the Old Testament. The form of expression in speaking of God in the Old Testament Scriptures—the plural *Elohim*, coupled with a singular verb; the apparent distinction recognised in the revelations to the Patriarchs and Moses between Jehovah and 'the Angel of Jehovah;' the mode in which 'the Spirit' and 'Word' of God, and 'Wisdom' (Proverbs viii.) are spoken of; and the gradual unfolding of the doctrine of a 'Messiah,' are all supposed to be indications from the earliest times of the truth of a plurality of persons in the Godhead; and in the New Testament Scriptures the doctrine is represented as clearly taught in the Trinitarian formula of baptism —the general character of the claims and prerogatives of Jesus Christ, especially the ascription to Him of the designation 'the Son of God,' and in the functions attributed to the Holy Spirit. The evidence is held conclusive of the equal divine nature and yet distinct personality of the Son and the Spirit along with God the Father. It is generally conceded, however, that the Christians of the 2d, and even of the 3d c., were far from having a clearly understood and recognised doctrine on this high subject. They were content for the most part to use Scriptural expressions in speaking of the Father, and the Son, and the Spirit, without defining articulately their relation to one another. It was not till the progress of opposing heresies sought, on the one hand, to degrade the divine dignity of Christ (Ebionitism in its various forms, and Arianism); or, on the other hand, to confound the personality of Christ with God the Father —a heresy known in its special form as Patripassianism — that the church was led to define in the Nicene Creed the relation of the Son to the Father; and further, in the Nicæno-Constantinopolitan Creed, the relation of the Spirit to the Father. This creed was specially directed against the opinions of Arius. A further clause was afterwards added, known as

the *filioque* clause, which determined the procession of the Spirit from the Son as well as the Father; but this clause, and the doctrine which it embodies, was never accepted by the Eastern Church, to whose finer speculative genius is owing the determination of the controversies which began in the 3d c. regarding the Divine nature. The Western or Latin Church had a far less refined genius for such speculations; and in so far as it meddled with them, has imparted to them a coarser and more contradictory aspect. What is known as the 'Athanasian Creed,' which is now well understood to be of Latin, and not of Greek origin, is a sufficient illustration of this.

It is not our part here to criticise the evidence for the doctrine of the Trinity, or the validity of the doctrine itself; it is enough to say that the evidence which we have briefly sketched in outline, has been accepted as satisfactory, not only by the Roman Catholic and oriental communions, but also by all the great Protestant communions. The only exception in modern times to the reception of the doctrine is in the case of the Socinians or Unitarians, who occupy in their teaching very much the position of the ancient Humanitarians (Ebionites). They reject the doctrine of the Trinity as incredible, and regard Christ merely as a higher prophet. There have, however, been various thinkers within the Christian church, such as Dr Samuel Clarke in the beginning of last century, who, while accepting generally the doctrine of the Trinity, have rejected the special terms in which it is defined in the Creeds, and whose views have been known as semi-Arianism.

TRINITY COLLEGE, Cambridge, was founded by King Henry VIII., in 1546, upon the site, and partly out of the revenues, of several more ancient foundations. The names of these were King's Hall, Michael House, Fyswicke's Hostel, Hovinge Inn, Gregory's, Margaret's, Catherine's, Gerard's, and Tyler's hostels. Of these, the first two deserve special mention. King's Hall (*Aula Regis*) was so called after its founder, Edward III., whose father, Edward II., had maintained 32 scholars, called king's scholars, but had died before completing his intentions. The Hall was founded in 1337. The master's stipend was fourpence, and that of each scholar twopence, per day, with two robes at Christmas. The revenues of King's Hall at the time of its surrender to Henry VIII. amounted to £214 per annum.

Michael House was founded 1324 A.D., by Hervey de Stanton, who was Chancellor of the Exchequer to Edward II. He dedicated his college to the Trinity, the Virgin Mary, St Michael the Archangel, and All Saints. When Henry VIII. united these smaller foundations into the one great college, henceforth called TRINITY COLLEGE, besides other endowments, he added the estates of twenty-seven dissolved monasteries, which made up the gross revenues to about £1700 per annum. Queen Mary added very largely to these benefactions, and provided for 20 additional scholars, 13 poor scholars or sizars, 4 chaplains, and a choir. Queen Elizabeth gave to the college a new set of statutes, by which the college was governed until the reign of Queen Victoria, when these statutes were revised. Subsequently, under the Cambridge University Commission (1859—1860), new statutes have again been given, by which several important changes have been introduced. Such Fellows as fill the office of bursar, tutor, or lecturer in the college, or professor in the university, are exempt from the necessity of taking holy orders, which must otherwise be done by all Fellows within seven years of taking the degree of Master of Arts. Marriage also is permitted to Fellows in a few exceptional cases, and to the chaplains and librarian. The Master of the college must be in holy orders, and the appointment is in the gift of the crown. The following are some of the more eminent names in the list of Masters: John Whitgift, who was raised to the see of Worcester; Thomas Nevile, Dean of Canterbury, who built the greater part of the cloistered court known by his name: he died 1615. To Dr Barrow, who was made Master in 1672, the college owes the finishing of Nevile's Court, and the erection of the Library, for which the designs were furnished by Sir Christopher Wren. The famous Dr Bentley was Master from 1700 to 1742. The late William Whewell was one of the most distinguished men that this college has produced, and one of the best of its Masters. He was a munificent benefactor to the college, to which he added one new court during his life; and at his death bequeathed his large fortune to the building of another, and to the founding of a professorship of International Law. See WHEWELL. To these may be appended the following few names of popular interest, with the dates of their death: Lord Bacon, 1626; Sir Edward Coke, 1634; Cowley, the poet, 1667; Lord William Russell, executed 1683; John Dryden, 1701; Samuel Pepys, the diarist, 1703; SIR ISAAC NEWTON, 1727; Richard Porson, 1808; Lord Macaulay, 1859. Of living men, it will not be invidious to select only the names of Adam Sedgwick, the geologist, and Alfred Tennyson, the Laureate.

The present society consists of the Master, W. H. Thompson, Regius Professor of Greek, 60 Fellows, 4 chaplains, librarian, 65 scholars, and 16 sizars.

With the exception of the Hall and the Library, the college buildings are not of any architectural pretensions. The statue of Newton by Roubiliac, in the ante-chapel, is one of the finest modern statues.—See Cooper's *Annals and Memorials of Cambridge*; Dyer's *History;* and the *University Calendar.* The judges, when on circuit, have the right of being entertained at this college.

TRINITY COLLEGE, Oxford. In 1290, Richard de Hoton, Prior of Durham, founded Durham College at Oxford, for the education of the student-monks of Durham. At the dissolution of the monasteries, the property of this institution was transferred by Henry VIII. to the newly erected chapter of Durham Cathedral. Its site and buildings, however, passed into the hands of Sir Thomas Pope, who, in 1554, obtained a licence from Philip and Mary to found a college on the spot, to be called T. C., for the maintenance of 20 scholars, of whom 12 were to be Fellows, and 8 scholars, properly so called. The scholars were to be elected from the founder's manors, and the Fellows from the scholars. In 1557, Sir Thomas Pope added four scholarships; and about the same time another was added by a Mr Blount. There are also three exhibitions. By the ordinances issued by the commissioners under 17 and 18 Vict. c. 81, the fellowships and scholarships are thrown open without restrictions; the latter are tenable for 20 terms, value £60 a year, besides rooms. This is the first college, after Balliol, which was founded by a layman, as were all colleges subsequent to this date. It is also remarkable as having been, like St John's, founded by a Roman Catholic after the Reformation. It presents to 10 benefices.

TRINITY HALL, Cambridge. This college, which is distinct from Trinity College, was founded 1349—1350 A.D. for Scholars of Canon and Civil Law, as well as for the education of clergy, by

William Bateman, Bishop of Norwich, who was also co-founder of Gonville and Caius College. It appears that the bishop was induced to found the college in consequence of the great pestilence which had recently swept away most of the clergy of his diocese, so that there could not be found sufficient to supply the parochial cures. In a bull of Pope Clement VI., dated at Avignon, 1349, it is stated that there were at that time no less than 1000 parishes in the diocese void of incumbents. The first Master was Robert de Stratton. There are thirteen fellowships, of which ten may be held by laymen for ten years, and are not vacated by marriage. There are also three law-studentships and twelve scholarships.—See Cooper's *Memorials and Annals*, and Dyer's *History of Cambridge;* also the *University Calendar.*

TRINITY HOUSE (properly called, The Corporation of the Elder Brethren of the Holy and Undivided Trinity), a corporation intrusted with the regulation and management of the light-houses and buoys of the shores and rivers of England. In 1518, a society under the above name was founded at Deptford by Sir Thomas Spert, Knight, and incorporated by Henry VIII. Its privileges were confirmed in 1658; and in 1680 its first light-house was erected; all the light-houses which had previously existed on the English coast having been built by private individuals under patents from the crown. By 6 and 7 Will. IV. c. 79, and the Merchant Shipping Act, 1854 (17 and 18 Vict. c. 104), private rights in light-dues were abolished, and the exclusive right of lighting and buoying the coast committed to the Board of Trinity House. The power of Trinity House to appoint and license pilots for the English coast is also regulated by this last-named statute. The Cinque Ports pilots, who had formerly been under control of a separate society, were, by 16 and 17 Vict. c. 129, and the Merchant Shipping Act, 1854, placed under the jurisdiction of Trinity House. Trinity House was in the practice of distributing certain funds arising from light and pilotage dues, and from the sale of ballast, for certain charitable purposes; but the right which the society possessed to the surplus of light-dues was done away with by the Merchant Shipping Act, 1854. This same act gave Trinity House a general supervision over the Commissioners of Northern Lights and the Ballast Board of Dublin, the corporations which have the charge of the light-houses and buoys of Scotland and Ireland respectively, subject to an appeal to the Board of Trade, to whose general superintendence Trinity House is also subject in matters relating to England. The light-houses of the Isle of Man are, by special arrangement, under the charge of the Commissioners of Northern Lights.

The corporation of Trinity House consists of a master, a deputy-master, nineteen acting elder brethren, eleven honorary elder brothers, and an unlimited number of younger brethren. The master and honorary elder brethren are chosen on the ground of eminent social position. The younger brethren all belong either to the naval service or the mercantile marine, and are admitted by the court of elder brethren. The deputy-master and acting elder brethren are elected by the court of elder brethren from such of the younger brethren as are possessed of the qualifications of having obtained the rank of commander in the navy four years previously, or having served as master in the merchant service on foreign voyages for at least four years. The Board discharges its duties by means of committees and sub-committees for special purposes, whose proceedings are, when necessary, subject to confirmation by the general court. Two elder brethren of Trinity House assist the Court of Admiralty at the hearing of every suit for collision, and occasionally in suits for salvage. Their duty is to guide the court by advice only; though influential, their opinion is not legally binding on the judges. The gross income of Trinity House for 1858 was £257,214, and the gross expenditure £172,285. The surplus income is chiefly devoted to the extinction of the debt incurred in pursuance of the act of 1846 for the purchase of private rights in light-houses.

TRINITY SUNDAY, the Sunday immediately following Pentecost Sunday, so called as being set aside for the special honour of the Blessed Trinity. The date of the origin of this festival has been a subject of much controversy. No such festival as Trinity Sunday was known to the Fathers of the early centuries. The most decisive evidence of its non-acceptance by the general church up to the 9th or 10th c., is the absence even to this day of any corresponding festival in the separated Greek Church; and although it seems quite certain that the festival was introduced in certain particular churches of the West, at earlier and varying dates, the general establishment of Trinity Sunday as a common festival of the whole Western Church, dates from a decree of John XXII., who died in 1334. Nevertheless, the mass and office peculiar to the day are of much greater antiquity, and may be traced, at least in part, in several sacramentaries and other liturgical books of the earlier centuries.—See Benedict XIV., *De Festis*, i. 2, 10; Binterim, *Denkwürdigkeiten Christ-katholisch. Kirche*, vol. v. part 1.

TRINO'DA NECE'SSITAS, three species of contributions, to which, in Anglo-Saxon times, all the lands of England, whatever their tenure, not excepting those of the church, were subject; viz. *Brygebot*, for keeping the bridges and highways in repair; *Burg-bot*, for keeping the fortresses in repair; and *Fyrd*, for maintaining the military and naval force of the kingdom.

TRI'O, in Music, a composition for three voices or for three instruments. The same term is also applied to a movement in $\frac{3}{4}$ time in a different key, which follows a minuet or other movement, and always leads back to the previous movement in the original key.

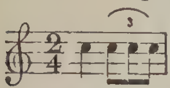
TRIPE DE ROCHE, a name originally given by the Canadian hunters to certain lichens, species of *Gyrophora*, which they are often forced to use as food, and now very generally in use as the designation of these plants. They are nutritious, but bitter, nauseous, and purgative. They have a leafy peltate thallus, variously lobed and notched—in *G. proboscidea* of a smoky-brown colour, and in *G. erosa* almost black; the shields are round, without stalks, covered with a black membrane, and marked with circles and plaits upon the surface. These lichens grow on rocks in northern regions, or on high mountains. They are to be found in abundance in Spitzbergen, and a species, well known as a native of the Scottish mountains, is found in the Himalaya at an elevation of more than 18,000 feet.

TRIPIT'AKA. See PIT'AKA.

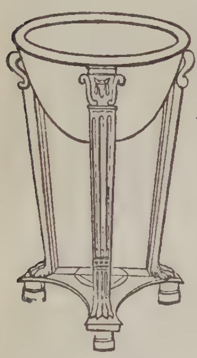
TRIPLE ALLIANCE, the name by which two different treaties are known in history; viz. 1. A treaty concluded in 1668 at the Hague between England, Holland, and Sweden, having for its object the protection of the Spanish Netherlands, and the checking of the conquests of Louis XIV. 2. An alliance concluded in 1717 between Britain, France, and Holland against Spain, which included among its stipulations that the Pretender should quit France, and that the treaty of Utrecht should be carried into effect as regards the demolition of

Dunkirk. The Protestant succession was guaranteed by this treaty in England, and that of the Duke of Orleans in France.

TRIPLET, in Music. When a note is divided into three in place of two parts—as when a minim is divided into three crotchets, a crotchet into three quavers, &c.—the group is called a triplet, and it is usual to place the figure 3 over it. Thus—



TRIPOD (Lat. *tripos*, Gr. *tripous*, three-footed), any article of furniture supported on three feet. Three-legged caldrons and bronze altars more especially came under this denomination in classical times; many of them are of exquisite workmanship, and richly decorated. The sacrificial tripod in its earliest form resembled the caldron, with the addition of three rings at the top to serve as handles. Of this description seems to have been the tripod at Delphi, from which the Pythian priestess delivered her oracles, with the addition, however, of a round flat plate on the top, on which the priestess sat while giving the response, while a laurel wreath lay on it at other times. Tripods of a similar form were given as prizes at the Pythian games; and at Athens, a tripod was considered an appropriate reward for a successful choragus. Some beautiful tripods were found at Pompeii; and there are several very interesting specimens in the British Museum. Analogous to the classic tripod, is Thor's *kettle* in Scandinavian mythology, which was probably the origin of the witches' caldron.



Tripod.

TRIPOLI, or TRIPOLIS (in its modern Arabic form, *Tarâbulus*), the ancient *Tripolis*, a seaport, and one of the chief commercial towns of Syria, capital of a pashalic in the eyalet or government of Sidon, is situated near the coast, on the eastern border of a small triangular plain running out into the Mediterranean, and on both sides of the river Kadisha. The town is substantially built of stone, with many remains of medieval architecture, and is supplied with excellent water by an aqueduct. It is surrounded by gardens of orange, lemon, mulberry, apricot, and other fruit trees, which are planted also in the town itself, and give the place a rich and picturesque appearance; but the low marshy neighbourhood renders it unhealthy. On the left side of the river stands the castle built by Count Raymond of Toulouse, in the 12th c., when the city was taken by the Crusaders. At the north-west apex of the plain already mentioned lies the port of Tripoli, called El-Mîna (the Landing-place), or the Marina, a small fishing village about 1½ miles distant from the town. The harbour, like other harbours on the Syrian coast, scarcely deserving of the name, is formed by a line of low rocky islets stretching north-west from the point. The trade of the place has of late much declined, being superseded by that of Beirût; its exports now consist chiefly of silk, sponges, and tobacco: there are also manufactures of soap. Pop variously stated at 13,000 and 20,000, and consisting of Mohammedans and Greek Christians It is the see of a Greek bishop. T. is regularly visited by the steamers of the French Messageries.

The ancient city of T. was situated on the plain, where immense numbers of granite shafts and other relics of antiquity are still found. Its name (the *Three Cities*, or the *Triple City*) was derived from the circumstance of its being founded by the cities of Tyre, Sidon, and Aradus, as an entrepôt for trade, and a point of federal union. It was for many centuries a place of great commercial importance.

TRIPOLI, a regency of the Ottoman Empire, and the most easterly of the Barbary States, North Africa, is bounded on the W. by Tunis, on the S. by the Libyan Desert and Fezzan, on the E.—if we include the plateau of Barca (q. v.)—by Egypt, and on the N. by the Mediterranean. Area roughly estimated at 200,000 sq. m.; pop. uncertain, but believed to be about 1,500,000. T. is less mountainous than the rest of Barbary, the Atlas range terminating here in a couple of chains running parallel to the coast, and never exceeding 4000 feet in height. There are no rivers in the country, and rain seldom falls during the long hot summers, but the dew is copious, and supports vegetation in favoured spots. The coast region (about 1100 miles in length) is very fertile about Tripoli and Mesurata, where all sorts of tropical fruits, grain, wine, cotton, madder, &c., are produced; but further east, along the shores of the Gulf of Sidra, sandy desolation reigns. The interior yields senna, dates, and galls; the carob and lotus are indigenous. Sheep and cattle are reared in great numbers, and T. is also noted for its small but excellent horses, and its strong and beautiful mules. The commerce of the country consists in exporting, principally to Malta and the Levant, the products of the country and of the interior of Africa (gold-dust, ivory, natron), which are brought hither in caravans across the desert. The imports (which consist chiefly of European manufactures) have been declining gradually of late years, owing mainly to two causes. The *first* is the new direction which the trade of Central Africa is assuming. By the Niger and its great tributary, the Benue, European manufactures are more rapidly and more economically conveyed to the northern intertropical regions than by the tedious overland route of the Great Sahara. The *second* cause is the abolition of the slave-trade, which, of course, has stopped the demand for all the commodities that alimented the traffic.

T. is subdivided into four *livas*, or provinces—Tripoli, Benghazi, Mesurata, and Gadames. The governor-general has the title, rank, and authority of a pasha of the Ottoman Empire. He is appointed by the sultan, and in his turn appoints the subordinate governors of the Tripolese provinces, who bear the title of beys. The military force of the country consists of a body of Turkish soldiers, some 10,000 in number, whose business is to keep down insurrections, but who were formerly wont to vary it by creating them. The natives (who comprise Libyan Berbers, Moors, and a few Arabs) pay to the imperial government, by way of tribute, a tenth of all the products of the soil; and there is, besides, a special tax imposed on every olive tree and date tree, on every camel, on all horned cattle, on sheep and goats, and on Jewish residents. Little wisdom and less justice are shewn either in the imposition or collection of the taxes.

In ancient times, T. (when we first read of it) appears to have formed the most westerly portion of the territory of Cyrenaica (Barca), or at least to have been tributary to the Cyrenæans, from whom, however, it was wrested by the Carthaginians. It next passed to the Romans, who included it within

the province of Africa and gave it the name of *Regio Syrtica.* About the beginning of the 3d c. A.D., it became known as the *Regio Tripolitana* (on account of its three principal cities, Œa, Sabrata, and Leptis, which were leagued together; whence its present name Tripoli), and was probably raised to the rank of a separate province by Septimius Severus, who was a native of Leptis. Like the rest of North Africa, it was conquered by the Arabs (see Barbary), and the feeble Christianity of the natives was supplanted by a vigorous and fanatical Mohammedanism. In 1552, the Turks got possession of it, and have ever since been the rulers of the country, though the authority of the sultan, up till 1835, had been virtually at zero for more than a century. In that year, however, an expedition was despatched from Constantinople; the ruling dey, Karamanli (in whose family the sovereignty had continued uninterrupted since 1714) was overthrown, and imprisoned; a new Turkish pasha, with vice-regal powers, was appointed, and the state made an eyalet of the Ottoman Empire. Several rebellions have since taken place (notably in 1842 and 1844), but they have always been suppressed.

TRIPOLI, called by the Turks *Tarabûlûs*, and probably the *Œa* of antiquity, the capital of the foregoing state, lies on a bit of rocky land projecting into the Mediterranean, and forming a bay. It is surrounded by high walls with bastions, and is irregularly built, but has beautiful gardens. There are 12 mosques, 3 synagogues, and 2 Christian churches. T. is the principal seaport of the country, and has important manufactures of leather, carpets, scarfs, &c. From T. caravans passed through the Desert of Sahara to Timbuktu, Bornu, &c., to obtain the products of Sudan; but this overland trade has greatly fallen off of late years. Tripoli being the centre of a large agricultural population, the native capitalists occupy themselves in money-lending to the peasantry. In 1870 the exports were £599,913, but in 1871, owing to the bad harvest and the French war, only £40,895. The imports of 1871 were £18,040. The steamers of the French, Russian, and Egyptian companies call at stated intervals. The population is estimated at 25,000. Though the majority are Moslems, nearly all the trade is in the hands of Jews and Christians.

TRIPOLI, a mineral substance employed in polishing metals, marble, glass, &c., so named because it was originally brought from Tripoli in Africa. It is a siliceous rock, composed of very minute particles, somewhat loosely held together, so as to yield readily to the nail, and to crumble down in water like rotten-stone. It has a coarse, dull, earthy fracture, is rough to the touch, and is of a gray, yellow, or red colour. The particles which entirely compose it are the siliceous frustules of *Diatomaceæ*, which occur unaltered in it, and are united together without any visible cement. Ehrenberg estimated that every cubic inch of Bilin Tripoli weighing 220 grains, contained 41,000,000,000 of these minute water-weeds. Deposits of Tripoli occur in the Tertiary rocks in every quarter of the world.

TRIPOLI'TZA ('three cities'), a town of Greece, under the Turkish rule capital of the Morea, now the chief town of the government of Mantinea, lies 22 miles south-west of Argos, and 39 south-west of Corinth, in a plain 3000 feet above the sea. It derives its name from being near the sites of the three ancient cities, Tegea, Mantinea, and Pallantium. In 1821, it was stormed by the Greek insurgents; and in 1828 razed to the ground by the troops of Ibrahim Pasha; it has since, however, been rebuilt. Previous to 1821, it had 20,000 inhabitants; the present pop. is only 7441.

TRI'PPANT, in Heraldry, a term analogous to Passant (q. v.), but applied to animals of chase.

TRI'PTYCH (Gr. *tris*, thrice, and *ptysso*, I fold), a set of tablets consisting of three leaves, each painted with a distinct subject, but joined together by hinges, and capable of being folded so as to present a new face. The general character of such tablets has been explained under DIPTYCH (q. v.), the difference of name, 'triptych,' 'polyptych,' being taken from the number of the leaves. In ecclesiastical use, the diptych has been already explained as commonly meaning rather the register of names inscribed on the tablets than the tablets themselves. The triptych, on the contrary, generally speaking, contained sacred pictorial representations rather than written registers or records.

TRI'REME (from *tres*, three, and *remus*, an oar) is the designation given in ancient times to a galley having three banks of oars. It is said to have been first employed by the Corinthians in their war with Corcyra, 664 B.C. In the Persian and Peloponnesian wars, triremes were the largest vessels employed; but at the time of Alexander, we find that galleys with four and five banks had gradually come into favour. In the Punic wars, the Carthaginians generally employed quinqueremes; and as the Roman triremes could have no chance against vessels with such high bulwarks, the Romans henceforth constructed their war-vessels after the model of the Carthaginian quinquereme.

The banks of oars were elevated above each other, but not perpendicularly; and the lowest rank of rowers having the shortest oars and easiest work, had the least pay. The trireme or quinquereme was also provided with a square sail, which was used when the wind was favourable for voyaging to relieve the labour of the rowers, but it was not employed in action. The crew consisted of about 200 men; and on a smooth sea, in speed and accuracy of manœuvring, the trireme was little inferior to a modern steamboat. In the earlier times, before the Persian war, and even later, victory depended more upon the number and valour of the soldiers on board, than upon the skill of the seamen. Herodotus mentions that besides the crew there were 40 marines serving on board each Ionian trireme. The Athenians improved this system by decreasing the number of fighting men, and trusting more to the skilful management of their vessels. In a fight, the aim of each trireme was not, as before, to grapple with its opponent, but to dash with the greatest momentum possible with its beak against the enemy's vessel, and strike it amidship, or, at any rate, disable his banks of oars on one side. Fighting men were not so much wanted for these tactics; and so we find later on, in the Peloponnesian wars, the number of marines in each ship reduced to ten. It is singular to see this system of ram-fighting coming once more into vogue. A contrivance for strengthening the prow of the trireme, and increasing its efficiency as a ram, gave the Syracusans their final victory over the Athenians in the harbour of Syracuse.

TRISA'GION, or **TRISHAGION** (Gr. *tris*, thrice, and *hagios*, holy; Lat. *tersanctus*, thrice holy), one of the doxologies in use in the Greek Church, which is repeated in the form of versicle and responses by the choir in certain parts of the liturgy. The words of the Trisagion are: '*Hagios O Theos, Hagios Ischuros, Hagios Athanatos, eleeson hemas!*' (O Holy God, O Holy Mighty One, O Holy Immortal, have mercy on us!) This doxology in its original Greek form, is one of the few fragments of the Greek liturgy which (like the *Kyrie Eleison*) are retained in the original language in the Roman mass. It occurs in the service of

Good Friday in the procession and veneration of the cross. See GOOD FRIDAY.

TRISMEGI'STUS (Gr. Thrice-greatest), an epithet applied to the Egyptian Hermes (q. v.), or Thoth (q. v.), by the Neo-Platonists, and the devotees of magic, alchemy, and mysticism generally, who looked upon him as the source of all mysterious doctrines. See HERMETIC BOOKS.

TRI'SMUS NASCE'NTIUM is a form of lock-jaw occurring in newly-born children, in consequence mainly of impurity of the atmosphere. In Iceland, this disease annually carries off a large proportion of infants between the fifth and twelfth days after birth; and it prevails in the island of St Kilda, in the Northern Hebrides, *four out of every five* of the infants dying between the eighth and twelfth day of their existence; the cause of this mortality being the contamination of the atmosphere from the manure which is laid upon the floors and trodden under foot to the depth of several feet. It is also very frequent and fatal in the West Indies, where it is known as the 'ninth-day disease.' Another of its names is 'the jaw-fall,' from the circumstance of the jaw relaxing and dropping on the breast shortly before death. By a proper system of ventilation the prevalence of the disease has been in many places greatly reduced. In so fatal a disease, it is almost unnecessary to refer to treatment. Immediate removal to a pure air, a warm bath, and a dose of castor-oil, should be tried.

TRISTAN DA CUNHA, an island in the South Atlantic, midway between South America and the Cape of Good Hope, lat. 37° 6′ S. It is about 20 miles in circumference. It was once a British military station established to keep a watch on the Island of St Helena during the imprisonment of Napoleon. At his death the soldiers were withdrawn, with the exception of a corporal named Glass and one or two companions, from whom a colony has sprung which numbered, in 1873, 80 souls. The island is apparently a solid mass of rock, rising abruptly from the sea and ascending to the height of 3000 feet. The crater of an extinguished volcano surmounts it, forming a dome 5000 feet high.

TRISTRAM is the hero of a British legend, which originally had no connection with the stories of King Arthur and the Round Table, although later minstrels sought to interweave them. Briefly, the legend goes as follows.

T., son of Rouland Rise, Lord of Ermonie, and Blanche Fleur, sister of Mark, king of Cornwall, having lost both parents at the period of his birth, is brought up for the first fifteen years of his life at the court of the monarch who had slain his father, after which he proceeds to Cornwall, and is acknowledged by his uncle, who appoints him his heir and successor. Having received a severe wound in a duel, he is cured by Ysolt or Ysonde, daughter of the queen of Ireland; and on his return to Cornwall, informs his uncle of the marvellous beauty of the Irish princess. Mark is charmed, and sends his nephew to Dublin, at the head of a select body of knights, to solicit her hand in marriage. The king's suit is successful, and T. escorts her on her voyage to England; but both having unwittingly partaken of a love-potion (which was intended for Mark), they are immediately inflamed with a criminal passion for each other, which is the source of all their subsequent misfortunes. Ysolt is married to the king of Cornwall; but by the help of her clever maid, Brenqwain, she contrives to have numerous secret interviews with her lover, and for some years succeeds in allaying the jealousy and suspicions of her husband. At last, however, T. is banished from Cornwall, and goes to Wales, where he performs prodigies of valour. His uncle again becomes reconciled to him, and invites him back to his court, where the amours of the incorrigible lovers are renewed. A renewed banishment is the consequence, and T. goes abroad to Spain, Ermonie, Brittany, in the last of which countries he marries another Ysolt, called, for distinction's sake, Ysolt *with the white hand*, daughter of the Duke of Brittany. After numerous romantic and impossible exploits, he sails for England to see his old mistress, and renew his guilty intercourse, for which the poet liberally provides facilities. After a time, he returns to Brittany, and once more engages in his favourite occupation of fighting, but is desperately wounded, and can only be cured by Ysolt of Cornwall. He despatches a messenger to the princess, telling him that on his return he is to hoist a white sail as he approaches the coast of Brittany, if Ysolt accompanies him; but if not, a black sail. The queen of Cornwall hastens to save her lover; and as the vessel nears the shores of France, T.'s wife, Ysolt *with the white hand*, recognises the white sail, and, fired with jealous hate at the thought of a rival's approach, hurries to her husband's chamber, and tells him the messenger's ship is coming in with black sails spread. T., in an agony of disappointed love, sinks back and expires. When the queen of Cornwall lands, and hears of his death, she rushes to the castle, throws herself on his corpse, and dies beside him. King Mark subsequently learns the story of the love-potion, and buries the twain in one grave, planting over Ysolt a rose-bush, and over T. a vine, which grew up so inextricably intertwined that no man could ever separate them—a beautiful symbol of their inseparable hearts, and of that sacred union which death had accomplished between those whom accident alone had made criminal, and whom fortune had often torn apart.

The popularity of the story in the middle ages was unbounded. The scene of the principal exploits, and the residence of the principal personages, is Cornwall, from which one is disposed to claim a British or Welsh paternity both for the legend and the literature; and this is the view that underlies Sir Walter Scott's argument in behalf of the purity of the metrical version of *Sir Tristram* which he published (ed. 1806) from the Auchinleck MS., and which is considered to be the composition of Thomas the Rymer (q. v.). He seeks to shew that although the story of Sir T. was well known in France before the time of the Scottish poet, the probability is that the latter gathered his materials from Welsh sources, and not from Norman minstrels. Without inquiring too curiously into the antiquity of the Welsh Triads (where the history of Sir T. occurs), it may be allowed that there is sufficiently good reason for adopting the hypothesis of a British origin of the work, and for assuming that it spread from Wales to Brittany, and thence over Europe, though some critics are of opinion, that while the *story* may belong to Cornwall, the *poem* is primarily a product of Armorican genius. As early as the middle of the 12th c., however, the legend had become a favourite throughout the whole of France; and it subsequently found its way into Spanish, Italian, German, Scandinavian, Slavic, and Greek literature.—See Michel, *Tristan; Recueil de ce qui reste des Poëmes relatifs à ses Aventures* (Lond. and Paris, 1835).

TRI'TICUM. See WHEAT and COUCH GRASS.

TRI'TON, in Greek Mythology, a son of Poseidon and Amphitrite, who dwells with his parents in a golden palace at the bottom of the sea. He usually figures as an attendant on his father, riding over the Mediterranean on a horse or other sea-monster, and soothing the turbulent waves by blowing his

shell-trumpet—his 'wreathed horn,' as Wordsworth calls it. The later poets speak of Tritons, in the plural, as a race of subordinate sea-deities, who are

Triton.

described by Pausanias as having sea-green hair and eyes, gills below the ears, human noses, broad mouths with the teeth of animals, scales on their bodies, and instead of feet, a tail like that of a dolphin. They were frequently represented in works of art.

TRI'UMPH (Lat. *triumphus*) was the name given in ancient Rome to the public honour bestowed on a general who had been successful in war. It consisted in a solemn procession along the *Via Sacra* up to the Capitol, where sacrifice was offered to Jupiter. The victor sat in a chariot, drawn by four horses—his captives marching before, his troops following behind. Certain conditions had to be fulfilled before a triumph could be enjoyed, and it was the business of the senate to see that these were enforced. Under the Empire, generals serving abroad were considered to be the Emperor's lieutenants, and therefore, however successful in their wars, they had no claim to a triumph. They received instead *triumphal decorations* and other rewards.

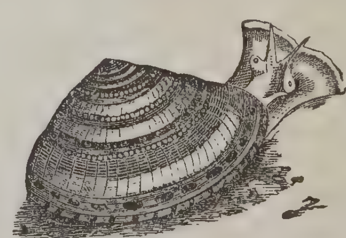
The appearance that Rome presented on the occasion of a triumph, especially in later times, was joyous in the extreme. All work was suspended; the temples were thrown open, and decorated with flowers; the populace were clad in holiday attire, and crowded the steps of all the public buildings in the *Via Sacra*, and the forum, or mounted the scaffoldings erected for the purpose of viewing the procession; banquets were spread before every door. As for the *imperator* himself, after having pronounced a eulogy on the bravery of his soldiers, he ascended his triumphal car, entered the city by the *porta triumphalis*, where he was met by the senate, and now the procession began. First marched the senate, headed by the magistrates; next came a body of trumpeters; then a train of carriages and frames laden with the spoils of the vanquished; then a body of flute-players, followed by the oxen doomed to be sacrificed, and the sacrificing priests, &c.; then the distinguished captives with bands of inferior prisoners in chains; after whom walked the lictors of the imperator, having the fasces wreathed with laurel. Next came the hero of the day—the imperator, in a circular chariot, attired in an embroidered robe (*toga picta*) and flowered tunic (*tunica palmata*), bearing in his right hand a laurel bough, in his left, a sceptre, and having his brows garlanded with Delphic laurel. He was accompanied by his children and his intimate friends. His grown-up sons, the legates, tribunes, and equites, rode behind; and the rear was brought up by the rest of the soldiery, singing or jesting at their pleasure, for it was a day of carnival and licence. When the procession had reached the Capitoline, some of the captive chiefs were taken aside, and put to death; the oxen were then sacrificed, and the laurel wreath placed in the lap of Jupiter. In the evening, the imperator was publicly feasted, and it was even customary to provide him a site for a house at the public expense.

The *ovation*, or lesser triumph, differed from the greater chiefly in these respects; that the imperator entered the city on foot, clad in the simple *toga prætexta* of a magistrate: that he bore no sceptre, was not preceded by the senate and a flourish of trumpets, nor followed by his victorious troops, but only by the equites and the populace, and that the ceremonies were concluded by the sacrifice of a sheep instead of a bull, whence, doubtless, the name *ovation* (from *ovis*, a sheep). The ovation, it is scarcely necessary to add, was granted when the success, though considerable, did not fulfil the conditions specified for a triumph.

TRIU'MVIRATE (Lat. a union composed of *three* men) is the name given in Roman history to the private league entered into between Pompey, Crassus, and Cæsar—the three most powerful men of their time; the object of which was to carry out their own schemes of political aggrandisement, in spite of the opposition of the senate. This compact was not a triumvirate, in the proper sense of the term: it had no legally constituted existence: it was, in fact, only a treasonable conspiracy of three men against the legitimate authority of the state. The term is less incorrectly applied to the division of government between Octavian (Augustus), Mark Antony, and Lepidus in the civil wars that followed the murder of Cæsar—an arrangement sanctioned, and therefore legalised by the senate. The former is usually called the *first*, the latter, the *second* triumvirate.

TRI'VIUM (Three Roads), the name given to the lower section of the Seven Liberal Arts (see ARTS), constituting the circle of study in the middle ages. It embraced Grammar, Logic, and Rhetoric.

TRO'CHIDÆ, a family of gasteropodous molluscs, of the order *Pectinibranchiata*, section *Asiphonata*. The shell has the aperture entire, closed with an operculum; spiral, and very generally top-shaped, as in the genus *Trochus*, the species of which are popularly known as Top-shells. The species are very numerous, and widely distributed.



Trochus.

They feed on sea-weeds, and some of them are found on rocks between high and low water mark. Many of them are very beautiful, and some of the small kinds are often employed to adorn head-dresses, and for other ornamental purposes, the epidermis and outer layer being removed. Several species are frequent on the British shores. Some of the tropical ones attain a comparatively large size. The T. are very closely allied to *Turbinidæ*.

TRO'CHILUS AND TROCHI'LIDÆ. See HUMMING-BIRD.

TRO'GLODYTES (Gr. *Trōglodytai*—Gr. *trōgle*, a hole, and *dyo*, to get into; hence cave-dweller), the name given by the ancient Greeks to various tribes or races of uncivilised men, who dwelt either in natural caverns, or in holes which they had dug for themselves in the earth. They are mentioned by Strabo as existing as far west as Mauretania, and as far east as the Caucasus; but perhaps the best known T. of ancient times were those of Southern Egypt and Æthiopia, where a considerable district of country was called *Regio Troglodytica*. They could not speak articulately, but shrieked or screamed like the lower animals; though it ought always to be remembered that the Greeks, from whom we have such statements, are not very trustworthy authorities in the matter of language, accounting every dialect which they did not understand, a barbarous jargon. The chief occupation of the T. was herding cattle, though we also read that they were hunters and robbers. They are likewise mentioned as serving among the light troops in the army of Xerxes. Their habits of life were rude and debased; they are reported to have eaten not only the flesh, but the bones and hides of their cattle; their drink is said to have been a mixture of milk and blood; and they had a community of wives. The wives tattooed their bodies; and the men, if not clothed in cattle-skins, went about *in puris naturalibus*. But the most revolting and unnatural of their practices was their treatment of the dead. They are reported to have bound the corpse neck and heels together, affixed it to a stake, pelted it with stones, amid shouts of laughter; and after they had buried it beneath a cairn of missiles, to have placed a horn on the top, and gone away!

What measure of truth there may be in such stories, it is now impossible to say; but archæological investigations into the pre-historical life of our own and other countries, have led to the conclusion, that a race of cave-inhabiters preceded in most countries the races that lived in houses built on the surface of the earth; and perhaps we shall not be far wrong, if we regard Troglodytism as the primitive state of all, or the greater part of, mankind.

TROGO'NIDÆ, a family of birds, ranked by

Resplendent Trogon (*Calurus resplendens*).

some naturalists, on account of their habits, in the order *Insessores*, and tribe *Fissirostres*; but more generally, on account of the formation of the feet—two toes before, and two behind—placed in the order *Scansores*. The T. are remarkable for the beauty of their plumage, which is soft, full, and brightly coloured. The bill is short, strong, with a wide gape; the tail generally long, in some species very long; the feet small, and in many, feathered almost to the toes. All the T. are tropical: they belong chiefly to the south-eastern parts of Asia, the Indian Archipelago, and South America. They abound most of all in South America. They inhabit forests, where they sit motionless on branches, waiting for insect prey, darting upon insects as they fly past. They make their nests in the hollows of decayed trees. Their flesh is highly esteemed for its delicacy and flavour. They are of small size. In brilliancy of plumage, some of them are excelled by no birds except humming-birds.

TROIZK, a town of Eastern Russia, on the border of Siberia, in the government of Orenburg, stands on the Oug, 420 miles south-west of Tobolsk. It is the seat of considerable commerce, especially during the summer months, at which season a large trade is carried on with the Kirghis and the Bokharians, who arrive in caravans from Central Asia. Pop. 6930.

TROLLOPE, MRS FRANCES, a novelist and miscellaneous writer of some eminence, was born in the year 1780. Her father was an English clergyman. In 1809, she was married to Mr Anthony Trollope, a barrister-at-law. In 1829, she went to America; and during a three years' residence in the United States, amassed the materials of her first book, *Domestic Life of the Americans*, published in 1832. This work attracted great attention; and its severe strictures were vigorously resented by those whom they caricatured and traduced. From this time forward, the literary activity of Mrs T. was nearly uninterrupted, and her name became one of the more notable of the time. Novels of Society and Impressions of Travel make up the sum of her works. Of her novels, the most successful is, perhaps, *The Widow Barnaby* (3 vols., 1839); with its sequel, *The Widow Married* (3 vols., 1840); followed by *The Barnabys in America, or Adventures of the Widow Married*. Mrs T. was a woman of strong talent, and her works are full of shrewd observation, and true, if at times somewhat coarse, humour. They were popular in their day, and very well deserved their popularity; but already they are well nigh forgotten. No list of them in detail seems needed. During the life of her husband, Mrs T. resided chiefly at Harrow. During her later years, much of her time was passed in Italy, where her eldest son, Thomas Adolphus, had taken up his abode. She died at Florence, 6th October 1863.

TROLLOPE, ANTHONY, second son of Mrs Frances Trollope, and one of the most popular novelists of the day, was born in 1815. He was educated at Winchester, and subsequently Harrow. While filling a responsible official situation in the general Post-office, he found, or made, leisure to amuse the public with a long series of novels, of very remarkable merit. The first work which decisively drew attention, *The Warden*, was followed by a continuation, *Barchester Towers*, which remains, perhaps, the cleverest of all his books. In rapid succession to these, came *Doctor Thorne*, *The Bertrams*, *The Three Clerks*, *Castle Richmond*, *Framley Parsonage*, *The Kellys and the O'Kellys*, *Orley Farm*, *The Small House at Allington*, *Rachel Ray*, *Miss Mackenzie*, *Hunting Sketches*, *The Belton Estate*, *The Claverings*, *Chronicles of Barset*, *Phineas Finn*, *He knew he was Right*, *The Vicar of Bullhampton*, *Sir Harry Hotspur of Humblethwaite*, *The Eustace Diamonds*, *The Way we now Live*, and *The American Sen-*

ator. Besides these works, Mr T. published pleasant volumes entitled *The West Indies and the Spanish Main* (1859); *North America* (1862); *South Africa* (1868); and *Life of Cicero* (1881); and occasionally contributed to English and American higher periodical literature. T. was esteemed one of the most popular of our novelists, sketching the superficial aspects of society with a charming facility of touch which rendered his works unfailingly agreeable. He died December 6, 1882.

His elder brother, THOMAS ADOLPHUS, has lived for many years at Florence, and is favourably known to the public by his *Girlhood of Catherine de Medici*, *A Decade of Italian Women*, and a graceful and touching Italian story, entitled *La Beata;* also *Paul V. the Pope and Paul the Friar*, *Beppo the Conscript*, and the *History of the Commonwealth of Florence* (Lond. 1865, 4 vols.), which was very favourably received.

TRO'MBONE (Ital. great trumpet), a large deep-toned brass instrument, of the trumpet species, but consisting of two separate parts, so constructed that the two ends of one fit into those of the other, and consequently, by sliding the one part in or out, the tube through which the air passes may be shortened or lengthened, and the pitch changed at pleasure. Three kinds of trombone are in general use, differing in pitch: the *Alto Trombone*, with a compass extending from  to ; the *Tenor Trombone*, with a compass from  to ; and the *Bass Trombone*, whose compass extends from  to . The music for these instruments is written on the alto, tenor, and bass clefs respectively. There is also a *double-bass* trombone, which is but rarely used. The trombone, if judiciously employed, is a very effective instrument in an orchestra—the tone is grander and more powerful than that of the trumpet.

TROMP, MARTIN HARPERTZOON, a celebrated Dutch admiral, was born at the Briel in 1597. When a boy, he went to sea with his father, a commander in the Dutch navy. In an engagement off the coast of Guinea with an English cruiser, his father was killed, and young T. made prisoner. His captors compelled him to serve as a cabin-boy for two years and a half, after which his history becomes for some time obscure. In 1622, we find him a lieutenant on board a Dutch ship-of-the-line; and two years afterwards, Prince Maurice gave him command of a frigate. In 1629, the famous Admiral Peter Hein took command of T.'s ship, and was killed by his side. Disgusted by some real or imaginary slight, T. about this time retired from the service. In 1637, he returned, and was created Lieutenant-admiral, by the Stadtholder, Frederick Henry. He was appointed to the command of a squadron of eleven ships. He now prosecuted a vigorous naval war against the Spaniards, taking in one celebrated action, fought on October 21, 1639, 13 richly laden galleons. But the events which were to render the name of T. immortal did not occur until the commencement of hostilities between England and Holland in 1652. On May 19 of that year, he encountered the English fleet under Admiral Blake. The Dutch were defeated with the loss of two ships of war. T. was for a while superseded in command by Ruyter and De Witt, but he was soon afterwards reinstated. On November 29, same year, he again encountered Blake in the Strait of Dover. This time, success was decidedly with the Dutch. The English fleet was obliged to retire; and T. sailed up the Channel with a broom at his mast-head, to denote that he had swept his foes from the seas. They were, however, not long in returning. On the 18th of February 1653, Monk and Deane having been united in command with Blake, they attacked T. near Portland, and defeated him, though only after a contest memorable for its obstinacy. It lasted three days, at the close of which Blake had taken or destroyed 11 ships of war and 30 merchantmen, killed 2000 of the enemy, and captured 1500. On June 2 and 3 following, another terrific battle took place off North Foreland, in which six Dutch vessels were captured, 11 sunk, and the remainder driven into Calais roads. On July 31, the warfare was again renewed off the coast of Holland. On this occasion, the Dutch lost 30 men-of-war, and Admiral T. was killed.

T. was a thorough seaman, homely in manner, benevolent in disposition, and enthusiastic in his calling. He was buried at Delft with great pomp and solemnity.

TRO'MSÖE, a small island on the north-west coast of Norway, in Finmark, lies between the island Kvalö and the mainland. It is four miles long, and about a mile and a half broad. On the eastern side of the island is the small but thriving town of the same name, the seat of a bishop. Russian vessels from Archangel and the White Sea visit this town, and bring corn, which they exchange for dried fish. Pop. about 3000.

TRON or TRONE weight, the most ancient system of weight used in Scotland, is so called from *trone*, a species of heavy beam or balance set up in the market-place, and employed for the weighing of heavy wares. The weights employed in the public markets formed the most convenient reference, and consequently tron weight became the standard. The tron lb. contained 20 oz., but from the custom of giving 'one in' to the score, was always reckoned at 21 oz.; this was the most general value; but it varied in the different market-towns between this and 28 oz. The later tron stone or standard weight contains 16 tron lbs., each lb. 16 tron oz., and each tron oz. 16 drops; the tron lb. is estimated to be equivalent to 1·3747 lbs. avoirdupois.

TROON, an important seaport in the county of Ayr, Scotland, 8 miles south-west of Kilmarnock, and 6 north of Ayr. The greater part of the town (which is not older than the present century) occupies a bare and level promontory; but along the broad and beautiful strand of Ayr Bay, known as the 'South Beach,' stretches, for nearly half a mile, a row of handsome villas and cottages, built chiefly for the accommodation of summer visitors. The place is yearly becoming more attractive as a sea-coast residence, partly on account of its extreme salubrity, and partly on account of the ample scope afforded by its wide stretch of sands for the simple amusements of the sea-shore. The harbour, which occupies the extremity of the promontory, is secure and spacious, and is much frequented. The principal exports are coal and iron, of which Ayrshire yields an abundant supply.

TROOP, in Cavalry, the unit of formation, forming the command of a captain, consisting usually of 60 troopers, and corresponding to a company of infantry. The officers of a troop are the captain, lieutenant, and cornet. Two troops form a squadron. The trooper's pay is 1*s.* 3*d.* a day.

TROO'PIAL (*Molothrus*), a genus of birds of the family *Sturnidæ* (see STARLING), having a short, thick, conical bill; long, pointed wings; and a

slightly rounded tail. The Cow T. (*M. pecoris*), also called Cow Blackbird, Cow-pen Bird, &c., is common in North America, passing the winter in the southern parts of the continent, and migrating northwards in spring. Its plumage is of a shining black colour, except the head and neck, which are

Troopial (*Molothrus pecoris*).

blackish brown. It is very generally to be seen in attendance on cattle, picking up the insects which they disturb, or which are attracted by their droppings. Like the cuckoo, it makes no nest of its own, but deposits its eggs in the nests of other birds.

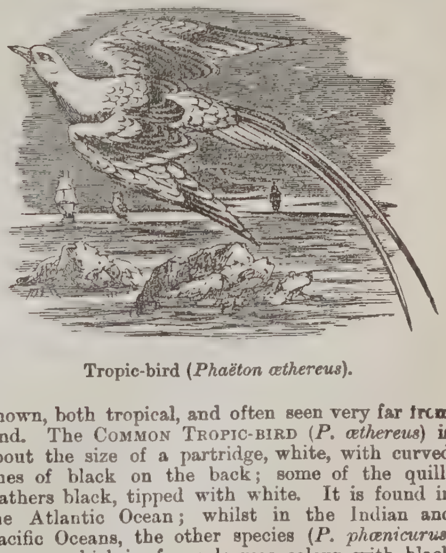
TROPÆ'OLUM, a genus of plants of the natural order *Tropæolaceæ*. This order is allied to *Balsaminaceæ* and *Geraniaceæ*. The species are not numerous, and are all natives of South America. They are smooth herbaceous plants, somewhat succulent, with an acrid or pungent taste, trailing or twining stems, and alternate simple or divided leaves, destitute of stipules. The species of the genus T. form the greatest part of the order, and have usually simple peltate leaves. *T. majus* is the well-known INDIAN CRESS of our gardens, the unripe fruit of which is often used to give pungency to pickles, under the name of *Nasturtium*. It is a native of Peru, and has long been much cultivated in America as an ornamental plant, climbing amongst bushes or on trellises, and taking hold by the curving stalks of its leaves; its stems from six to eight feet long, its foliage abundant, and its flowers large, orange, or dark red. The young leaves are used in salads. The Nasturtium is really a perennial, although it flowers within a few months from the time of sowing, and in America is always treated as an annual, not being able to endure the winter. *T. minus* is very similar, but of weaker growth, and its flowers smaller. *T. peregrinum*, although much more recently introduced into Britain than the Indian cress, has now become almost equally common, and is a great favorite in flower-gardens. It is popularly called the CANARY PLANT. Its stems are long and slender, and it speedily covers a high trellis. Several other species are frequent and fine ornaments of gardens and greenhouses. The tubers of *T. tuberosum* are eaten in Peru. Their taste is peculiar.

TROPE (Gr. *tropos*, a 'change,' a 'turning') is the name of a figure of speech which does not appear to differ from Metaphor (q. v.).

TROPHO'NIUS, in Greek legend, was the most skilful architect of his day, and was the son of Erginus, king of Orchomenus, or of Apollo. Along with his brother, Agamedes, he built the temple of Delphi and the treasury of King Hyrieus in Bœotia, which the two are said afterwards to have plundered. After his death, he was worshipped as a hero, and had a celebrated oracle at Lebadeia (Livadia) in Bœotia. 'The entrance to the oracle was a very narrow aperture on the summit of a mountain, protected by a marble parapet about two cubits in height, and by brazen spikes above it.' The votary who wished to enter the 'Cave of Trophonius,' in order to consult the oracle, after preparing himself for several days previously by purification and sacrifice, lay prone on his back, and put his feet into the cave, when he was caught by some unseen force, and violently pulled inside.

TRO'PHY (Lat. *tropæum*, Gr. *tropaion*, from *trepo*, to put to flight—the letter *h* in the English word being an intrusive letter) was a memorial of victory erected on the spot where the enemy had turned to flight. Among the Greeks (with the exception of the Macedonians, who erected no trophies), one or two shields and helmets of the routed enemy, placed upon the trunk of a tree, served as the sign and memorial of victory. After a sea-fight, the trophy consisted of the beaks and stern-ornaments of the captured vessels, set up on the nearest coast. It was considered wrong to destroy such a trophy, and equally wrong to repair it, when it had fallen down through time, for animosity ought not to be perpetual. In early times, the Romans never erected trophies on the field, but decorated the buildings at Rome with the spoils of the vanquished. Of this practice, we have a familiar instance in the *rostra* or beaks set up in the forum. In later times, pillars and triumphal arches were employed to commemorate victories. Besides these, in modern times, the humiliation of an enemy is rendered lasting by such devices as the bridge of Jena, of Waterloo, and by the distribution of captured cannon. Morally considered, this practice is no improvement upon the simple and perishable trophies of the ancient Greeks.

TROPIC-BIRD (*Phaëton*), a genus of birds, ranked by some in the family *Pelecanidæ*, by others in *Laridæ*. The bill is strong, pointed, and almost arched; the head completely feathered; the wings long; the tail short, except two feathers, which are very long and slender. Only two species are



Tropic-bird (*Phaëton æthereus*).

known, both tropical, and often seen very far from land. The COMMON TROPIC-BIRD (*P. æthereus*) is about the size of a partridge, white, with curved lines of black on the back; some of the quill-feathers black, tipped with white. It is found in the Atlantic Ocean; whilst in the Indian and Pacific Oceans, the other species (*P. phœnicurus*) appears, which is of a pale rose colour, with black wing coverts, and the long feathers of the tail red. The tropic-birds breed on high cliffs.

TRO'PICS (Gr. turning-points or limits) are two parallels of latitude on the terrestrial globe, passing through the most northerly and southerly points on the earth's surface at which the sun is vertical. On the Armillary Sphere (q. v.), consequently, the ecliptic (the representation of the sun's path) touches but does not cross the tropics. The tropics include between them all those points on the earth's surface at which the sun is ever vertical. The tropic north of the equator is called the Tropic of Cancer, because the sun at the summer solstice (at which time he is vertically over that tropic) enters the constellation of Cancer; and the southern one is, for a similar reason, denominated the Tropic of Capricorn. The tropics are not absolutely fixed at a uniform distance from the equator, but the limits of their variation are extremely narrow; on January 1, 1866, they were situated in 23° 27′ 14·77″ N. and S. respectively.

TRO'PPAU, the capital of Austrian Silesia, situated on the right bank of the Oppa, a tributary of the Oder, is a well-built fortified town, 184 miles north-east of Vienna by railway. It is the seat of the provincial government, and has a castle, cathedral, several palatial buildings, churches, and public schools, a library of 20,000 volumes, a museum of Silesian antiquities, important manufactures of machinery, cottons, linens, and beet-root sugar, and an active transit trade. Pop. 10,500. A diplomatic congress was held here in October and November 1810, which was subsequently removed to Laibach (q. v.).

TROU'BADOUR (Provençal, *trobar;* Fr. *trouver*, to find, of unknown derivation). In Provençal poetry (see TROUVÈRE), a troubadour was a polished and cultivated poet—what the Germans call a *Kunstdichter* (art-poet)—who did not make a trade of his muse, in opposition to the musician and jongleur, who wandered about the country singing for money. Yet this distinction only gradually shewed itself. At first, all classes of the community were nearly equally rude, and what pleased the peasant in the shape of song, pleased the prince also; but by degrees, a superior refinement and sensibility manifested themselves in the tastes and manners of courts, and this superiority found poetical expression in a more artistic kind of verse than had hitherto prevailed. Great nobles, princes, and kings who practised verse-making for their pleasure, or out of chivalrous gallantry, were always called troubadours; while inferior knights, court-attendants (M. Lat. *ministeriales;* hence *menestrels*, minstrels), and even citizens and serfs who lived by their art, or at least took money for the exercise of it, were sometimes called troubadours, and sometimes jongleurs. Under this last name were classed the musicians, singers, jugglers (a word, in fact, which is only a corruption of *jongleur*), &c.; all, in short, who did not themselves make or invent (*trobar*) poems, but only recited or chanted them, or whose business it was to accompany the singer on some musical instrument. The more celebrated troubadours had one or several such jongleurs in their service, as it was considered *infra dig.* for a poet to be his own fiddler. This new troubadour poetry (*art de trobar*), which it may be remarked was *lyrical*, while the popular minstrelsy was mainly of the *epic ballad* sort, exercised a considerable influence on the advancement of literature and culture generally; yet those who practised it never formed themselves into a guild, or into special schools, but preserved a certain free individualism, which gives a fine picturesqueness to the outlines of their history. At all the courts (great and small) in Southern France, Northern Spain, and Italy, they were esteemed a brilliant ornament of society; princes and fair dames (often themselves troubadours, as has been remarked) were proud of their praise, and their service of gallantry, or dreaded the biting raillery of their satiric muse; while, on the other hand, the majority of the troubadours gladly attached themselves to the court of a great prince or noble, sometimes praising their master in *sirventes* (service-songs), sometimes censuring him, but at any rate, always selecting some lady as the 'mistress of their heart,' to whom they, under a general or allegorical name, addressed their love-songs (*cansos*), whose cruelty they bewailed in songs of lamentation (*planes*), or whose death they mourned in sorrowful threnodies. Although the 'love-service' of the troubadours was often nothing more than an artificial gallantry, having more *esprit* than heart in it, yet not unfrequently the sport passed into fatal earnest, and adultery, murder, and revenge were the consequences.

Further, when, as often happened at great court-festivals, several troubadours were present, the latter used to indulge in competitions or verse-battles (*tensons*) among themselves, for the gratification of the high society assembled there; mostly on questions selected by the ladies from the 'Laws of Love;' one or more of these ladies sitting as umpires at such poetic jousts, and deciding who were the victors. But although the troubadours as a rule monotonously confined themselves to themes of gallantry, yet sometimes their muse, especially in its satiric moods, ventured into higher regions, and glanced at the general conditions of society, or the graver evils of the times—as the wars between the English and French armies in Southern France; the persecution of the Albigenses; the degeneracy of the clergy; the diminishing zeal for the Crusades, &c.; or they even descended to depict the life of the peasantry, and sang their adventures with shepherdesses, &c. in *pastoretas* and *vaqueyras*. The most illustrious patrons of the troubadour poetry were the counts of Provence, particularly Raimund Berengar III. (1167—1181), Alphonse II. (1196—1209), and Raimund Berengar IV. (1209—1245); the counts of Toulouse, as Raimund de St Gilles, who joined the ranks of the Crusaders in 1096, Raimund V. (1148—1194), and Raimund VII. (1222—1249); Richard *Cœur de Lion* of England, himself a troubadour; Eleanor, wife, first of Louis VII. of France, and afterwards of Henry II. of England; Ermengarde, Viscountess of Narbonne; the kings of Aragon, as Alfonso II. (1162—1196), Pedro II. (1196—1213), and Pedro III. (1276—1285); the kings of Castile, as Alfonso IX. (1188—1229), and more especially Alfonso X. (q. v.), surnamed the Wise; several Italian princes, as Bonifacio, Count of Montferrat, and after 1204 king of Thessalonica, and Azzo VII. of Este (1215—1263). These names also indicate the extent of territory on which the troubadour poetry was cultivated—viz., Provence, Toulouse, Poitou, Dauphiné, or briefly France south of the Loire; Catalonia, Valencia, and Aragon in Spain; and part of Upper Italy. It lasted for about 200 years (1090—1290), and one can distinguish three periods in its history: (1) The period of its genesis or birth, or its development out of mere popular minstrelsy into artistic poetry (1090—1140); (2) its golden age (1140—1250); (3) the period of its decline (1250—1290). The first of these periods is marked by a conscious striving after something finer and more poetic than the rude simplicity of the earlier verse; the second, by the loftiest expression of ideal chivalry and gallantry, and the most perfect development of artistic form; the third, by an ever-increasing serio-didactic tendency, and a degeneracy in poetic art. Thus the poetry of the troubadours rose, and ruled, and fell with that courtly chivalry which was at once its inspiration and its soul.

The long list of troubadours begins with GUILLEM IX. Count of Poitiers (1087—1127), the earliest of whom we have any knowledge, and whose verses exhibit partly the popular ballad style, and partly a more elaborate mode of poetic conception. His life and works appear to have been equally immoral.—After him comes BERNARD DE VENTADOUR (1140—1195), one of the first poets of the golden age of troubadour-minstrelsy. He was the son of a poor serf of the Vicomte Ebles II. of Ventadour. Recognising the talent of young Bernard, his master encouraged and assisted him; but his poetic enthusiasm was more excited by his passion for Ebles's wife, Agnes de Montluçon, than by Ebles's own commendations, and by the favour shewn him by later patronesses, Queen Eleanor, Joanna of Este, &c., all of whom he celebrated in fiery and delicate strains.—MARCABRUN (1140—1185), a foundling, was much feared for his power of satire, and was, in fact, murdered by the Castellan of Guian for an exercise of his fatal gift. He is reckoned the inventor of the art-song (*Cansós*). —JAUFRE RUDEL, Prince of Blaya (1140—1170), is equally famous for his languishing love-songs, and his romantic passion for the Countess of Tripoli, whom he never saw till he was at the point of death.—PEIRE D'AUVERGNE (1152—1215), son of a citizen of Clermont, called himself 'Master of the Troubadours;' yet his songs are more remarkable for their artistic finish than for their poetic inspiration.—GUILLEM DE CABESTAING (1181—1196), son of a poor knight, has become famous through his tragic love for the wife of his lord, Raimon de Roussillon.—RICHARD THE LION-HEART's song composed during his captivity in Austria, is widely known; and the songs of GUIRANT DE BORNEIL (1175—1220) have a manly and earnest ring about them; but perhaps the most celebrated of the whole fraternity was PEIRE VIDAL (1175—1215), a man wondrously endowed with poetic gifts, but who led so mad, wasteful, immoral a life, and committed such extravagant follies, that one doubts whether he was altogether sane. He was the terror of husbands.—BERTRAND DE BORN (1180—1195), equally celebrated as warrior and poet, played an important part in the wars of Henry II. of England with his rebellious sons, and was a zealous French patriot. His songs are for the most part of a political cast, full of martial ardour and the love of fatherland. In his lifetime, men dreaded his sharp tongue no less than his keen sword.—FOLQUET DE MARSEILLE (1180—1231) was the son of a Genoese merchant established at Marseille. After wasting his youth in amorous gaieties, in a fit of grief for the death of one of his many mistresses, he entered the church, rose to the dignity of Bishop of Toulouse, and signalised himself by the fanatical zeal with which he persecuted the Albigenses. Folquet's songs, 25 in number, are of an impassioned nature.—RAMBAUT DE VAQUEIRAS (1180—1207), a native of the county of Orange, in the south of France, was the son of a knight, and so great a favourite with Bonifacio II., Marquis of Montferrat, that the latter positively tolerated his sister's intimacy with the poet. He accompanied his patron to the East, and probably fell with him fighting against the Bulgarians. Some of his songs have found their way into different Romanic tongues.—PEIROT (1180—1225), in his condition and fortunes, curiously resembled his contemporary just mentioned. His pieces rank among the finest love-songs of the troubadours.—The MONK OF MONTAUDON (1180—1200) is a poet whose proper name is not known. He was sprung from a noble family belonging to Auvergne, and became Prior of Montaudon, but, notwithstanding, led the free life of a wandering poet. Finally, he betook himself to the court of Aragon; Alfonso II. made him Prior of Villafranca, where he died. He was more renowned for his satire than for his sentiment, and his songs are full of personalities directed against his brother troubadours—very cynical and very caustic.—ARNAULT DANIEL (1180—1200), a nobleman of Riberac, in Périgord, whom love made a troubadour. His powers of invention have been highly praised. Petrarch calls him *il grande maestro d'Amore*. Dante also celebrated his genius. —GAUCELM FAIDIT (1190—1240), son of a burgher of Uzerche, in Limousin, led at first, with his wife Guillelma Monja, the free and pleasant life of a jongleur; but subsequently left her, and became enamoured of the Countess Marie of Ventadour, who made him her troubadour. He would fain have been her paramour also, but she was too prudent; and so, to revenge himself, he carried on intrigues with other women; but his sweetest songs were those he sang in his lady's praise.—RAIMON DE MIRAVOL (1190—1220), one of the most lovable of the troubadours, although the women —his spouse not excepted, who was herself a poetess —abused him so bitterly, that for two years he was out of his mind.—SAVARIE DE MAULEON (1200—1230), a French baron, became Grand Seneschal of Aquitania, and took part with Raimund of Toulouse against Simon de Montfort. His political career was marked by great vacillation. As a poet, he is noted for his *Tenzone*.—PEIRE CARDINAL (1210—1230), son of a knight, was intended for the church, but preferred the life of a troubadour, and travelled with his jongleur from court to court. Jago I. of Aragon was his great patron. He was a master of the moralistic *Sirventes*, and assailed—but only with a sort of generalised satire—the nobles and clergy.—The last representative of the troubadours was GUIRAUT RIQUIER (1250—1294), a native of Narbonne. Although he had in his time many patrons, of whom the most distinguished was Alfonso X. of Castile, he was often in sore need; and his poems, full of complaints of the disrepute into which his order had fallen, may be regarded as the swan-song of troubadour poetry.—See Diez, *Leben und Werke der Troubadours* (Zwickau, 1829); Fauriel, *Histoire de la Littérature Provençale* (3 vols., Par. 1846); Galvani, *Osservazioni sulla Poesia de' Trovadori* (Modena, 1829), and *Fiore di Storia letteraria e cavalleresca della Occitania* (Milan, 1845); De Laveleye, *Histoire de la Langue et de la Littérature Provençale* (Brüss. 1845); Mahn, *Die Werke der Troubadours* (Berl. 1846); and *Die Biographien der Troubadours* (Berl. 1853); Brinckmeier, *Blumenlese aus den Werken der Troubadours* (Halle, 1849), and *Rügelieder der Troubadours* (Halle, 1846), Kannegiesser, *Gedichte der Troubadours* (Tüb. 1852), and *Ungedruckte Provenzal Lieder von Peire Vidal, Bern. de Ventadour, Folquet de Marseille, und Peirol d'Auvergne* (published by Delius, Bonn, 1853).

TROUS-DE-LOUP, or WOLF-HOLES, are hidden holes about 6 feet deep, and 4½ in diameter at the top. They are funnel-shaped, and have one or more pointed stakes at the bottom. They are placed often thickly about the glacis and approaches to a fortress; the object being to break the ranks and otherwise disorganise an attacking force.

TROUT (Fr. *truite*, from M. Lat. *tructa*, which, according to Diez, may be from Gr. *troktes*, the name of a voracious sea-fish, derived from *trogo*, to eat), the popular name of many species of the genus *Salmo*, as characterised by Cuvier, some of which are referred by Valenciennes to his restricted genus *Salmo*, some to *Fario*, and some to *Salar*. See SALMON. The name is given to some of the silvery

species, migrating to the sea, and to all the yellow species, which constantly inhabit fresh waters. The former are noticed in the article SALMON, the present article is devoted to the latter.

Trouts are found in almost all the lakes and rivers of the temperate and colder parts of the northern hemisphere. The COMMON T. (*Salmo fario* or *Salar Ausonii*) is widely diffused in the eastern hemisphere, abounding in almost all the lakes and rivers of the British Islands and the north of Europe. It is found even in very small streams, and almost to their mountain sources, but attains its largest size where there is considerable depth of water and abundance of food. An instance is on record of a T., caught in England, in a branch of the Avon at Salisbury, weighing 25 lbs.; but such a size is very rare, and even in ponds where the T. are regularly fed, they seldom exceed 10 lbs. A trout of 1 lb. or 1½ lb. is reckoned by the angler a very fine fish; and many a stream swarming with T. produces none nearly so large. The head of the Common T. is large; the eye large; the general form symmetrical, stouter than that of the salmon, the convexity

Common River Trout (*Salmo fario*).

of the outline of the back nearly similar to that of the belly; the tail is slightly forked, except in old fish, in which it becomes almost square, and sometimes even slightly convex. The teeth are numerous, strong, and curved; two rows of them extending along the whole length of the *vomer*, with no marked group at its front. The colour is more or less yellow, but the tint varies much in the T. of different waters, sometimes passing into greenish black or violet. The colour is brightest in the T. of clear streams. On the back and upper part of the sides there are numerous spots of black and red; the belly is silvery white. The spots on the sides vary much. The fins are light brown; the dorsal fin and tail with numerous darker brown spots. The varieties which the Common T. exhibits in tints and spots, has led to the supposition that several distinct species have perhaps been confounded as one, and attempts have been made to point out their characters; but these have not proved satisfactory to the greater number of naturalists. It is certain that the appearance of the T. is much affected by the character of the water in which it lives, and the food with which it is supplied. The T. of a river with a muddy bottom are very different from those of a clear stream, and those of a stream darkly coloured by moss are easily distinguished. The tint of the flesh varies as well as the external colours, being pink in some—the finest for the table—and white in others. It has been found that T. transferred from one locality to another soon change their tints.

The T. is very voracious, and readily devours almost any kind of animal food. Worms and slugs washed into rivers by rains are very acceptable to it. Small crustaceans are supposed to be the chief food of T. in some lakes and streams which are noted for the excellence of their produce. Small fresh-water shell-fish are also a favourite food of trout. Small fish of any kind which they can capture are their prey, and multitudes of salmon-fry thus perish. A gentleman well known to the writer of this article caught a large trout which had a very young viper in its mouth, bitten into three pieces; not yet swallowed, probably, because there was not room for it in the over-gorged stomach. The leaping of T. for flies in a summer day or evening adds to the charm of many a rural scene. Small T. often throw themselves quite out of the water; the larger ones in general merely rise to take struggling flies from its surface. The angler adapts his lures to the season and the weather. In spring and summer, when the weather is fine, the artificial fly is very successful; bait, generally the worm, is used in wet weather, or when the streams are much swollen by rains. The minnow is a good bait for large trout. No bait is more deadly than salmon roe, but the use of it is prohibited by law in Britain, for the sake of the salmon-fisheries.

The T. generally spawns in the end of October, when the lower jaw of the male becomes elongated, but not so much as in the salmon. The spawn is deposited in the same manner as that of the salmon, in gravelly beds, in running streams; and the T. of lakes ascend streams for this purpose. Where T. have no access to proper spawning-ground, recourse must be had to artificial means to increase the stock (see PISCICULTURE); but in many small streams their numbers seem incapable of being diminished by any amount of angling. The best feeding-grounds are often where there is no good spawning-ground within reach of the fish. The T. grows rapidly when it has abundant food. From instances of individuals kept in wells and ponds, it is known to attain an age of 30 or even 50 years.

Among the varieties of the Common T., one called the GILLAROO T. is found in Lough Neagh and other lakes of the north of Ireland. It attains a large size, is very thick in proportion to its length, and has much smaller teeth than the ordinary trout.

The LOCHLEVEN T. (*Salmo Levenensis* or *S. cæcifer*) is found in Loch Leven in Scotland, where the Common T. is also found, and is distinguished from it by

Lochleven Trout (*Salmo Levenensis*).

the more pointed pectoral fins; the much longer rays of the tail-fin, which is also more pointed at its extremities; and particularly by the number of the cæcal appendages, which are from 60 to 80 in the Lochleven T., whilst they do not exceed 46 in the Common Trout. The flesh of the Lochleven T. is not white or pink, but red. It attains a large size.

The GREAT LAKE T. (*Salmo ferox*) is the only other British species. It is found in some of the larger British and Irish lakes, and in the lakes of Scandinavia, seldom, if ever, ascending rivers, except for a short distance at the spawning season. It

attains a size of almost 30 lbs., is a very powerful, active fish, and tries the skill of the angler in no small degree. It differs from the Common T. in the longer muzzle, in the position of the fins, in having the tail square in all stages of growth, and in other characters. Its colour is generally deep purplish brown, passing into greenish or grayish yellow on the belly. The spots are large, and not numerous. The Great Lake T. feeds much on small

Great Lake Trout (*Salmo ferox*).

fishes, and is as greedy as a pike. It is taken by night-lines, or by trolling with strong tackle and a small trout or other small fish for bait. Young fish are taken with the artificial fly. The flesh of this species is very inferior in quality to that of the Common Trout.—Very different from it is the LAKE T. of the Lake of Geneva (*Salmo* or *Fario Lemanus*), which is a fish of excellent quality, and nearly allied to the Salmon Trout. See SALMON. It ascends the rivers which fall into the lake, as the Salmon T. ascends rivers from the sea.

North America has numerous species of trout. One of them, the COMMON BROOK T., or SPECKLED T. (*Salmo fontinalis*), is so similar to the Common T. of Britain, that it may almost be regarded as a variety rather than as a distinct species. It abounds in the streams of Canada and the more eastern British provinces, and in the northern and middle parts of the United States.—The NORTH AMERICAN LAKE T. (*Salmo confinis*) inhabits the deepest waters of the great lakes, and sometimes attains a weight of more than 60 lbs. It is dark-coloured, mottled with grayish spots. Its flesh is dirty yellow, and of very poor quality. It never takes the fly, but may be caught with the minnow, or a bait of fat pork. It is more sluggish than its congeners, and affords poor sport to the angler. There are several species of Lake T. in North America. The finest in quality, as well as largest in size, is the MACKINAW T. or NAMAYCUSH (*Salmo amethystus* or *namaycush*). It is not found in Lake Erie, nor in Lake Ontario, but in Lake Huron, Lake Superior, and the more northern lakes, even in those of the arctic regions. It inhabits the deepest parts of them, except in autumn, when it resorts to shallow water for spawning.—The SISKIWIT T. (*Salmo* or *Salar siscowet*) of Lake Superior is of large size, stout, thick, and of rich flavour, but so fat as to be almost unfit for food.—The RED-BELLIED T. (*Salmo* or *Fario erythrogaster*) of the lakes of New York and Pennsylvania, sometimes 2½ feet in length, is deep greenish on the back, lighter on the sides, which are spotted with red, the belly orange red.

The north-west of America has its own peculiar species of T., one of which, the OREGON T. (*Salmo trideus*), is found in almost every stream from the snowy peaks of the Rocky Mountains to the sea, and is very similar to the common T. of Europe.

TROUVÈRE, the name given in Northern France to the same kind of courtly or polished poet who, in southern France, &c., was called Troubadour (q. v.). Like the latter, he was usually attended by a jongleur, whose business it was to furnish an instrumental accompaniment to the songs which his master composed and sung. Sometimes, but rarely, the trouvère himself played on a harp. On the other hand, if minstrels and jongleurs were ambitious enough to aspire to original composition —as was the case, for example, with Adenez le Rois, Raymbert de Paris, &c.—they were nicknamed 'Bastard Trouvères' (*Troveor bastart*), or 'interloping rhymers' (*Contrerimoieurs*). This disdainful feeling of superiority was none the less likely to be strong that the poetry of the trouvères was high in favour at the northern courts, and that even kings and nobles were proud of the 'accomplishment of verse.' Among these princely and patrician amateurs were Thibaud of Champagne, king of Navarre, Jean de Brienne, Charles d'Anjou, Henri III. of Brabant, Pierre de Dreux, Count of Brittany, &c. The great patrons of the trouvères were the kings of France and England, the Dukes of Brabant, the Counts of Champagne, Flanders, &c.; while by the Anjou dynasty of the kings of Naples, their art was carried into Southern Italy, and by Henry of Burgundy into Portugal. The number of trouvères, in consequence, grew to be considerable; and one can still reckon the names and works of more than 150, of whom perhaps the most celebrated is the Castellan de Coucy.—See De la Rue, *Essais Historiques sur les Bardes, les Jongleurs et les Trouvères Normands et Anglo-Normands* (3 vols., Caen, 1834); Dinaux, *Trouvères, Jongleurs et Menestrels du Nord de la France et du Midi de la Belgique* (3 vols., Par. 1837—1843); Paris, *Le Romancero Français* (Par. 1833); Wackernagel, *Altfranz. Lieder und Leiche* (Basel, 1846), and *Collection des Poëtes Champenois* (Rheims, 1850).

TROVER, in the Law of England, is an action brought to recover goods from a person to whom they do not belong, but who has in some way obtained possession of them. It was founded on the old fiction, that the rightful owner had accidentally lost the goods, and the party in possession had found them, and would not give them up to such owner. It is practically an action to try the title to the goods, and therefore is of extensive application in the law of contracts, as well as other branches of law. The plaintiff, if successful, recovers the value of the goods as a satisfaction. The defendant is said to have illegally converted or appropriated the goods, and it is by the conversion of the goods that the damage is done, and for which the remedy is given.

TROWBRIDGE, a market-town of Wiltshire, stands on a rocky eminence in the valley of the river Biss, 10 miles south-east of Bath. In the church of St James, which dates from the 14th c., Crabbe the poet officiated as clergyman from the year 1814 to 1832, and his remains repose under a monument in the chancel. The town has long been the seat of woollen manufactures, and these, within recent years, have been carried on with much spirit and success. Cassimeres, kerseys, tweeds, and woollen cloths of the best qualities are manufactured. Many handsome villas have been erected outside the town by the wealthy manufacturers. Pop. (1881) 11,041.

TROY. The earliest traditions of the Greek people, as contained in their oldest poetry and history, represent the country on both sides of the Ægean as peopled by various races, either of genuine Hellenic, or of closely affiliated tribes. Among those who peopled the eastern or Asiatic coast are specially named the Pelasgi, the Leleges, the Caucones, the Carians, the Lycians, and the Trojans. These last, to whom Homer's poem has given a celebrity that throws all the rest into the shade, occupied the small country in the north-west corner of Asia Minor, best defined, perhaps, as the

region of Mount Ida, with its topographical dependencies. That the Trojans were either a Greek race, or some non-Hellenic people under a Greek dynasty, seems probable, from the absence in Homer of any such decided national contrast between Greeks and Trojans, as we find in medieval poetry between Christians and Saracens. Local legends represented them as closely connected with Crete; and Homer in the *Iliad*, xx., makes Priam the sixth in descent from Dardanus, the first of the dynasty, who was supposed to have come from Crete. The story of the Trojan war, which forms the subject of Homer's great poem the *Iliad*, is extremely simple. The Trojans, in the person of Paris, or Alexander, the son of the reigning monarch, Priam, are represented as having had certain dealings with the Achæans, or Greeks of the Peloponnesus, in the course of which the gay young prince carries off from the palace of Menelaus, king of Sparta, his spouse Helen, the greatest beauty of her age. To revenge this insult, the Greeks banded themselves together, and sailed against Troy with a large fleet. All the Greek tribes afterwards famous in history took part in this expedition; but the most notable were the Argives or Achæans—Greeks of the east and north part of the Peloponnesus, and adjacent isles; the Spartans—Greeks of the south-east district of the Peloponnesus; the Neleids—Greeks of the west coast of the Peloponnesus; the Bœotians, and the Thessalians. Of the Thessalians, the most prominent captain was Achilles; and the general command of the whole expedition was committed to Agamemnon, king of Mycenæ, as the head of the most numerous contingent, and at the same time the brother of the royal person whose hospitality had been so grossly violated. This well-appointed European army is represented as having spent nine years in besieging the god-built walls of the city of Priam without making any impression on its strength. A violent quarrel between Achilles and Agamemnon, breaking out in the tenth year, so weakened the invading force, that the Trojans, under Hector, pushed the Greeks back to the very verge of the sea, and almost set their ships on fire. This quarrel forms the subject of the *Iliad*. At the critical moment, however, the Thessalian captain is reconciled to the head of the expedition; and with his return to the field, the fortune of war changes; Hector, the champion of Troy, falls, and the impending doom of the city is darkly foreshadowed. The siege and sack of Troy did not fall within the plan of Homer's poem, but are narrated at length in the *Post Homerica*, a Greek poem by Quintus Smyrnæus, a poet of the decadence. The Greeks possessed a long series of popular poems called the Cyclic poems, in which the whole sequence of the Trojan story was narrated, giving completeness to the brilliant fragment, which has been adorned by the genius of Homer. From these poems—of which the abstracts are still preserved—Virgil derived those materials which he has used with such effect in the second and third books of his great poem. The Cyclic poems, besides the events in the Trojan war after the death of Achilles, contained an account of the various colonies in Italy and elsewhere believed to have been founded by the scattered chiefs of the expedition after their return home. Of these, the settlements of Diomede, Philoctetes, and Idomeneus, on the south-east coast of Italy, and that of Æneas on the banks of the Tiber, are the most famous. The chronology of the Trojan war, depending as it does mainly on artificial construction from genealogical data, is not, of course, trustworthy; but there are good reasons for believing that the generally received date of 1184 B.C. is not far wide of the mark. After the fall of the kingdom of Priam, the future story of Troy is short and uneventful. Under the Lydian kings, whose dynasty culminated in Crœsus, a New Troy—*Ilium Novum*—began to creep into notice, which, from the glory that belonged to its name, and the favour of Alexander the Great, Julius Cæsar, and other influential visitors, grew into some significance. The interest which attached to it, however, in its most flourishing estate was more antiquarian than political.

How far the events of the Trojan war, as found in Homer and the Cyclic poets, are to be taken as historical, depends upon the view which is taken of the general character of the materials of popular ballad poetry in all countries. That there is in the general case an under-stratum of historical reality, out of which the earliest popular poetry grows, may be assumed as certain. But how strong the tendency is, in early uncritical ages, to erect on this foundation a purely imaginary superstructure, need scarcely be mentioned. At the same time, there is a very great difference to be observed in the popular poetry of different nations, in respect of the greater or less amount of trustworthy historical matter which lies embedded in the imaginative conglomerate. The excess of the imaginative, fanciful, and altogether improbable element, is found in our own Arthurian and Carlovingian romances. In Homer, on the other hand, there is a sobriety of tone, a geographical clearness, and a general air of verisimilitude, which incline the reader to accept the historical reality of the main facts. In the first chapter of Herodotus, we find the Phœnicians practising the very same act of abduction, though in a more violent form, which the poet represents as having kindled the famous ten years' warfare between Greece and Troy; and even in the most general view, the war of Troy between rival peoples on the opposite sides of the Ægean, may be looked on as the natural overture of those great struggles, by which, on the same theatre afterwards, the fate of the world, indicated by the preponderance of the European over the Asiatic element, was more than once decided.

The PLAIN OF TROY is formed by the débris of the great chain of mountains which terminates the peninsula of Asia Minor on the north-west, where it is separated from Europe by the Sea of Marmora and the narrow strait of the Dardanelles. This chain of mountains is called Ida by Homer (*ide*, wood); and its highest peak towards the south side of the Troad, overhanging the Bay of Adramyttium, is celebrated by the same poet as Gargarus. Westward from this chain, the land slopes gradually down by a series of undulating ridges to the south coast of the Dardanelles. The plain included between these ridges and the sea is the plain of Troy. It is surrounded on all sides by elevated ground, by hills and mountains towards the east and south-east, and by rocky ridges or cliffs along the coast. At one place only does it open to the sea, and this is at the extreme north-west corner, where it meets the south end of the Dardanelles. Here there is a stretch of sandy shore about two miles in length, beginning behind the Turkish fort of Koumkale, and trending eastward. This is the only place where a fleet such as that described in the *Iliad* could effect a permanent landing; and here, accordingly, by general consent, the encampment of the Greeks is placed. The promontory which bounds this bay to the east is universally acknowledged as the Rhætean promontory of the ancients, while that on the west is the Sigean. Here, also, as the natural mouth of the plain, the principal river, by whose action mainly it was formed, finds its way into the sea. This river is the Mendereh, obviously a corruption of the Homeric

Scamander, called also by the poet Xanthus, from *xanthos*, that is, the *yellow* river, from the colour of its waters; a quality which has been noticed by most modern travellers. Looking up the plain from any of the heights about the mouth of the river in a south-easterly direction towards Gargarus, its course can be easily traced to a distance of about nine miles, where it emerges into the plain through a defile in the mountains. This distance of nine miles, therefore, is the extreme length of the plain of Troy. Its breadth is about three miles. It presents the appearance of 'a long tract of meadow-land, enclosed within a girdle of low, round-backed hills, and prettily garnished by many lines of trees, which skirt the water-courses.' These waters, with the single exception of the Scamander, are not large enough, according to our usage, to deserve the name of rivers, but are mere mountain-torrents or brooks, generally dry in summer, some of them nothing better than a sort of natural drains or ditches. Those deserving of mention are three: the first flowing from the chain of Ida westward into the plain, about three miles from the sea, called the *Dombrek;* the other in the same direction, about five miles further up, called the *Kimair.* The third streamlet rises at the head of the plain, near the Turkish village of Bunarbashi, and creeping along the bottom of the slope towards the Archipelago, forms the boundary of the plain on the west, and empties itself into the Mendereh, about two miles above its mouth. One of these streams must be the Homeric Simois.

The topography of a plain so famous in the history of human civilisation has, of course, occupied the attention of the learned both in ancient and modern times; and a considerable library could be formed of volumes in which this region has been described, and its most famous localities discussed. The topographical result of these voluminous discussions can, however, now be given in a very few sentences. In the first place, after seventy years of confusion and hallucination, it may be regarded as certainly established, that the Mendereh is the Scamander. It is also universally allowed that *Novum Ilium*, or New Troy, occupied the site of Hissarlik, on an eminence about four miles from the mouth of the river, on its right bank, near the bend of the Dombrek. It is also a matter of general consent, that the great tumulus or barrow, near the Sigean promontory, where the Dardanelles broaden up into the wide Ægean, is the veritable monument of Achilles, described by Homer in a famous passage of the *Odyssey;* but beyond these three points, it cannot be said that any part of the classical topography of the plain has been ascertained with certainty. The great point to determine, of course, is the site of the Homeric Troy, the capital of the empire of Priam; but this is a matter which, in default of inscriptions, can be ascertained only by previously deciding which of the three streamlets above mentioned is the true heir to the legendary glories of the Homeric Simois; for between the Scamander and the Simois the tide of battle rolled to and fro, as Homer expressly tells us; and at the head of the plain between these two rivers the town of Troy must certainly stand. Those who hold with Strabo among the ancients, and Maclaren among the moderns, that the Dombrek is the Simois, have strong grounds for maintaining that New Troy was built upon the site of Old Troy, and that no further search is necessary; while they who look on this point as suspicious, must recognise the Simois in the river of Bunarbashi, and the site of the Pergamus of Priam on the plateau at the great bend of the Scamander, about a mile to the eastward of the village of Bunarbashi, where the substructions of an ancient city have been lately excavated. Those who wish to see this nice topographical question discussed in the most masterly style, will read *The Plain of Troy Described*, by Charles Maclaren (Edin. 1863), on the one side; and *Ueber des Homerische Ilion*, by Professor Welcker, in his collected tracts (Bonn, 1845), on the other. A succinct exposition of the arguments on both sides will be found in Professor Blackie's notes to the *Iliad*, Book xxi. The literary history of this topographical question, commencing with the work of Le Chevalier, a Frenchman, translated into English by Professor Dalzel in 1791, is extremely curious; but the most distinguished scholars and topographers being now agreed that the Mendereh and the Scamander are identical, it is not necessary to make any allusion to the wonderful discovery of 'the wells of the Scamander,' by which Le Chevalier imagined he had made himself immortal. Dr Schliemann, who lately carried on a systematic investigation of the supposed neighbourhood of ancient Troy, believes he has found at Hassarlik its veritable site. In July, 1872, he discovered a very large collection of gold, silver, and copper implements, undoubtedly of great antiquity. He considers that these are part of the treasures of ancient Troy, probably buried for safety on the night of the conflagration.—See *Troy and its Remains*, by Dr Henry Schliemann, London, 1875.

TROY, a city of New York, U. S., on the east bank of the Hudson River, at the head of steamboat navigation and tide-water, 151 miles north of New York City, and 6 miles north of Albany, built upon the alluvial flats of the river and hills, called Mount Ida, on the east side. Winants Kill and Poesten Kill, two small streams, having each a series of falls, furnish water-power to mills and factories, besides that given by a dam across the Hudson. At T. is the principal outlet of the canals connecting the Hudson with Lakes Champlain, Ontario, and Erie; and it has railway connections with New York, Boston, and the north and west. The Union Dépôt, in the centre of the city, is one of the largest in America, 60 trains arriving and departing daily. The iron furnaces and manufactories are among the largest east of the Alleghanies, being furnished with the magnetic ores of Lake Champlain, and the hematitic ores of Western Massachusetts. The coal is brought from Pennsylvania and Maryland. The chief iron-works are those for bar-iron, railway-spikes, nails, locomotives, stoves, hot-air furnaces, hollow ware, machinery, agricultural implements, &c. Other important manufactures are those of railway cars, coaches, omnibuses, cotton and woollen goods, breweries, distilleries, flour, boots and shoes, shirts and collars—the latter employing 4500 persons, with extensive machinery. There is also the largest manufactory of mathematical instruments in the country. The property which reaches tide-water by the canals centering at T., including lumber, is valued at 17,000,000 dollars annually. The city contains 33 churches, 28 public schools; the celebrated Female Seminary founded by Mrs. Emma Willard, the Rensselaer Polytechnic Institution, with 14 teachers and 100 students; asylums, academies, &c. T. was settled by the Dutch in 1752, and incorporated as a village in 1801. Three times it has been nearly destroyed by fire; in 1862, the loss amounted to 3,000,000 dollars. Pop. (1840) 19,334; (1850) 28,785; (1860) 39,235; (1870) 46,465; (1880) 56,747.

TROYES, a town of France, formerly capital of the province of Champagne, and now of the dep. of Aube, on the left bank of the river Seine, 103 miles east-south-east of Paris by railway. It is a very old-fashioned place, and most of the houses are of

wood. The principal buildings are the cathedral, dedicated to St Peter, a splendid specimen of *flamboyant* Gothic, founded in 872, and rebuilt between the 13th and 16th centuries; the churches of St Urban, the Madeleine, St Pantaleon, and St Remi, the Hôtel de Ville, a public library, containing 53,000 vols. and 5000 MSS.; a Museum, the Palace of Justice, the Exchange, Merchants' Hall, and various educational institutions. T. is not so populous or important as it was in the middle ages. Even as late as Henry IV.'s time, it had more than 60,000 inhabitants; in 1881, the pop. was 45,824. It carries on numerous cotton and woollen manufactures, and, as the centre of a rich agricultural region, it has a large transit-trade.

T., anciently the capital of the Celtic Tricassii, was called by the Romans *Augustobona;* later, *Civitas Tricassium;* and then *Trecæ* (a corruption of Tricassii), whence the modern Troyes.

TROY-WEIGHT. The origin of the term 'Troy' is unknown; some consider it to be a corruption of *le roy*, as the troy pound was, till recently, the standard pound (*pondus regis*); some derive it from *Troy novant*, the monkish name for London; while the majority of philologists and lexicographers profess to see the origin of the name in the town of *Troyes*, in France, an important centre of commerce during the middle ages, which hence *may*, like the towns of Cologne, Toulouse, and others, have had its own special system of weights; though why the term should have migrated to Britain, and been exclusively employed there for so long, is not at all evident. A Troy pound (of what value is unknown), is first mentioned in Britain in 1414, long before which period the standard pound of 12 oz., as well as another pound (the Tower pound) of 12 oz., was in use. The term 'Troy' was first applied to the standard pound in 1495, but at the same time no change seems to have been made in its value, and it continued, as before, to be exclusively employed by the dealers in the precious metals, gems, and drugs. See POUND. The troy pound contains 12 oz., each ounce 20 penny-weights, and each penny-weight 24 grains; thus the pound contains 5760 grains, and is to the avoird. pound as 144 to 175; while the troy ounce is to the avoird. ounce as 192 to 175. For medicines, the troy pound is divided into 12 oz., each ounce into 8 drachms, each drachm into 3 scruples, and each scruple into 20 grains. The old English pound, to which the term Troy was afterwards applied, was doubtless the pound of silver; and the Tower pound of 12 oz. differed from it only by ¾ths of an ounce.

TRUCE, a suspension of hostilities between two armies or states for a period specially agreed upon. During a truce, it is dishonourable to occupy more advanced ground, or to resort to any act which would confer advantage. A truce requires ordinarily to be confirmed by the commander-in-chief to become binding. It is lawful to break it before the prescribed period, on notice previously agreed on being given to the opposite party. This is called denouncing a truce.

TRUCE OF GOD. See GOD'S TRUCE.

TRUCK-SYSTEM (French *troquer*, Scotch *trock*, to barter or exchange) is applied to the practice of paying workmen in goods instead of current money. There is no question about the bad social influence of such an arrangement in the ordinary staple and steady systems of productive industry, though there are cases where it is beneficial—as where new works bringing together large bodies of men are started in districts where there is little or no traffic. In such cases, an arrangement to supply the workmen from temporary stores established by their employers, or by persons in communication with them, will be better than leaving the families so collected at the mercy of miscellaneous speculators, probably insufficiently supplied with capital. The Truck Act of 1831 (1 and 2 Will. IV. c. 37) imposes penalties on the employer who pays in goods in certain producing trades. The feature which was supposed to be the supreme triumph of the act, however, and was to make it self-working, was, that all wages so paid were to be a blank. The workman so remunerated had still an action for his wages, and in various shapes it was provided that the goods should be no 'set off' against the money value of the labour. The Report of a Select Committee appointed in 1842 to inquire into the extent and operation of the truck-system, found that, notwithstanding the act, it flourished extensively in several productive trades—as in coal and other mines, iron-works, quarries, and various kinds of manufactories; and they reported that its prevalence had a very pernicious effect on the families of the working-men. In the year 1853, Mr J. H. Burton was employed by government to investigate the system as it operated in Scotland; and his Report of the results was presented to parliament. He found that, however pernicious it might be, it was a thing beyond legislative control, and that the attempts to suppress it, in many cases only strengthened its hold, by the completeness of the organisation for carrying it out. One, and a perfectly simple, form is this. At a large iron-work, say, the stated payment of the men is monthly. From their improvident habits, however, they are ever requiring advances. These are at once paid in cash. There is at the same time a neighbouring store; it may be owned by the same proprietors as the iron-work, or it may be let to some other person at a rent estimated, not at the value of the premises in the market, but at that of the trade which is guaranteed to the tenant. At this store, all purchases are made in cash, and all comers may purchase as at any other shop. The books of the two establishments, however, shew how much of his advances each workman has expended at this store. A man says he wants a pound in advance of his monthly wages. He gets the money, and no questions are asked. By comparison of books, however, it comes out how much of this is spent in the store. When he asks another advance, it may be refused, for reasons known to both parties, but not told. In some instances, the registers are so complete that when the workman pockets his advance, he knows, though he has never been told, what proportion of it he must spend at the store to keep in the advanced pay-list. It was found not unusual to limit the free expenditure to 5 per cent., or a shilling in the pound. Thus the system has its foundation in the improvidence of the class it affects. Until that disease is cured, and the workman can wait for the periodical pay-day, he must take his advances on the employer's conditions. As a general economy, the truck-system does not pay. If it is supposed to be profitable, it is from the fallacy, that two profits may be made on one capital. The capital which the iron-master devotes to dealing in beef, tea, and beer, must be subtracted from the capital embarked in his iron-work. This is the business to which he professes to devote himself, and for which he believes himself to have peculiar faculties. His truck-shop either diverts his attention from his main business, or he must hand it over to a hireling, who certainly will not work the capital so embarked as profitably as that portion employed in the iron-work, and superintended by the owner himself. But in great trades where truck is the established rule, the

individual employer cannot help himself. The rate of wages is adjusted on the scale of a portion coming back in the shape of the profit on purchases at the shop. The employer must therefore keep a shop, unless he can get his men to be so reasonable as to work for him on less wages than their neighbours nominally get; but he would be a person of miraculous reasoning powers who would persuade working-men to do that.

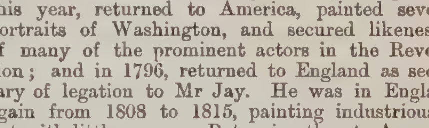
TRUFFLE (*Tuber*), a genus of fungi of the section *Gasteromycetes*; globose, or nearly so; of a fleshy substance, with a distinct skin, the whole substance pervaded by a network of serpentine veins, which are the *hymenium*, and bear the spore-cases in minute cavities. The species are not numerous; they are very generally diffused in temperate parts of the world; they are subterranean, often found at the depth of a foot or more in the soil. Some of them are amongst the most highly valued of esculent fungi. The COMMON T. (*T. cibarium*) is of a black colour, and has a warty surface. It varies in size from that of a large plum to that of a large potato. On account of its agreeable flavour, it is used in the preparation of many dishes. It is common in the central and southern parts of Europe, chiefly in loose soils, in woods and pastures, as in the chestnut woods of France and Italy. In England, it occurs, pretty abundantly, in the downs of Wiltshire, Hampshire, and Kent. Other species, as *T. æstivum*, *T. rufum*, and *T. moschatum*, are found in some parts of France, Italy, and other countries of Europe, and are sought after and used in the same manner as the Common Truffle. It has recently been discovered that the English species are more numerous than was formerly supposed; truffles have also been discovered in localities in the south of England where their existence was formerly unknown. The gathering of truffles is the occupation of many persons in the places where they abound. They are dug up with a kind of hoe or pick. Dogs are trained to seek them, and readily discover by the scent the spot where they grow underground. The stirring of the soil in the gathering of truffles seems to increase its productiveness. No particular kind of dog is specially employed for truffle-seeking; but one of which the parents are truffle-dogs is preferred, as it is said to be more easily trained. In some parts of France, pigs are also trained to seek truffles. In Germany, the name BLACK T. is given to the Common T., and that of WHITE T. to *Rhizophagon album*, a species of a nearly allied genus, which has also been found in England. It grows half above ground, is of a whitish-red colour, and is generally of the size of a large walnut. It is less aromatic than the Common T., but is used in the same way.

Truffle (*Tuber cibarium*).

TRULLAN, the name (derived from the hall—Gr. *troullos*—of the palace in which the Fathers assembled) given to the council also called *Quinisext* (q. v.).

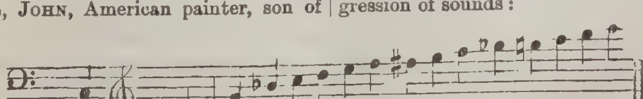
TRUMBULL, JOHN, American painter, son of Governor Jonathan Trumbull (said to have been the original 'Brother Jonathan') of Connecticut, and brother of General Jonathan Trumbull, aide-de-camp to General Washington, was born in Lebanon, Connecticut, 6th June 1756, was educated at Harvard College, and devoted himself to painting. He had completed two pictures, the 'Battle of Cannæ,' and the 'Judgment of Brutus,' at 19, when the war of the Revolution broke out, and he joined the provincial army before Boston as adjutant of the 1st Connecticut Regiment. The execution of drawings of the British works procured his appointment as aide to Washington, and soon after, that of brigade-major. In 1776—1777, he served under Gates and Arnold as adjutant-general; but, offended with the action of Congress respecting the date of his commission, he resigned, and resumed the palette. In 1780, he came to London, *viâ* France, where he was making rapid progress under the instructions of Sir Benjamin West, when, during the excitement occasioned by the execution of Major André, he was thrown into prison. The king, George III., promised West that his life should be spared, but he was kept eight months in prison, and then released on condition of leaving the kingdom. After the war, he returned, and resumed his studies. His 'Priam receiving the Body of Hector,' painted at this period, is in the gallery of the Boston Athenæum. In 1786, he produced the first of a series of modern historical and military works, the 'Battle of Bunker Hill,' followed by the 'Death of Montgomery,' 'Sortie of the Garrison from Gibraltar,' exhibited in London in 1789, and engraved by Sharp. He, this year, returned to America, painted several portraits of Washington, and secured likenesses of many of the prominent actors in the Revolution; and in 1796, returned to England as secretary of legation to Mr Jay. He was in England again from 1808 to 1815, painting industriously, but with little success. Returning then to America, he was employed by Congress to paint four large national pictures for the Rotunda of the Capitol at Washington—the 'Declaration of Independence,' 'Surrender of Burgoyne,' the 'Surrender of Cornwallis,' and the 'Resignation of General Washington, at Annapolis, December 23, 1783.' These pictures are chiefly valuable as collections of portraits. He afterwards completed a gallery of all his historical pictures, 57 in number, on a smaller scale, which became the property of Yale College, and has great historical value. He was the President of the American Academy of Fine Arts from its foundation in 1816, until the formation of the National Academy in 1825; and died in New York, November 10, 1843.

TRUMPET, a musical instrument of great antiquity, which, in its present form, consists of a



Trumpet.

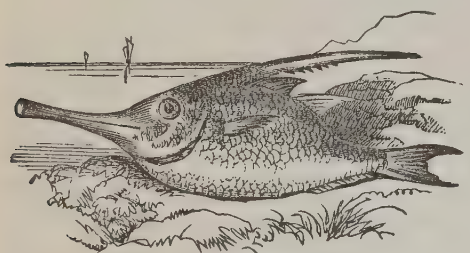
tube eight feet long, less in diameter than the horn, doubled up in the form of a parabola, and sounded by a mouth-piece. It produces the following progression of sounds:



Music for the trumpet, as for the Horn (q. v.), is written in the key of C, the key to which the instrument is to be adapted being pointed out by the composer. The pitch is an octave higher than that of the horn. Trumpets in the keys of C, D, and E♭ are most used; but there are also trumpets in A, B♭, E, F, and G. To enable the trumpet to give a complete series of semitones, finger-keys and sliding tubes have been introduced by some makers, rather to the detriment of the freshness and fulness of tone of the instrument.

TRU′MPETER, a soldier in a cavalry regiment, whose duty it is to re-pronounce or pass on the orders of the commanding officer; for which purpose certain recognised simple tunes have arbitrary meanings attached to them.

TRUMPET-FISH, or SNIPE-FISH (*Centriscus*), a genus of fishes of the family *Fistularidæ*, remarkable for the elongated and tubular snout. The



Trumpet-fish (*Centriscus scolopax*).

only British species (*C. scolopax*), rare on the British coasts, but abundant in the Mediterranean, attains a length of about five inches, the snout projecting about an inch and a half in front of the eyes. The mouth is destitute of teeth. This little fish is esteemed a delicacy, and is often to be seen in the markets of Italy.

TRUMPET FLOWER, the popular name of certain flowering shrubs of the genera *Bignonia* and *Tecoma*, both of the natural order *Bignoniaceæ* (q. v.). *Bignonia capreolata* is a native of the southern states of America, but often planted in shrubberies and gardens in the middle states. It is a climbing shrub with conjugate leaves and heart-shaped oblong leaflets. The flowers are reddish-yellow, with a long tubular corolla, from the form of which the English name is derived.—*Tecoma radicans* (formerly *Bignonia radicans*) is also a climbing shrub, and a native of the southern states of America, reaching to a more northern latitude than the last. It has much larger flowers, of a scarlet colour. The leaves are pinnate, the leaflets ovate and toothed.—*T. grandiflora* is a native of Japan, with pinnate leaves and flowers much larger than *T. radicans*. Both are cultivated with success in the open air in England.

TRU′NNION. See GUN.

TRU′RO, a municipal and parliamentary borough and seaport of Cornwall, of which county it is considered the metropolis, though Bodmin (q. v.) is the county town, 8 miles north-north-east of Falmouth. It stands at the junction of two rivers, the Allen and the Kenwyn, which are here met by an inlet of the sea called the Truro river, the banks of which present some beautiful scenery, and which admits of vessels of 100 tons burden passing upward to the quays of the town. T. is the centre of a mining district, and largely exports tin and copper ore. St Mary's Church, a Perpendicular edifice of the reign of Henry VII., is the principal building. Pop. (1881) 10,663.

TRUSS, an instrument employed in the palliative treatment of Hernia (q. v.), with the view of preventing its descent, and, in some cases, of effecting a permanent cure. It consists essentially of a pad or cushion attached to a metallic spring, with straps so arranged that its position may be retained during the varied postures of the body. The necessity of having recourse to a suitable truss the moment that the slightest protrusion shews itself in any of the parts liable to hernia cannot be too strongly urged as a matter of necessary general knowledge. At whatever period of life a hernia occurs, if properly attended to, and judiciously supported, it usually gives little trouble, and if it occurs in early life, it may often be cured; whereas, if it be neglected, increase of bulk, and subsequently, diseased states of the parts, often terminating in death, will almost certainly occur. A surgeon should always be consulted in the choice of the instrument. 'The practice,' says Mr Birkett, 'of leaving cases of rupture in the hands of mere tradesmen cannot be too strongly censured. Amongst the poor, we constantly observe the lamentable effects of this proceeding.' Many varieties of trusses have been invented. Mr Kingdon, surgeon to the City of London Truss Society, considers that the 'circular spring truss' is the most suitable form in the majority of cases. There are occasional cases in which the common truss fails to support a rupture comfortably, and in these cases various instruments, for the most part the property of special instrument-makers, are often serviceable; and the surgeon should be acquainted with the peculiarities of the pieces of apparatus known as the Mocmain Lever Truss, Coles's Truss (with a spiral spring acting on the pad), Salmon and Ody's Self-adjusting Truss, Eggs's Truss, &c. The patient must expect to find the truss somewhat uncomfortable for a week or two, but will soon get used to it. The skin of the part upon which it presses should be regularly washed and bathed with Eau de Cologne, or spirit, as, without this precaution, boils are apt to form on it.

TRUSS. See CONSOLE. Also the framework, composed of tie-beam, rafters, struts, &c., forming one of the principal supports of a roof.

TRUSSING, in Ship-building, diagonal timbers or iron plates crossing the ribs internally, and consolidating the whole together. Iron is preferred to wood, as being less heavy and less bulky.

TRUST, in the Law of England, is a confidence reposed in some other person touching land or goods for which the *cestui que trust*, or beneficiary, has no remedy except in the Court of Chancery. In more popular language, it means a species of divided proprietorship, whereby the trustee acts as a custodier or strong-box; and yet the benefit of the property is not his, but belongs to the *cestui que trust*. The person who creates the trust is sometimes called the *celui que trust*. As a general rule, all property, whether real or personal, may be made the subject of a trust, provided some policy of the law or statute does not prevent it. Trusts are most frequently created by a will; but they may be declared by word of mouth as regards personalty, while as to land, some writing is necessary. No particular words are necessary, but the intention of the party making the trust must be clear. Thus, in wills, a testator sometimes uses words which do not amount to an express trust, but speaks of his 'wish and desire,' or his 'confidence,' that the executor or trustee shall do certain things. These words are called in the law precatory trusts, but are enforced

in the same way as more direct language, if no uncertainty exists as to the purposes or mode of carrying out the trust. But if a testator merely recommends an executor to 'consider certain persons,' 'to be kind to them,' or 'to do justice to them,' or 'to make ample provision for them,' &c.—such expressions are treated as too vague to be binding, and therefore the executor may disregard them, or use his own discretion. A trustee's is not a compulsory office, but gratuitous, and therefore he need not accept the office unless he pleases. But if he once accept, he is not at liberty afterwards to renounce, unless the trust-deed contain a provision enabling him to do so, or the Court of Chancery for good reasons discharge him. A trustee cannot delegate the office to a third person, but continues personally bound to do his duty. Where there are several trustees appointed, the office is considered joint, so that if one dies, the survivors continue to exercise the office. As a general rule, all must join in doing any act; but if the trust is of a public nature, a majority may bind the minority. Each trustee is liable only for his own acts or defaults, and this is so even though, for form's sake, he join his co-trustees in signing a receipt, if he can shew that he never received the money in point of fact. Nevertheless, when money lies in the hands of one trustee, the others ought not to be satisfied with his mere statement that the money has been invested by him, but should see that it is actually done. Another rule is, that a trustee is not allowed to make a gain of his office; and so jealous is a court of equity of this rule, that the trustees of a large estate are not even allowed to sport over the estate—at least so as thereby to keep any valuable right of that kind for their own pleasure. Hence, a trustee is personally liable if he trade with the trust funds, or buy shares in a joint-stock bank; for even though the trust-deed authorise this to be done, he will be liable to pay the debts of the trading concern, though far exceeding the amount of the trust funds. So, if a trustee is a solicitor, and does legal business for the estate, he will not be allowed to charge for his professional labours, but at most will be allowed only the costs out of pocket. It is seldom, therefore, that a trustee can get any benefit to himself from the trust estate, except in the rare case where the *cestui que trust* is dead without heirs, in which case the property will become the trustee's. This is, however, only so as to real estate; for if the trust estate consist of chattels, then, on the death of the *cestui que trust* without heirs or executors, the property goes to the crown, and not to the trustee. It is the duty of a trustee to keep the trust funds safe; and if they consist of moneys, then he ought to invest them in government stock, and not let the money lie unproductive. He is not entitled to lend the money on personal security, or in the shares of any private company; but he may invest in mortgages, unless he is forbidden by the deed or will. If there is, therefore, no power to invest in mortgages, the trustee must invest in three per cent. consols, and a few other government securities. The trustees, as a general rule, must pay interest whether they invest the funds or not (if they have had time to invest) to the *cestui que trust;* and they must account for all the profits they make with the trust funds, whether rightly or wrongfully. If a trustee has grossly misconducted himself as to the trust funds, he will be charged five per cent. interest, and sometimes with compound interest. A trustee is entitled to be indemnified for all the reasonable expenses or outlay attending the execution of the trust, but he must in general bear the loss of any mistake as to the law; but if there is any peculiar difficulty in carrying out the trust, he is entitled to take the opinion or, or even to throw the chief management upon, the Court of Chancery, as the only safe protection. When trustees are guilty of gross negligence, mismanagement, or misconduct, the Court of Chancery will remove them, and appoint others.—In Scotland, there are several technical points of difference from the above in the law of trusts.—Paterson's *Comp. of English and Scottish Law*, s. 201. The chief practical difference is, that the investment of the trust funds in heritable securities or mortgages, is considered equivalent or superior to government security, and hence it is the duty of the trustees to prefer such securities, as, owing to the practice of registration of deeds affecting real property, heritable security is always a safe investment there.

TRUXI'LLO, a town of Spain, province of Cáceres, on the great highway from Madrid to Badajoz, and 80 miles north-east of the latter place, is built on a granite knoll, and is an old decaying town; but rising as it does in terraces from the road, it presents, at a little distance, rather a picturesque and imposing appearance. There are several churches and convents here. Pop. 6000, who are engaged chiefly in agricultural work. T. is the birthplace of Pizarro, who was also buried here in the church of Santa Maria de la Concepcion.

TRUXILLO, a town of Peru, province of Libertad, near the sea-coast, about 520 miles north-north-west of Callao. The port of T. is Huanchaco, about eight or nine miles to the north-west, from which considerable quantities of rice and spices are exported. Pop. 5000. T. was founded in 1535 by Pizarro, who named it after his birthplace in Spain.

TRYGON. See STING RAY.

TRYSAIL, a small fore-and-aft sail, mounted by

Trysail (*a*).

a cutter or schooner in a storm, when the wind is too violent for her to carry her ordinary canvas.

TSA'RSKO SE'LO (i. e., Imperial Town), a town of Russia, in the province of St Petersburg, and 13 miles south of the city of that name. It is the royal residence and favourite resort of the imperial family. The carriage-road from the capital to this town was constructed by the Empress Catharine at a cost of 1,000,000 rubles; but the *route* now preferred is that of the railroad—the first laid down in Russia. The façade of the great palace of T. S. is 1200 feet long. Originally, every statue, pedestal, and capital of the columns, vases, &c., was covered with gold leaf; only the dome and cupolas of the church are now gilded. The interior of the chapel is lavishly gilded, the ceiling being one sheet of gold.

There are several elegant rooms, though most of them are more remarkable for barbaric splendour than for taste. In the palace grounds, which are 18 miles in circumference, is an arsenal, containing a magnificent collection of armour, weapons, and accoutrements of all kinds. The imperial family no longer reside in the palace, but in a large building in the park. Pop. (in the year 1866) 10,173.

TSCHUDI, an ancient and noble family in the Swiss canton of Glarus, several members of which have distinguished themselves as authors, statesmen, and warriors. The two following are the most notable of the Tschudi. GILLES, or AEGIDIUS (born 1505, died 1572), who was active on the Catholic side during the struggles of the Reformation in Switzerland, and in consequence was forced for a time to leave his native canton (1562), but was permitted to return two years afterwards. He was a prolific writer, not less than 166 works of his, in print or in MS., being known. The most valuable is a *History of Switzerland* (Basel, 2 vols. 1734). See Fuch's *Aegid. Tschudi's Leben und Schriften* (2 vols., St Gall, 1805). To the same family belongs JOHANN JAKOB VON T., the eminent traveller and naturalist, born at Glarus, 25th July 1818. After completing his studies at Leyden and Paris, he undertook (1838) a voyage round the world; but circumstances restricted his design to an investigation into the natural history and ethnography of Peru, where he remained for five years. On his return to Europe (1843), he wished to join the Arctic expedition of Sir John Franklin, but was again prevented by circumstances from doing so, and finally settled as an author on his estate near Wiener-Neustadt, in Lower Austria. T.'s principal works are: *Peru: Reiseskizzen aus den Jahren* 1838—1842 (2 vols., St Gall, 1846); *Untersuchungen über die Fauna Peruana* (St Gall, 1844—1847, with 76 plates); the splendid work, *Antiguedades Peruanas* (Vien. 1851), executed in conjunction with Don Mariano Eduardo de Rivera, and which has been translated into English by the Rev. F. L. Hawks (New York, 1854); and *Die Kechuasprache* (2 vols., Vien. 1853), containing a grammar and dictionary of the Peruvian language.

TSETSÉ (*Glossinia morsitans*), a dipterous insect, which is a terrible pest of some parts of South Africa. It is not much larger than the common house-fly, of a brown colour, with four yellow bars across the abdomen. The wings project considerably beyond the abdomen. It is remarkably alert, at least during the heat of the day, and dexterously avoids any attempt to catch it with the hand. 'Its peculiar buzz,' Livingstone says, 'can never be forgotten by the traveller whose means of locomotion are domestic animals.' Its bite is almost certain death to the ox, horse, and dog. Livingstone, in one of his journeys, lost forty-three fine oxen by it. Yet the bite is harmless to man, to the mule, the ass, and apparently to antelopes and the other wild animals of the country. The proboscis is adapted for piercing the skin, and the fly lives by sucking blood. At first, no effect is perceived; but in a few days after an ox has been bitten by the T., the eyes and nose begin to run, 'the coat stares as if the animal were cold,' a swelling appears under the jaw, and sometimes at the navel, emaciation and flaccidity of the muscles ensue, purging, sometimes staggering and madness, and finally death. On dissection, the cellular tissue under the skin is found to be injected with air, as if a quantity of soap-bubbles were scattered over it.—Livingstone's *Travels*.

TSONG-KHA-PA (orthographically, *b*Tsong kha pa*) is the great reformer of Lamaism (q. v.), who, by his co-religionists, was considered to be an incarnation of the Bodhisattwa Amitâbha, or, according to others, of Manjus'rî or Vajrapân'i, and after his death, was canonised by the Lamaist Church. He was born in the middle of the 14th c. after Christ, in the country Amdo, in the place where now the celebrated convent *ss*Ku'bum is situated. According to the legends of Tibet, he was conceived by his mother in a supernatural, immaculate manner: he was born with a white beard, and from the day of his birth expressed himself clearly and fluently, and discoursed profoundly on religious matters. In his third year, he resolved to renounce the world. His mother accordingly cut off his long beautiful hair; but when it fell to the ground, a tree grew up—which is still in a court-yard of the convent of *ss*Ku'bum, and was seen and described by the missionaries Huc and Gabet, in the year 1845. The leaves of this tree are covered with one or more letters of the sacred Tibetan alphabet. He now lived retired from the world, entirely devoting himself to prayer and contemplation. A learned Lama from the West, 'with a long nose and bright eyes,' came to settle about this time in Amdo, and seems to have become his teacher. After his death, T. set out to Tibet, and travelled until he came near Lhassa, where a god bade him halt. Here he studied assiduously the Buddhistic law, and soon became convinced of the necessity of reforming the actual worship and discipline of the Lamaist Church. When his teaching attracted a great number of pupils, and when these, in order to distinguish themselves from the followers of the old system, who wore a red cap, assumed as their mark a yellow cap, the head of the Lamaist Church resolved to stop the innovator in his dangerous course, and accordingly summoned him to his presence. But T. did not deign to obey his command. Thereupon, the great Lama repaired in person to the bold monk; but when he entered the cell of T., his red cap fell off—and when he began to descant on the superiority of the old system, T.—seated and turning the beads of his rosary—without raising his eyes, cried out: 'Miserable! I hear the groans of a creature whom thou murderest!' And, in fact, unmindful of the first commandment of the Buddhist law, the great Lama was busy crushing a louse which he had caught. Confused, he fell at the feet of T.; and from this moment no further resistance could be made to his reforms. Such is the legend; but independently of it, history tells us that the influence which T. exercised on the reform of Lamaism, though not miraculous, was very powerful, such as to reduce the wearers of the red cap to a small minority. His reputation having widely spread, thousands of pupils thronged round him to hear and to adopt his doctrine. In consequence, in 1407 or 1409, he founded the convent *d*Ga' *l*Dan; and when this could no longer contain the number of his adherents, two other convents, which, together, it is said, are now peopled with 30,000 monks of the yellow cap. His works are numerous and voluminous; the most celebrated of them is the *Lam nim ch hen po*, or, 'The great Step-road towards Perfection,' consisting of three parts, namely, 'the road of the little, middle, and great man.' The sect which he founded, and which adopted the yellow cap, is called *d*Ge lugss pa, or the sect of virtue; and the principal reforms which he introduced into the Lama religion as it then existed, were compulsory celibacy for the monks—the Lamas of the old doctrine being conditionally permitted to marry—prohibition of sorcery

* The small letters prefixed to the initials of the Tibetan words in this article are not pronounced

and necromancy—which were extensively practised by the wearers of the red cap—and the institution, at fixed periods, of religious exercises and of common prayers, and, consequently, of regular meetings of the whole community. His greatest achievement, however, was the organisation of the Lamaist hierarchy as it still exists. See LAMAISM. He died in 1419. His body is preserved in the convent *d*Ga' *l*Dan: it is free from decay; and, like the tomb of Mohammed at Medina, suspended in the air without any support. His portrait is seen in all the temples of the yellow religion, often between those of the two Lamaist popes, of whom the *Dalai Lama* is at his right, and the *Pan chhen Rin po chhe* at his left. He is recognisable by two lotus flowers which he holds in his hands, folded for prayer, and one of which usually carries in its calix a candle, while the other supports a book. His canonical name is *b*Lo *b*Sang graggs pa, or 'the Celebrated Sage.'—See for further detail, C. F. Koeppen, *Die Lamaische Hierarche und Kirche* (Berlin, 1859), and the works quoted there.

TU'AM, an inland market-town and episcopal seat, as well as centre of a poor-law union, of Galway, Ireland, is situated on the Harrow, a branch of the Clare, 125 miles west from Dublin, with which it is connected by a branch from the Midland Great Western Railway. The pop. in 1871 was 4938, of whom 4280 were Roman Catholics, and the rest Protestants of the Established Church and of other denominations. It has been an archiepiscopal see since the 12th c., and continues to have this rank in the Roman Catholic Church; but in 1839, the province was united in the Established Church with the archbishopric of Armagh, of which T. is now a suffragan see. The town possesses little trade, except in agricultural produce; but there are some tanneries, a flour-mill, and a brewery. The Roman Catholic church, which is a modern structure, is of great size, and of very striking architecture. Both the Roman Catholic archbishop and the Protestant bishop have residences in T.; and under the direction of the former is the college of St Jarlath, numerously attended, but designed chiefly for clerical students. The municipal affairs are under the direction of commissioners. The schools, which are under the care of the brethren of the Franciscan Order, are numerously attended.

TUARIKS. See BERBERS.

TUBER, in Botany, a subterranean stem, thickened by the approximation of the nodes and swelling of the internodes, with latent buds along its sides ready to produce new plants in the succeeding year. The cellular tissue is unusually developed, and in general a large quantity of amylaceous matter is accumulated, whence the economical value of tubers, as in the potato, the Jerusalem artichoke, and the arrow-root. Tubers are capable of being employed for the propagation of the plant, by division into portions, each containing an *eye* or bud, according to the usual mode of planting potatoes. Like bulbs and corms, they may be regarded as a store laid up for the plant itself, that it may spring with new vigour in a new year. Like them, also, and even in a greater degree, they are in many cases a provision for the use of man. The most valuable tubers are those already named, but many others are used in different parts of the world. See OXALIDEÆ, TROPÆOLUM, &c.

TU'BERCLE is a word that has been employed by pathologists of different epochs in very different senses. The older writers employed the term merely to express an external form; and everything was called a tubercle which manifested itself in the form of a small knot. Without entering into any discussion of the views of Laennec (who asserted that tubercle presented itself in the lungs under two different aspects—namely, as *tubercular infiltration* and *tubercular granulation*, and thus opposed the old knot-theory), of Lebert (who was the first accurately to describe the so-called 'tubercle-corpuscles'), of Reinhardt (who, with many others, holds that tubercle is nothing more than one of the forms presented by inflammatory products when undergoing transformation, and that all tubercular matter is really inspissated pus), or of Rokitansky, Van der Kolk, Williams, Walsh, Paget, and other eminent pathologists, we shall briefly give the theory of tubercle which Virchow adopts in his *Cellular Pathology*, and which is perhaps more generally adopted than any other. Virchow holds that tubercle is a granule or a knot, and that this knot constitutes a new formation, which, from the time of its earliest development, is necessarily of a cellular nature, and like all other new formations, has its origin in connective tissue. When this new formation has reached a certain degree of development, it constitutes a minute knot; and if it is near the surface it forms a little protuberance, its mass consisting of small nucleated cells. The great characteristic of this formation is its extreme richness in nuclei, of which, at a first glance, it seems entirely to consist. But upon isolating the constituents of the mass, either very small cells with a single nucleus are seen, or larger cells with twelve, twenty-four, or even more divided nuclei are observed, these nuclei being always small, and having a homogeneous and somewhat shining appearance. In the accompanying figure (magnified 300 diameters), the whole succession of transitions is seen from the simple connective-tissue corpuscle, the division of the nuclei and cells, up to the production of the tubercle-granule, the cells of which, in the middle, are disintegrating into fatty granular *débris*. In its minute nuclei and very small cells, it contrasts strongly with the large and comparatively gigantic corpuscles of some of the more highly organised forms of cancer. To use the expressive language of Virchow: 'Tubercle is always a pitiful production, from its very outset, miserable.' For an account of the *Cheesy Metamorphosis* which subsequently characterises the tubercle, and which is the regular but not the invariable termination of this formation (since tubercle *may* undergo a complete fatty metamorphosis, and become capable of absorption, or may undergo calcareous degeneration, in which form it remains comparatively inert), we must refer to the above-named pathologist's *Cellular Pathology*, translated by Chance (Lond. 1860), to Rokitansky's *Morbid Anatomy*, vol. i., and to Paget's *Surgical Pathology*.

Tubercle.

Tubercle is usually described as occurring in two principal forms, the first being distinguished as the yellow, and the latter as the gray; the latter is also known from its ordinary size as the miliary

tubercle. The latter is the tubercle to which the above description of Virchow applies, the yellow being the same in a state of fatty degeneration or cheesy metamorphosis. In consumption, we often find large masses of softening tubercular matter in the lungs and elsewhere. These large masses are formed by the aggregation of smaller masses, which have coalesced as the deposit continued to increase. The intervening tissues at length suppurate, and thus soften and break down the tubercular matter, and lead to its expulsion; for a process of ulceration having been established into the surrounding tissues, the softened tubercle is brought up by coughing, and a cavity or *vomica* is formed at the spot previously occupied by the morbid deposit. It is a remarkable fact, and one of the greatest importance in the diagnosis of consumption, that tubercles, when they affect the lungs, are almost invariably deposited in the upper lobes. When it is stated that consumption is only one manifestation of Scrofula (q. v.), and that tubercle is the essential element of scrofula, it will be seen that the importance of this subject cannot be overrated. On this subject, the reader may with advantage consult the late Mr Ancell's elaborate volume *On Tuberculosis;* or a clever essay, with a similar title, recently published by Dr Dobell.

TU'BEROSE (*Polianthes*), a genus of plants of the natural order *Liliaceæ*, having a funnel-shaped perianth, with 6-parted limb, stamens inserted in the tube of the corolla, a superior capsule, and flat seeds. The COMMON T. (*P. tuberosa*) has rounded bulbous roots; a cylindrical, upright, unbranched stem, three or four feet high; both root-leaves and stem-leaves sword-shaped, and very acute; flowers spiked and somewhat aggregated, large, pure white, the tube a little curved. The plant grows well in the south of Europe, but only bears the open air in more northern climates during summer. The roots are a considerable article of export from the south to the north of Europe; the plant being in high esteem for the beauty and fragrance of its flowers, the odour of which is most powerful after sunset, and has been known to cause headache and asphyxia in a room. The fading flowers emit, in certain states of the atmosphere, an electric light and sparks. The flowers yield an essential oil, which is used by perfumers. The native country of the T. is not quite certain. Another species, *P. gracilis*, is found in Brazil, and has been supposed to be the original of the cultivated plant.

TUBE-WELL. See SUPPLEMENT in Vol. X.

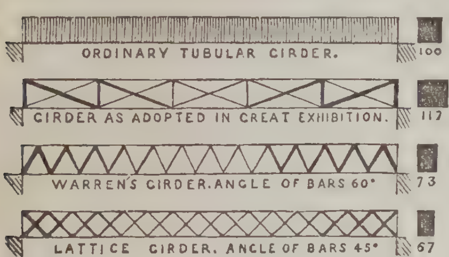
TUBI'COLÆ, an order of *Annelida* (q. v.), having a tubular shelly covering, into which the animal can entirely retreat, but from which, when undisturbed, and disposed to activity, it projects its head and gill-tufts. The genus *Serpula* (q. v.) is a good example.

TUBICO'LIDÆ, or GASTROCHÆ'NIDÆ, a family of lamellibranchiate molluscs, remarkable for the calcareous tube into which the proper shell is cemented. Examples are noticed in the articles ASPERGILLUM, CLAVAGELLA, and GASTROCHÆNA. The *Pholadidæ*, including Pholas (q. v.) and Teredo (q. v.), are included by some in this family. *Teredo* has the characteristic tube, but *Pholas* has not.

TÜ'BINGEN, an important town of Würtemberg, in the Circle of the Black Forest, 20 miles south-south-west of Stuttgart, is situated on the Neckar, at the influx of the Steinlach, in one of the most beautiful and fertile districts of the Oberland. T. is an old place, irregularly built, with steep and narrow streets in the main; but the suburbs, especially round about the new university, are very pleasant. Westward from T. is the Schloss, built by Duke Ulrich in 1535. Book-printing, bookselling, working in copper, weaving, bleaching, trading in field-produce, wine, and fruits, form the principal sources of employment. T. has three Protestant churches and one Catholic church, a Bible Society, a Chamber of Manufactures, and various educational and benevolent institutions. But it owes its celebrity wholly to its university. Founded in 1477 by Eberhard im Bart, afterwards first Duke of Würtemberg, the university of T. soon became a distinguished seat of learning, enjoyed for a time the presence of Reuchlin (q. v.), and Melanchthon (q. v.), and continued to flourish long after the Reformation had firmly established itself. The Thirty Years' War, however, fatally checked its prosperity; and it was not till the early part of the present c. that it began to reacquire a reputation. Under Baur (q. v.), it has recently become celebrated as a school of historico-philosophical theology, known as the 'Tübingen School,' the influence of which on the development of religious thought has been very great, and is likely to prove permanent. The university has 6 faculties, 41 ordinary and 12 extraordinary professors, a library of 150,000 vols. (located in Duke Ulrich's *Schloss*), and was attended (1862—1863) by 678 students, of whom nearly 100 were foreigners. Connected with it are an anatomical and physical institute, a botanical garden, a chemical laboratory, a collection of zoology and comparative anatomy, one of minerals, one of coins and antiquities, fencing, gymnastic, and swimming schools, &c. Pop. of T., in 1880, 11,839.

TU'BULAR BRIDGE. The advantages of the tube for carrying a level roadway across a large span were brought into general notice by Robert Stephenson, engineer of the Chester and Holyhead Railway, in the construction of the bridges to carry that railway across the Menai Strait. It was required by the Admiralty, that these bridges, called the Britannia and Conway, should be constructed, so as not to interfere with the navigation, with clear spans of upwards of 400 feet. The largest arched spans that had been previously constructed did not exceed 240 feet; and suspension-bridges not being suitable for heavy and rapid railway traffic, the engineer was obliged to devise some new form, which should conform to the stipulated conditions. Mr Stephenson having decided upon the tubular form, proceeded, in conjunction with Mr Fairbairn, to make an elaborate series of experiments on tubes, to determine the most suitable arrangement of the wrought iron of which they were to be composed. They found that a rectangular tube, of which the top and bottom were cellular (as in fig. 7, article STRENGTH OF MATERIALS), gave the greatest strength with the least material. The span of the Conway tube was 400 feet; while the tubular part of the Britannia Bridge consisted of two spans of 460 feet, and two of 230 feet each in the clear. The foundation-stones of these bridges were laid in 1846 and 1847 respectively. Since that time, many important bridges have been constructed on this principle. One of the largest and most important is the Victoria Bridge, over the St Lawrence, near Montreal, in Canada. The total length of this bridge is 9144 feet, or nearly 1¾ mile. It is built in 24 spans, of from 242 to 247 feet each, and one of 330 feet. The greatest depth of the river is 22 feet, and the average rate of the current 7 miles per hour. The bottom of the centre tube is 60 feet, and at the abutments the bottom is 36 feet above the water, so that there is a rise of 1 in 130 in the roadway towards the centre of the bridge. An idea of the stupendous nature of this structure may be formed from the facts, that 9000 tons of iron were used in the tubes, and 1½ million of rivets; also that the total surface of iron was 32 acres; and as it received 4 coats of

paint, the total painting was 128 acres. There were 2,713,095 cubic feet of masonry, and 2,280,000 cubic feet of timber in the temporary works, dams, &c.; and upwards of 3000 men were employed. The first stone was laid on July 20, 1854, and the first train passed over on December 17, 1859. The total cost was £1,400,000, or about £57 per lineal foot. Notwithstanding the success of these structures, the tubular form has been to a great extent superseded in recent structures by the lattice or trellis. This has arisen from the great saving in the material of which the sides are composed, effected by the open lattice-work, as compared with the solid plated side of the tube. By the lattice arrangement, the material is more capable of arrangement in the direct line of the strains; and the section of the lattice-bars can be accommodated to the strain, so that there shall be no material which is not carrying its due share of the load. The first large structure of this nature was the Boyne Viaduct, on the Dublin and Belfast Junction Railway. Mr Barton, the designer of this structure, in a notice of this bridge, gives the relative weight in the sides of different forms of girders, neglecting the weights of the top and bottom, which are the same in every case, as follows:



Besides this considerable saving in material, the facilities this form gives for repairs and painting, and the exposure of a smaller surface to the wind, are additional reasons for its preference.

TUBULIBRANCHIA'TA, an order of gasteropodous molluscs, having two branchiæ behind the heart, the whole animal enclosed in a long shelly tube, which is sometimes straight, sometimes twisted in an irregularly spiral manner.

TUCKER, Abraham, an English author whose reputation falls far short of his merits, was born in London, September 2, 1705, studied at Merton College, Oxford, and in 1726 became a member of the Inner Temple. T., who was of good family, inherited a large fortune from his father; and in 1727 purchased Betchworth Castle and estate, near Dorking, in Surrey. During his life, he enjoyed all the ease, comfort, and quiet happiness of an English gentleman of the 18th century. It is but fair to state that his frank, generous, virtuous nature, and his sincere love of intellectual pursuits, prevented him from misusing the advantages of his position. In 1736, he married Dorothy, daughter of Edward Barker, Esq.—afterwards Cursitor Baron of the Exchequer, and Receiver of the Tenths—by whom he had three daughters, the youngest of whom, Dorothy Maria, became, in 1763, the wife of Sir Henry Paulet St John, Bart. T.'s affectionate regard for his family is a beautiful feature of his character. He was, too, all his life, an industrious student, a man of keen observation, of much innocent and cheerful humour, and withal, of methodical business habits. His death occurred November 20, 1774. T.'s great work is entitled *The Light of Nature Pursued*. It was begun in 1756, and formed the chief literary occupation of the rest of his life. It extended to seven volumes, only three of which were published in the author's lifetime, under the pseudonym of Edward Search, Esq. It is not a regular systematic treatise, but consists of a series of disquisitions on metaphysics, theology, morals, &c., all of which exhibit a remarkable originality, simplicity of humour, ingenuity of illustration, and solidity of understanding. Scarcely any English book of the 18th c. is more deserving of study, and scarcely any has been more neglected. A critic in the *Saturday Review* (November 12, 1864) has given an intelligent appreciation of its peculiar merits. The best edition of *The Light of Nature* is that published by the author's grandson, Sir Henry Mildmay, reprinted in 1837. A later edition is that by the Rev. Dr Cairns of Berwick.

TUCU'M and TUCUMA' PALMS. See Astrocaryum.

TUCUMA'N, San Miguel de, a town of La Plata, capital of the province of the same name, about 120 miles north-west of Santiago, is embosomed in splendid plantations of fruit-trees. T. has a cathedral, convents, a Jesuits' college, and many handsome houses. It carries on manufactures of sugar, leather, and brandy, has an active trade in oxen and mules; and the females are noted throughout the Confederation for their skill in making saddle-cloths. Pop. 11,000. Here, in 1816, a congress of deputies from the various Argentine provinces met, and proclaimed their independence of Spain.

TUDE'LA (the *Tutela* of the Romans), a city of Spain, province of Navarra, on the left bank of the Ebro, which is here crossed by a bridge of 17 arches, 46 miles by railway north-west of Saragossa. It is a dull, gloomy-looking place, with narrow streets and lofty houses; but the promenades along the river are very fine, as also are the *plazas*, or public squares. T. is the seat of a bishop, has a Gothic cathedral, a medical college, and manufactures of coarse woollen cloths, soap, earthenware, &c., and carries on an active trade in the products of the district. Pop. 8900.

TUDOR, the surname of a family of Welsh extraction, which occupied the throne of England from 1485 to 1603. In the Welsh language, Tudor is the equivalent of Theodore. Owen Tudor, the first of the race known in history, has had a pedigree assigned him from the ancient Welsh princes, which rests on no very solid evidence. In fact, little is known of his origin, except that his father had to quit Wales on a charge of murder, and was outlawed. He seems himself to have been at one time a brewer at Beaumaris, in Anglesey; and he was afterwards a retainer in the suite of the Bishop of Bangor, and fought at Agincourt. His dancing at some court pageant is said to have first ingratiated him with Catharine of Valois, widow of Henry V., who appointed him to the office of Clerk of the Household, and before long entered either into an illicit connection or a private marriage with him. The indignation of the public at this step obliged the queen to take refuge in a convent at Bermondsey, where she died; and Tudor was sent to Newgate, but succeeded in escaping, and obtaining two audiences of the young king, Henry VI., who afforded him protection, and conferred on him the lieutenancy of Denbigh. Two sons had been born to him by the queen. On the elder, Edmond, the king bestowed the earldom of Richmond; and on the younger, Jasper, the earldom of Pembroke. The Earl of Richmond married Margaret, daughter and heiress of John Beaufort, Earl of Somerset, whose father was an illegitimate son of John of

Gaunt by Katherine Swynford. The sole issue of Richmond and the heiress of Somerset, Henry, Duke of Richmond, invited from abroad to deliver England from Richard III., ascended the throne after Richard's death at Bosworth as Henry VII. The partisans of the House of Lancaster supported him on the extinction of the lawful descendants of John of Gaunt; and by his marriage with Elizabeth, eldest daughter of Edward IV., and representative of the House of York, he was considered to have united the factions of the White and Red Rose. Five sovereigns of the House of T. successively occupied the throne—viz., Henry VII., Henry VIII., Edward VI., Mary, and Elizabeth—for an account of whom see separate articles. From Elizabeth, the last of the line, the crown passed to James VI. of Scotland, of the House of Stuart, in virtue of his descent from Margaret Tudor, daughter of Henry VII., and queen of the Scottish James IV. Strength of will was the prominent characteristic of the sovereigns of the House of T.; their rule, generally prosperous, was far more arbitrary and despotic than that of the Plantagenets. Parliament was in many cases but the exponent of the royal will, and taxes were frequently exacted, and penal statutes dispensed with, by the prerogative alone. The condition of England under the Tudors differed from despotic monarchies chiefly in the important respect that the sovereign had no standing army. The T. monarchs exercised a remarkable influence on ecclesiastical affairs; it was under their rule that the Reformation took place, and the Anglican Church was developed.

TUDOR STYLE, in Architecture, a rather indefinite term applied to the late Perpendicular, and the transition from that to Elizabethan.

TUESDAY, the third day of the week, is so called from *Tiwesdæg*, the day of Tiw or Tiu, the old Saxon name for the god of war. See Tyr. The day bears a corresponding name in the other Germanic dialects.

TUFF, a rock formed from the ash or powder ejected from a volcano, mixed with the lapilli, or small fragments of lava. It may be arranged under the air, and remain quite loose, or be cemented by the percolation of water charged with mineral matter, by pressure or other cause. Sometimes the materials are arranged under water, and then the tuff contains organic remains, like other aqueous rocks.

TUILERIES, Palace and Gardens of the, are situated in the middle of Paris, on the right bank of the Seine, with Rue de Rivoli running along their north side, and Quai des Tuileries to the south. Here, in 1342, a certain Pierre des Essarts possessed a pleasure house, called the *Hôtel des Tuileries*, on account of its being built in a locality outside the city where there were several tile-works (*tuileries*). Francis I. bought this property from the Sieur de Villeroy, as a present to his mother, the Duchess of Angoulême. It was afterwards chosen by Catharine de' Medici as the site of a new palace instead of that of Tournelles, and the building was begun in 1566. Originally, the palace consisted of only the square structure in the middle; but was greatly enlarged by Henry IV., Louis XIII. and XIV., Napoleon I.; and it received still further improvements at the hands of the late emperor, Napoleon III.

Louis XIII. was the first sovereign who resided at the Tuileries. Louis XIV. only stayed there for a short time, and then established himself at St Germain; Louis XV. and XVI. lived at Versailles. In 1793, the National Convention held its sittings in the Tuileries; and when Bonaparte became First Consul, he chose it for his official residence. It was the imperial residence of Napoleon III., but was burned by the Commune in 1871.

TULA. See Toula.

TULA-METAL, a peculiar alloy, made of silver, with small proportions of copper and lead. It is manufactured at the imperial metal-works at Tula, or Toula, in Russia, and is used for making the celebrated Russian snuff-boxes, erroneously said to be made of platinum.

TULIP (*Tulipa*), a genus of plants of the natural order *Liliaceæ*, having an inferior bell-shaped perianth, of six distinct segments, without nectaries; a sessile three-lobed stigma, a three-cornered capsule, and flat seeds. The bulb is fleshy, and covered with a brown skin. About thirty species are known, mostly natives of the warmer parts of Asia. The name T. is supposed to be derived from the Persian name *Thouleban*, which also signifies a turban. The most famous of all Florists' Flowers is the Garden T. (*T. Gesneriana*), which is from 18 inches to 3 feet high, with a smooth stem, bearing one erect, large flower; the leaves ovate-lanceolate, glaucous, and smooth. The T. is a native of the Levant; it was brought from Constantinople to Augsburg by Conrad Gesner, in 1559, and was rapidly diffused throughout all parts of Europe. The varieties in cultivation are innumerable. The tulip mania of the 17th c. in Holland is noticed in the article Florists' Flowers. The T. is still most sedulously cultivated in Holland, especially at Haarlem, from which bulbs are largely exported. It is prized merely for the size and beauty of its flowers; its smell being rather unpleasant. Great attention is paid to the cultivation of tulips, not only in the gardens of the wealthy, but often in those of the humbler inhabitants of small towns and villages, in which beautiful beds of tulips may often be seen. Tulips succeed best in a light, dry, and somewhat sandy soil. Bulbs are planted in the end of October, or beginning of November, and the flowers are produced early in summer. Beds of choice tulips are protected in spring by hoops and mats; and in the flowering season an awning of thin canvas is spread over them, which greatly prolongs the duration of their beauty, as they are soon spoiled by exposure to strong sunshine. Tulips are propagated by offset bulbs, and new varieties are raised from seed.—Another species of T. cultivated in gardens is the Sweet-scented T., or Van Thol T. (*T. suaveolens*), which has a short, hairy stem, and yellow or red flowers, inferior to those of the common Garden T. in beauty, but prized for their fragrance, and for appearing more early in the season. It is often cultivated in pots in windows. It is a native of the south of Europe. The Wild T. (*T. sylvestris*), a native of many parts of Europe and Asia, is admitted into the British flora, but is a very doubtful native of Britain. It is common in the woods and vineyards of Germany and the south of Europe. It has a slender stem, narrow lanceolate leaves, and a somewhat drooping, fragrant, yellow flower. It develops offset bulbs at the end of fibres thrown out from the root, at some distance from the parent plant. Its bulbs are eaten in Siberia, although bitterness and acridity characterise the bulbs of this genus.

TULIP TREE (*Liriodendron tulipiferæ*), a beautiful tree of the natural order *Magnoliaceæ*, a native of the United States of North America, having a stem sometimes 100—140 feet high, and 3 feet thick, with a grayish-brown cracked bark, and many gnarled and easily broken branches. The

leaves are roundish, ovate, and 3-lobed; the middle lobe obliquely truncated. The flowers are solitary at the extremities of the branchlets; they resemble tulips in size and appearance. The bark has a bitter, aromatic taste, and like that of all the *Magnoliaceæ*, contains a bitter principle, called *Liriodendrin*. It has been used as a substitute for Peruvian Bark in

Tulip Tree (*Liriodendron tulipifera*).

intermittent fevers, and is a good tonic. The T. T, is one of the most beautiful ornaments of pleasure-grounds, wherever it grows and flowers well, which, however, in Britain, it does only in the southern parts. It is now plentiful in many parts of the south of Europe. In some parts of the basin of the Mississippi, it forms considerable tracts of the forest. The heart-wood is yellow, the sap-wood white. The timber is easily wrought, takes a good polish, and is much used for many purposes.

TULLAMO'RE, one of the capitals, and now the assize town of King's County, Ireland, also the seat of a poor-law union, is situated on the Grand Canal, 59 miles west-south-west from Dublin, with which it is connected by a branch from the Great Southern and Western Railway. It stands upon what may be called a fertile island of the great Bog of Allen, and has within the last half-century risen into some importance. The population amounted in 1881 to 5098, mostly Roman Catholics. It is a place of considerable business, commanding, from its central position, the inland traffic of a very large and not unfertile district. A large trade in corn and agricultural produce was formerly carried on with Dublin by the canal; but the repeal of the corn-law has of late years turned the agricultural industry into other channels. There is a large distillery, as also extensive breweries and several tanneries; and T. is the centre of a busy cattle-trade. The schools, both conventual and national, are excellent, and numerously attended. Within a few miles is situated the extensive Jesuit college of Tullabeg, which receives above 150 pupils.

TULLE, a town of France, dep. of Corrèze, at the embouchure of the Solane into the Corrèze, It is for the most part badly built, but has some fine promenades, excellent quays and bridges, a Gothic cathedral, an episcopal palace, a theological seminary, a communal college, an industrial college, a public library, and a theatre. One of the suburbs of T., called Souillac, is an imperial military manufactory, and the town is otherwise notable for its manufactures of leather, paper, cards, lace (known as *Point de Tulle*), liqueurs, and ironmongery. Some say that T. owed its origin to a Roman fort called *Tutela;* and in the vicinity are certain undoubted Roman remains; others, however, think it dates from the 4th century A. D. The population now numbers about 15,000.

TULLE, a kind of thin silk lace of a very open pattern and loose structure, usually in narrow widths for dressing ladies' caps, &c.

TUMBLER. See LOCK.

TUMBRIL, in an Army, a covered cart on two wheels, for the carriage of ammunition, tools, &c. belonging to the artillery. The name obtained a melancholy celebrity from being applied to the carts which served to carry the unfortunate victims of the French Revolution to the guillotine.

TU'MOURS do not admit of a satisfactory simple definition, but, in the words of Mr Paget, who has specially investigated this department of surgical pathology, they all belong to the class of over-growths or hypertrophies, and their most constant distinctive characters are—(1) that they are deviations both in respect to size and shape from the normal type of the body in which they are found; (2) that they have an apparently inherent power and method of growth; and (3) that their development and growth are independent of those of the rest of the body, continuing with no evident purpose when the rest of the body is only being maintained in its normal type.

Tumours are usually divided into two chief groups, known as innocent or benign, and malignant tumours. The characters of the latter are sufficiently discussed in the article CANCER, and we shall therefore restrict our remarks to innocent tumours. These may be divided into *cystic tumours*, or cysts, and *solid tumours;* while the latter are subdivided into the *discontinuous* and the *continuous;* the discontinuous being those which are completely invested with a layer of tissue, which at once isolates them and connects them with the surrounding parts, while the continuous ones appear as growths, not in, but of the surrounding parts, and appear as *outgrowths*, as, for example, many polypi, and pendulous or sessile tumours. In accordance with these ideas, Mr Paget classifies innocent tumours as follows: I. CYSTIC TUMOURS: CYSTS; which may be (*A*) *Simple* or *Barren*, or (*B*) *Compound* or *Proliferous*. (*A*) *Simple Cystic Tumours* include the varieties known as (*a*) serous, constituting what are termed hydromata, (*b*) synovial, (*c*) mucous, (*d*) sanguineous, (*e*) oily, (*f*) colloid, (*g*) seminal. (*B*) *Compound* or *Proliferous Tumours*, including (*a*) complex cysts, (*b*) cysts with glandular or other vascular growths, (*c*) cutaneous cysts, (*d*) dentigerous cysts. II. SOLID TUMOURS and OUTGROWTHS, including (*a*) fatty or adipose, (*b*) fibro-cellular, areolar, &c., (*c*) fibrous, fibro-muscular, (*d*) cartilaginous, (*e*) myeloid or marrow-like, (*f*) osseous, (*g*) glandular, and (*h*) vascular.

Of these various species we shall only notice a few of the most important. *Cutaneous cysts* may be congenital or acquired. They may be found under the skin of any part, but Mr Paget regards them as probably a hundred times more common in the scalp than in any other part. Their rate of growth is uncertain. When they grow rapidly, they are apt to ulcerate, and hence are derived most of the so-called 'horns' of the scalp and face.

Cutaneous cysts are usually formed either by the morbid growth of natural ducts or follicles, or by the enormous growth of elementary structures, which increase from the form of cells and nuclei, and become closed sacs with organised walls capable of producing other growths. A hair follicle or a sebaceous gland of its duct become obstructed, is thus often the origin of a cyst. Cutaneous cysts may be treated in various ways. Those in which the skin

over their chief prominence is marked with a small dark point, through which a fine probe may be passed into the cavity, may be gradually emptied by dilating their openings, and pressing out their contents; or they may be extirpated by caustic or the knife.

Fatty tumours are the most frequent of all innocent tumours, and are often described under the name of *lipoma* and *steatoma*. They do not differ materially in structure from the ordinary fat of the adjacent parts, and seldom cause much annoyance, except from their unseemly appearance. No good cause can be assigned for their formation, but they may sometimes be traced to a blow or friction, as of a strap. The age at which they most commonly shew themselves is at about forty. They may occasionally be absorbed by the prolonged internal use of liquor potassæ; but this treatment is almost certain to disturb the general health, and as a general rule, excision is the proper treatment. *Fibro-cellular tumours* are remarkable for the rapidity of their growth (three or four pounds in the year, and in one case recorded by Mr Paget, a pound a month), and the weight which they may attain (sometimes forty pounds or more). The most common seat of these tumours are the uterus, the scrotum, the bones, the subcutaneous tissue, the lobules of the ear, &c. Polypi of the uterus, nose, &c., belong to this class. Except in the case of polypi, excision is the only available remedy; and in some parts of the body this is of course impossible.

We will conclude with a reference to a remarkable class of cases which often sadly puzzle the inexperienced surgeon. They are known as *Phantom Tumours*, and are apparently due to contraction of the muscles. 'The abdominal muscles of hysterical women are most often thus affected; sometimes with intentional fraud. The imitation of a tumour may be so close as to require great tact for its detection, but chloroform, by relaxing the muscles, dissipates the swelling. Occasionally, these apparent tumours move.'—Paget on 'Tumours,' in Holmes's *System of Surgery*, vol. i., an article containing an excellent abstract of the most recent knowledge on the general subject of tumours.

TUMU′LTUOUS assemblages are, in point of law, in the category of riots, and were carried to an enormous height in the reign of Charles I. It was afterwards enacted by a statute of 13 Ch. II. c. 5, that not more than twenty names should be signed to any petition to the Crown or either House of Parliament for any alteration of matters established by law in church or state, unless the contents be previously approved by three justices or a grand jury; and no petition should be delivered by a company of more than ten persons. A later statute of 57 Geo. III. c. 19, made it unlawful to convene a meeting of more than fifty persons, or for more than fifty to meet in any street within a mile of Westminster Hall for the purpose of considering any petition or complaint to either House of Parliament for alteration of matters in church or state on any day when parliament is sitting. But the act does not apply to meetings to elect members of parliament. Other enactments were passed as to assemblies of persons collected under pretext of public grievances, but these were temporary, and have now expired.

TU′MULUS. See SEPULCHRAL MOUND.

TUN, a word which, under various modifications, exists in the Celtic and Teutonic languages, seems connected with the Latin *teneo*, I hold, or the Greek *teino*, I stretch, and signifies primarily a large vessel or cask. In various countries, Britain included, it denotes also a liquid measure of capacity; in old ale and beer measure, the tun was equal to 216 gallons (each gallon = 282 cubic inches), in old wine measure it was equal to 252 gallons (each gallon = 231 cubic inches). The tun and all other liquid measures of higher denomination than the gallon are no longer legal; but the names are, for convenience, still retained. These denominations had their origin in the natural practice of giving names to casks in common use which preserved a uniform size. As a tun of water weighs a little more than 2000 lbs., it is probable that the ton weight (see TON) was taken from the tun measure.

TU′NBRIDGE, a market-town in the county of Kent, stands on the Medway, on ground rising from the banks of that river, 27 miles south-east of London. The castle, which stands on the Medway, near the entrance of the town, dates from the close of the 13th c., has a noble gate-tower of great size, richly ornamented, and is at present occupied as a military training school. The parish church is a large and old, but sadly disfigured building; but the chief establishment of the town is the Grammar-School, of which the revenues are very considerable. Attached to it are 16 exhibitions of £100 a year, tenable at either university, besides 12 lesser exhibitions. The manufacture of toys and turned and inlaid articles of wood (see next article), is a specialty. Pop. (1881) 9340.

TUNBRIDGE-WARE, a pretty kind of manufacture in wood, carried on at Tunbridge Wells. It consists of small articles, such as ladies' work-boxes, ring-boxes, desks, &c., which are covered with a veneer characteristic of this industry; it is formed by building up a geometric pattern with very small strips of wood of a triangular or square shape in transverse sections; these are carefully glued together so as to form a solid mass, from which thin transverse veneers are cut, and are used to cover the articles made. This trade was formerly of much greater importance than at present.

TUNBRIDGE WELLS, a famous English inland watering-place, and after Bath, the oldest in the country, stands on the south border of Kent, 5 miles south of Tunbridge. The town, which is rapidly extending, occupies the head and slopes of one of the valleys of the Weald, and has in general a south-west aspect, commanding very fine views. The three centres of population are Mounts Ephraim, Sion, and Pleasant, separated by a large common and cricket ground. The waters are chalybeate. The Wells, discovered in 1606 by Lord North, are situated at the end of a promenade called the *Pantiles*. In the vicinity are charming rides and walks. The fashionable season is June, July, August, and September. Tunbridge-ware is also largely manufactured here. Pop. (1881) 24,309.

TU′NDRA (in Finnish, *Tuntur*—that is, mossy flat) is the Russian name for the vast plains which border on the Arctic Ocean in Siberia, and also westwards from the Ural along the north of Europe. They are swampy tracts of land, partly covered over with a thick felt of bog-moss, and partly with a dry snow-white covering of reindeer-moss and different kinds of lichens. It is only the reindeer that renders this frightful waste habitable for the wandering hordes of Samoyedes, who hunt the furred animals as well as the swans and wild geese which in summer flock hither in vast numbers. These polar steppes, however, can be trodden only in winter, when the whole region is one sheet of frozen soil and ice. In summer, when the surface thaws, the greater part of the region becomes an inaccessible morass, except a portion along the north coast of Siberia which retains its snow

covering throughout the year.—See Schrenk, *Reise nach dem Nordosten des Europ. Russland durch die Tundren der Samoyeden* 1837 (Dorpat, 1848).

TUNE, a short popular melody; also, that property of musical sounds by which they stand to each other in the relation of Pitch (q. v.).

TU′NGSTEN (symb. W, equiv. 184, sp. gr. 17·6) is a somewhat rare metal, which derives its name from the Swedish words *tung*, heavy, and *sten*, a stone. It is chiefly derived from Wolfram (whence the symbol W), which is a tungstate of iron and manganese, and likewise occurs in Scheelite, which is a tungstate of lime. It is unnecessary to describe the means of separating the metal, which may be finally obtained either as a dark-gray powder or in heavy iron-gray bars, which are very hard, and difficult of fusion. Aqua regia and nitric acid convert it into tungstic acid. When 10 parts of this metal are alloyed with 90 of steel, a mass of extraordinary hardness is obtained.

T. forms three compounds with oxygen—viz., a dioxide (WO_2), or tungstous oxide, which is obtained in the form of a brown powder by heating tungstic acid to low redness in a current of hydrogen; an oxide, W_2O_5, which may be regarded as a compound of the other two; and trioxide, or tungstic oxide, or anhydride (WO_3). Independently of *tungstic anhydride*, there are two modifications represented by the formulæ, M_2WO_4 and $M_2WO_4.7H_2O$, which are known as *tungstic* and *metatungstic acids* respectively. Various tungstates have been formed and examined. Of these, the most singular is tungstate of tungsten (W_2O_5, or WO_2,WO_3), which is of a splendid blue colour; and tungstate of sodium, which answers admirably as a means of preventing muslin, &c., from bursting out in a flame, when brought in contact with fire. It is unnecessary to notice the metatungstates, or the sulphides, chlorides, &c., of tungsten.

TUNGÛS, an ethnographic group of the Turanian family, are at the present time situated to the north and east of the Mongol group, inhabiting the vast plains stretching south from the icy sea of Siberia, between the Yenesei and the Lena, the northern slopes and valleys of the Great Altaï, and the hilly uneven tract between the Upper Amur and the Lena. The chief peoples included under this group are the Niuju, the Däurians, Tshapodshirs, Manchûs (in the south-east), and Lamûts (on the east coast). In the north, they have intermingled with the Samoyedes; in the west, with the Ostiaks, whose territory is on the other side of the Yenesei; and in the south, the Manchûs, though being gradually pushed northward by the Chinese, have for a long time exercised undisputed sway over their supplanters. Divided politically between Russia and China, the southern portion of them are Buddhists, while the tribes further north mostly practise Shamanism (q. v.), a few having, by the strenuous exertions of the Russian government, been induced to profess Christianity. The T. are partly nomad and wandering, and partly agriculturists and settled rearers of cattle. The first of these are commonly classed according to the districts they prefer to dwell in, as T. of the forests, or T. of the steppes: the former being shepherds, hunters, or fishers; and the latter exclusively shepherds. The steppe T., again, are divided according to the animals of draught they employ, into the reindeer-T., the horse-T., and the dog-T. The T. are in general robust and lively, with flat visage and small eyes, the latter characteristics, however, being much less prominent in them than in the Kalmucks. A portion of the Chinese Tungûs constitute the Ssolon nation so celebrated as warriors in Chinese modern history. The Tshapodshirs tattoo their faces.

TUNICA′TA, a class of acephalous molluscs, having the body enclosed not in a shell, but a soft elastic tunic, which is perforated by two apertures, and is composed of a substance resembling Cellulose (q. v.). The T. are extremely numerous, and are found in all seas. The *Ascidiæ* (q. v.) belong to this class, and the *Sulphidæ* (q. v.).

TUNING-FORK, a contrivance for regulating the pitch of the voice or of a musical instrument. It consists of two prongs of steel springing from a handle, and so adjusted as to produce a fixed note when struck. It is usually tuned in C  in Britain, and in A  in Germany. In consequence of the absence of any universally recognised standard, there is even in this country a considerable variety in the pitch of the tuning-fork. Messrs Broadwood employ three forks of different pitch to tune their pianofortes: one corresponding to the Philharmonic standard of 30 years back for instruments used for the accompaniments at ordinary concerts; another somewhat higher for pianofortes meant to take part in orchestral compositions; and a fork of still higher pitch, adopted for the present opera and Philharmonic standard, which is about a semitone higher than the standard of 30 years ago. A fork has lately been invented in Germany capable of adjustment to different standards of pitch, by means of a movable brass slider, fitted with a screw, there being indications on the prongs of the positions of the slider which give the pitch adopted by the principal orchestras in Europe.

TU′NIS, a country of Africa, and one of the Barbary States, is bounded on the N. by the Mediterranean, on the W. by Algeria, on the S. by the Desert, and on the E. by Tripoli and the Mediterranean. Its greatest length from north to south is about 440 miles; its average breadth, 160; area, upwards of 75,000 sq. m.; pop., according to latest authorities, 2,000,000. T. is traversed by branches of the great Atlas range, which, in fact, has its proper termination here. The northern coast is rocky and steep, with numerous bays, of which the largest is the Gulf of Tunis; and two of its promontories, Capes Blanco (*Râs-el-Abid*) and Bon, are the most northern in Africa. The eastern coast, on the other hand, is flat, sandy, and infertile, like that of Tripoli, but has two large gulfs, Hammamet and Cabes (the *Syrtis Minor* of antiquity). The southern part of T. belongs to the desert steppe known as Belud-el-Jerid. There is only one fresh-water lake of any consequence, that of Biserta or Bensart, near the north coast. The brooks and torrents of T. either lose themselves in the sand, or find their way to the sea after a short course. None are navigable. The longest is the Mejerdah (the *Bagradas* of the ancients), which flows in a generally north-eastern direction into the Gulf of Tunis. Other streams are the Ved-el-Milianah and the Ved-el-Kebir. There are several mineral springs in the country. The climate of T. is fine, and the soil exceedingly fertile, so that, in spite of a very poor knowledge of agriculture, wheat, barley, maize, dhurra, pulse, olives, oranges, figs, grapes, pomegranates, almonds, and dates are abundantly produced. The culture of oil is more attended to, and is very lucrative. Great herds of cattle are fed on the plains; the sheep are famous for their wool; and the horses and dromedaries are no less celebrated. The chief mineral products are sea-salt, saltpetre, lead-ore, and quicksilver. In the vicinity of the sea-coasts

considerable manufacturing and trading industry is manifested, more particularly in the cities of Tunis and Susa. Wool, olive-oil, wax, honey, soap, hides, coral, sponges, dates, wheat, and barley are the principal exports. Cloth, leather, silks, muslins, spices, cochineal, and arms are transported by means of caravans to the interior of Africa, whence in exchange are brought for exportation to European and other countries, senna, gums, ostrich-feathers, gold, and ivory.

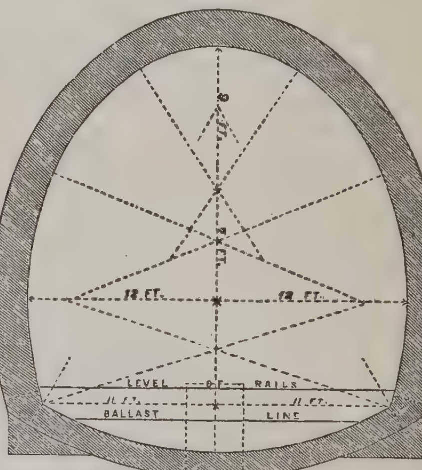
The predominant race is of Arabic descent, but there are many Berbers, especially in the interior. The territory of T. corresponds pretty nearly with that of ancient Carthage; and for a sketch of its pre-Christian history the reader is referred to the articles CARTHAGE, ROME, HANNIBAL, HAMILCAR, SCIPIO, JUGURTHA, &c. Its subsequent fortunes, down to 1575, are interwoven with the general fortunes of Barbary (q. v.); but in that year, Sinan Pasha conquered and incorporated it with the Ottoman Empire, and gave it a new constitution. The government was placed in the hands of a Turkish pasha, a divan or council, composed of the officers of the Turkish garrison, and the commander of the Janizaries. After a few years, however, an insurrection of the soldiery broke out, and a new government was established, the head of which was a 'Dey,' possessing very limited authority; the chief power being at first exercised by the military divan. Gradually, however, an officer with the title of 'Bey,' whose original functions were confined to the collection of tribute and taxes, acquired a supremacy over the other authorities, and finally obtained a kind of sovereignty, which Murad Bey succeeded in making hereditary. The family of Murad Bey ruled in T. for 100 years, and gained considerable renown both by their conquests on the mainland, and their piratical enterprises against Christian powers at sea. Nevertheless, the internal history of T. is, on the whole, little more than a series of palace revolutions, Janizary insurrections, and court intrigues. During the 18th c., it became tributary to Algiers. About the beginning of the 19th c., Hamuda Pasha threw off the Algerian yoke, subdued the Turkish militia, and created a native Tunisian army; in consequence of which T. virtually attained independence. It sends, however, yearly a tribute to Constantinople. The recent rulers, Achmet Bey (1837), Mohammed Bey (1855), and Mohammed Sadyk Bey (1859), have proved liberal, enlightened, and reforming sovereigns. Through their efforts, the slave-trade has been suppressed; numerous obnoxious and oppressive taxes and monopolies repealed, political equality established, and even municipal liberties secured in the capital itself.

TUNIS, capital of the African state of the same name, lies on the west side of a small lake or lagoon, near the south-west extremity of the Lake of Tunis, about 3 miles from the ruins of ancient Carthage. It occupies rising ground, and both the city proper and the suburbs are surrounded by walls. The streets are narrow, unpaved, and dirty, but the bazaars are well furnished, and many of the mosques are really splendid, particularly the mosque of Jussuf, which has beautiful marble pillars. The palace of the bey is probably the finest building in T.; the ceilings glitter with gold, and carmine, and azure. All the principal rooms open into a large courtyard paved with marble, and surrounded by arcades supported on marble columns, while fountains everywhere diffuse a perpetual and delicious coolness. The citadel, begun by Charles V., and finished by Don John of Austria, is interesting from its collection of old arms, and was formerly the great slave prison of Tunis. There are also Roman Catholic and Greek churches, Jews' synagogues, an Italian theatre, and large barracks in Tunis. About a mile and a half west of the city, in a bare, verdureless plain, stands the *Bardo*, or summer residence of the bey, the interior of which is gorgeous. T. has silk and woollen manufactures, as shawls, tapestries, mantles, burnuses, caps, turbans, coloured cloths, also leather, soap, wax, and olive oil, all of which it exports, together with grain, fruits, cattle, fish, ivory, gold-dust, coral, &c. Pop. state at about 125,000.

The lagoon or Lake of Tunis is shallow, and communicates with the *Gulf of Tunis*, an inlet of the Mediterranean, by a narrow strait or channel called the Goletta. The gulf itself is 45 miles broad at the entrance—between Cape Bon and Cape Farina—and extends inland for 30 miles.

TUNKERS. See SUPPLEMENT in Vol. X.

TUNNEL. Tunnels are passages constructed under ground to carry roads, railways, canals, or streams of water. Tunnelling, which has long been in use for roads and aqueducts, has of late received a great development in the construction of railways. At the present time, there are believed to be upwards of 80 miles of railway tunnels in Great Britain in constant use for the passage of trains; and as their cost averages from £45 to £50 per yard, a total of about seven millions sterling has been expended in their construction. The adjoining figure gives the ordinary section of a tunnel to carry a double line of



Transverse Section of a Tunnel on the Leeds and Bradford Railway.

railway. In tunnels of considerable length, as the progress made by working from the two ends would be very slow, it is considered advisable to commence the work from many points of its length; for this purpose, shafts or pits are made at these points down to the level of the tunnel. Of these shafts, some are temporary, and only kept open during the progress of the work; others are permanent, and for the purpose of ventilating the tunnel when in use. These shafts have to be large enough to allow the ascending and descending skips or buckets containing the excavated materials to pass one another. For the temporary shafts, an elliptical shape is found to give the greatest room for this purpose at the least expense. Square shafts are to be avoided, on account of the difficulty of excavating the corners in rocky strata

As the shaft descends, its sides are lined with timber-planks, supported by strong timber-frames, about five feet apart. The permanent shafts, when the material is not of rock sufficiently solid, are lined with brick-work or masonry, built in lengths, as the shaft proceeds downwards. These permanent shafts are generally made circular in section, and it is found better to place them three or four yards from the side of the tunnel, communicating with it by a small passage. This is convenient in the construction, and also is a useful refuge for workmen subsequently during the passage of trains. These shafts are generally made about ten feet diameter. They are sunk a few feet below the floor of the tunnel, to form a pit for the collection of the water from the workings, which is hauled to the top in barrels or buckets. The raising of the excavations and the water, and the lowering of building materials, and of the workmen, is done by a windlass, a horse-gin, or steam-power, according to the extent of the work. On the completion of the shaft, the tunnel is commenced in both directions from its bottom; and in the case of ordinary rock, it is found convenient to commence by making a small adit, or passage, along from shaft to shaft, through the whole length of the tunnel; this is made six or seven feet high, and the top of it placed at the level of the top of the tunnel. When this is completed, the correct centre line is marked out in it throughout the tunnel; the adit is then enlarged to the shape and size of the arch of the tunnel, which is built in, and then the excavation is completed, and side-walls built up to underpin the arch. In cases where the material is soft and full of water, the full section of the tunnel is generally carried forward at once, and in such cases an invert has to be built between the side-walls, to withstand the upward pressure, as the pressure of soft material has the character of a fluid pressure, and presses the tunnel on all sides. The excavation is then done in lengths of about 24 feet, which is firmly secured with poling-boards and larch bars, and securely shored; the centres are then set, and the brick-work built up. The timber bars are generally drawn out when the brick-work is carried up, and the holes they leave rammed tight with clay; but they have sometimes to be built in. When the quantity of water is very great, an adit is driven through the tunnel, at the level of its floor, before the work is begun, to allow the water to run off.

Tunnels are generally made straight, but sometimes they are curved; this is done that they may pass under the lowest part of the hill, in order that the shafts may be as short as possible. They are frequently constructed on steep gradients, but as the trains experience some resistance from the air in passing through them, it is advisable not to make them so steep as the gradients in the open air.

The most remarkable tunnel of the present time is the Mont Cenis* tunnel. This tunnel connects the railways of France and Italy, and is on the direct railway route from Paris to Turin. The length of this tunnel is 7 miles 4¾ furlongs. It is 434 feet higher at Bardonnèche, on the Italian side, than at Modane, on the French side. On this account, it is on a gradient of 1 in 45½ from Modane to the middle, and thence it falls 1 in 2000 to Bardonnèche, this latter fall being sufficient to run off the water. The dimensions at Modane are 25 feet 3½ inches wide at base, 26 feet 2¾ inches at widest part, and 24 feet 7 inches high, the arch being nearly semicircular. At Bardonnèche, it is 11¾ inches higher. It is all lined with stone-masonry, except at the Bardonnèche end, where the arch is of brick.

The work was begun in 1857, and was at first done in the usual way by hand; but in 1861, the perforating machines described below were introduced on the Italian side, and two years later (1863) on the French side. On the 30th June 1863, the tunnel had been driven 2800 yards, and the rate of advancement was 9½ feet per day. The engineers expected, by improvement in the machines, to obtain a more rapid advancement. This, however, they did not succeed in doing to any great extent, for in October 1866, just one-half the distance, or 6680 yards, had been pierced, showing a constant rate of 9½ feet per day. At this rate, it was expected that the tunnel would be completed in 1872; but it was finished in 1871. A premium was to be paid by the French government to the Italian government, who did the work, for each year by which a term of 25 years, counting from 1862, was reduced. The French government was also to pay £1,287,000 for the construction of one-half the tunnel when completed.

This great work, which appeared almost impracticable to ordinary methods of tunnelling by manual labour, was rendered practicable by machinery introduced by the engineers, Messrs Sommeiller, Grandis, and Grattoni. The great difficulty lay in the fact that, from the great height of the mountain, shafts were impracticable, and progress could only be made from each end. The ventilation also presented serious difficulties. M. Sommeiller perfected a small machine, weighing 6 cwt., which bored a hole 1¼ inch diameter and 3 feet deep in twenty minutes; the time taken by two miners working by the ordinary method being two hours. Eleven of these machines were placed on a movable support, and were capable of working at almost any angle. Three or four large holes were bored in the centre of the heading, and round these other holes of the ordinary size, in all 80 holes. The large holes were not fired, but were for the purpose of weakening the rock. The others were then fired in succession and in detachments, beginning with those nearest the centre, and working outwards. The machines were worked by compressed air acting, like high-pressure steam, on a piston in a cylinder; this air was compressed outside the tunnel by water-power acting on the hydraulic-ram principle, and also by an air-pump; it was used at a pressure of five atmospheres above the atmospheric pressure, and was conveyed to the workings by a pipe 7⅞ inches diameter. After it had expended itself in working the borers, it escaped into the tunnel, and so ventilated the workings. The advanced heading was the only place where these machines were used; the enlargement of the tunnel to the full size, the building, &c., were all performed by manual labour. It was expected that upon the completion of the tunnel there would be a constant current of air from the north to the south end, as the latter is the higher end, and in a situation more exposed to the heat of the sun. In view of the great importance of the Mont Cenis route, and the uncertainty of the time of completion of the tunnel, a locomotive railway was constructed over the top of the pass. The rails are laid on the existing road, and ascend the hill in zigzag lines. The steepest gradient is 1 in 12, and on this gradient, and down to 1 in 20, a third rail is laid in the centre of the way, raised about 9 inches above the other rails. The engines are provided with two pairs of horizontal wheels, which being made to press against the centre rail, provide the adhesion necessary for ascending and descending these steep inclines. From experiments

* This is really a misnomer; the tunnel is at a considerable distance from Mont Cenis, and the chief summit under which it passes is the 'Grand Vallon' (11,000 feet high).

it has been satisfactorily proved that passenger trains will make the transit in four hours, thus saving eight hours in the journey from Paris to Turin. Upon the opening of the tunnel for travel, the rails will be taken up and the traffic transferred to the tunnel route.

TUNNY (*Thynnus vulgaris*), a fish of the family *Scomberidæ* (q. v.), found in the Mediterranean and in the Atlantic Ocean, but particularly abundant in the Mediterranean, where the T. fishery is of great importance. It occasionally, but rarely, occurs on the British coasts. The genus *Thynnus* is closely allied to *Scomber* (see MACKEREL), but has the dorsal fins close together, the detached finlets more numerous. The T. is a very large fish, sometimes nine feet in length, and weighing 1000 lbs., or even more. Its form is much thicker than that of the mackerel; its tail so widely forked as to be crescent-shaped. It is very plentiful near Constantinople, where it appears in shoals, sometimes so crowded that it may even be taken with the hand. The chief T. fisheries of the present day, however, are on the coasts of Spain, Italy, and Sardinia. The Phœnicians established a T. fishery at a very early

Tunny (*Thynnus vulgaris*).

period on the coast of Spain, and the T. appears on Phœnician medals of Cadiz and Carteia. Salted T. was much esteemed by the Romans, and was called *Saltamentum Sardicum.* The T. is generally captured by means of nets arranged in a funnel-like form, the fish entering the wide mouth of the funnel, and being gradually driven to the narrow end, where they are killed by lances and harpoons. The line of nets is often more than a quarter of a mile long, and costs about 6000 dollars.—The AMERICAN T. (*Thynnus secundo-dorsalis*) is found on the coasts of New York, and thence northwards to Nova Scotia. It sometimes attains a length of twelve feet. It is pearly black above, silvery on the sides, and white below. Its flesh is much esteemed. It also yields much oil, which is obtained by boiling the head and the belly. Twenty gallons of oil are often obtained from a single fish.

To the same genus with the T. belong the Bonito (q. v.) and the Albacore or Albicore (*T. albacorus*), which inhabits the West Indian seas, and is esteemed for the table. The name Albacore, however, seems to be often given to different species of this family, inhabiting tropical seas, and sometimes to the T. itself.

TUPAIA. See BANXRING

TU'PELO (*Nyssa*), a genus of trees of the natural order *Cornaceæ*, natives of North America, chiefly of the middle and southern parts of the United States; having simple alternate leaves, mostly entire, greenish inconspicuous flowers at the extremity of long stalks, the fruit a drupe. *N. multiflora* attains a height of 60—70 feet. It is often called SOUR GUM TREE. *N. tomentosa*, the LARGE T., is a lofty and beautiful tree, remarkable for the extraordinary enlargement of the base of the trunk, which is sometimes eight or nine feet in diameter, while at no great height the diameter diminishes to fifteen or twenty inches. The fruit resembles a small olive, and is preserved in the same way by the French settlers in America. *N. candicans* or *capitata*, the OGECHEE LIME or SOUR GUM TREE, is a small tree, of which the fruit is very acid, and is used like that of the lime. The wood of all the species is soft, that of the large T. remarkably so.

TUPPER, MARTIN FARQUHAR, D.C.L., F.R.S., a poet rather popular than great, was born on 17th July 1810. His father, Martin Tupper, was a well known London surgeon, of a family originally German, which had long been settled in Guernsey. Martin T. was educated at the Charter-house, and afterwards at Christchurch, Oxford. On leaving college, he entered himself as a student at Lincoln's Inn, and was called to the bar in 1835; but literature had more charms for him than the law, which he never seriously prosecuted. In 1832, he published anonymously a small volume of poems, which attracted little attention. For this lack of success, he was, however, amply repaid on the appearance, in 1839, of his *Proverbial Philosophy.* The popularity of this work in England, and still more in America, has ever since been immense, and almost unprecedented. The critics have indeed been less kind to it than the reading public; and the fame of Mr T. has long been a topic of mirth to the wits of the literary guild; but from the serene height of his fortieth edition an author can perhaps afford to smile at the attacks of the envious generation below. A fair criticism would probably adjudge that, while there is nothing in Mr T.'s *Proverbial Philosophy* to justify its enormous success—so far as mere circulation is success—the book is yet something better than the mere conglomeration of stupid platitudes, which its detractors so confidently proclaim it to be. Besides this work, on which his reputation—such as it may be—rests, Mr T. has published *The Crock of Gold*, a tale; *Geraldine*, a sufficiently ludicrous attempt to complete Coleridge's inimitable fragment *Christabel*; with various other works in prose and verse, which it is quite unnecessary to enumerate, inasmuch as no one of them has succeeded in making the least impression on the public.

TURA'NIAN LANGUAGES. In opposition to *Iran*, the name of their own country, the Persians from the earliest times called the countries lying to the north of it Turân, and this name is still frequently used as synonymous with Turkestan. The term Turanian derived from it has been adopted by philologists, in contrast with Aryan (q. v.), to designate a family of languages comprising 'all languages spoken in Asia and Europe (including Oceania), and not included under the Aryan and Semitic families, with the exception of Chinese and its cognate dialects.' The languages of this family are of the agglutinate order (see PHILOLOGY). Max Müller classes them in two great divisions, the Northern and the Southern. The Northern division falls into five sections—the *Tungusic*, *Mongolic*, *Turkic*, *Finnic*, and *Samoyedic* Of these, the Tungusic dialects, which extend north and west from China, are the lowest in organisation, being, some of them, nearly as destitute of grammatical forms as the Chinese. The Mongolic dialects are superior to the Tungusic, although the different parts of speech are hardly distinguished; both branches, however, are believed to be manifesting symptoms of grammatical development. The Turkic dialects, of which the Osmanli
